Contemporary with Cervantes was Lope de Vega (see VEGA), the idol of his time, the 'prodigy of nature' (*monstruo de la naturaleza*), as he was called on account of the immense mass and great variety of his writings. Almost every branch of literature was familiar to him. Of dramas alone he wrote over 2000, besides a great body of lyric verse, epic and mock epic, novels both pastoral and of adventures, and criticisms. It is by his dramas that he is best known, and especially by those of cloak and sword (*capa y espada*). These within certain well-defined limits afford considerable scope for variety. The scene is invariably laid in some Spanish town. The principal characters are two lovers, whose adventures and somewhat stilted dialogue are parodied and relieved by those of their servants, one of whom

is generally the *gracioso* or buffoon, whose homely pleasantries sometimes jar disagreeably in the midst of fine and solemn passages. The metre of the Spanish drama is generally the same as that of the ballads; some variety, however, both of grouping of rhymes and of metre is admitted. A distinctive feature is the exceeding intricacy of the plots. This characteristic is so marked as to have led several critics to believe that a Spanish drama requires a Spanish audience to follow it intelligently. The great amount of the productions of Lope de Vega precluded all attempt at finish. His verse, however, is always flowing, and he generally attains success by thoroughly carrying out his own maxim that the drama is a purely popular form of literature, and that the only critics to be regarded are the mass of those who pay their money at the theatre-door. Calderón de la Barca (see CALDERÓN) outlived the golden age of the drama of his country. More philosophic, careful, and with a higher ideal than Lope, he is generally incapable of curving out his gigantic enterprises, and is, broadly speaking, a poet of fine passages rather than a dramatic author of high merit. In attempting sublimity he frequently becomes bombastic and misty, and is deeply infected with the bad taste of his time. He perfected the *auto sacramental*, a religious play, or rather a dramatised theological discussion, in which such characters as Conscience, Free-will, Hope, and the cardinal virtues take part. On these, to modern taste, somewhat dull compositions, in which Christian theology is frequently jumbled up with pagan mythology, Calderón lavished a great deal of his best verse, and to them his reputation amongst his contemporaries was largely due. Equal to Lope or Calderón as dramatists, though inferior as poets, are Tirso de Molina (see TELLEZ) and Moreto. The former handled to perfection his native language, and is, more than any other, characteristically a Spaniard of his time. His defects are the want of a high ideal and the frequent coarseness of his language. Outside his own country he is chiefly known as the author who first dramatised the story of Don Juan Tenorio, the *Burlador de Sevilla*, a theme whose impressive nature he well knew how to take advantage of. Moreto is the most correct of Spanish dramatists, and his *Desdén con desdén* merits special mention, even in an age which produced, besides the authors already mentioned, Rojas and Alarcón (q.v.). The number of dramas produced at this time is almost incredible, and some, even of the anonymous ones, are such as in a less fertile age would have sufficed to found a reputation.

Spanish eloquence has always had a tendency to become bombastic; mannerisms and affectation of the worst kind have been mistaken for cultured style; extravagance of metaphor was rife even at the best period (see EUPHUISM); but when literature began to decay all these defects became more marked. The typical representative of this *culto* school is Luis de Góngora (see GÓNGORA), a poet who enjoyed great popularity in the golden age, and whose example probably did much to hasten a climax which had already become inevitable. In his youth he wrote simply and correctly short lyric pieces of great beauty. It is difficult to believe that this is the same Góngora who, a few years later, produced the *Soledades* and *Polyfemo*, poems so obscure, bombastic, and crammed with *conceits* that before his death they required lengthy commentaries. Amongst those who protested against the tendency of the times, whilst frequently allowing themselves to be carried away by it, was Francisco de Quevedo y Villegas (see QUEVEDO), the bitter satirist and writer of trenchant verse. Extremely versatile, his writ-

ings include erotic verse, light lyrics, essays on government, picaresque novels, and theological discussions. In his merits and defects he closely resembles Swift. The best known of his works are his *sueños*, or visions, in which the motives and manners of his time are held up to ridicule with a mastery and unsparring hand.

At the end of the 17th century the sun of Spanish glory set, and with it the sun of Spanish literature, so suddenly and completely as not to leave an afterglow behind it. Of the succeeding century only a few names deserve mention. Padre Isla (q.v.) in *Fray Gerundio* ridiculed the low ebb of education, and particularly of pulpit oratory, with wit and good sense worthy of a better age. Samaniego and Yriarte wrote some clever fables in the style of the inimitable Lafontaine. The Academy, founded during the first half of the 18th century, produced the magnificent dictionary which is its chief claim to the gratitude of scholars. When literature seemed at its lowest ebb, and nothing found favour unless slavishly imitated from the French, Moratín (q.v.) came to add one more name to the glorious list of dramatists.

The despotic rule of Ferdinand VII. (d. 1833) drove into exile practically all writers of liberal tendencies, but the successful production (1835) of the play, *Don Álvaro* by the Duque de Rivás, was a victory for romanticism. A new period of Spanish literature began, characterised by a direct realism (apt to degenerate into over-emphasis) and by a distinctly national (or more often, regional) spirit. The first of these regional novelists was Fernán Caballero, whose *Gamota* is marked by keen personal observation, but the first half of the 19th century was rendered noteworthy by a group of poets: Espronceda, passionate and impetuous; Zorrilla, more restrained, but also more facile; Becquer, author of some charming lyrics; and Campaño, whose delicate craftsmanship found expression in *Doloras*. Echegaray produced many plays of the sentimental type, while the poet Núñez de Arce won fame with his virile *Gritos del combate*. The development of the novel (often relying more on characterisation rather than on plot), however, has been the predominant feature of modern Spanish literature, and *Pepeita Jiménez* (1874) of Valera and *El Sombrero de tres picos* (1874) of Alarcón still remain two of the most outstanding examples. Four novelists, in particular, connect the 19th with the 20th century: Pereda, almost reactionary in spirit, described the picturesqueness and rough grandeur of Santander; Emilia Pardo Bazán wrote delightfully of Galicia; Pérez Galdós, who has been compared to Dickens in his development of characters and in his love of the fantastic, helped to form a Spanish national consciousness with his huge series of historical novels, *Episodios Nacionales*; while Valdes interprets Asturias with a keen sense of humour and psychological understanding. There are four novelists belonging more particularly to the 20th century: the forcible Blasco Ibáñez, who is at his best in describing the humble life of Valencia, devotes himself in some of his later works to controversial social problems, but in some respects is too much influenced by the French naturalistic school; intense energy is also characteristic of the Basque, Pío Baroja, whose novels give a vivid and truthful presentation of life, but are somewhat unequal in construction; 'Azorín,' also a good critic, draws homely scenes with great detail and delicacy; but the art of Miró, equally sensitive, is almost more spontaneous. Ayala and Valle Inclán are both novelists and poets; the former (from Asturias) views life from an earnest detached point of view, while the style of the latter (from Galicia) is graceful, rhythmical, and subtle. The novelist León and the poets Jiménez and Asunción

Silva are the best of the younger school, but of the whole, the influence of the French *symboliste* has been very penetrating. In the field of drama, the cosmopolitan Benavente, a Nobel prize-winner, with his great powers of vital character-drawing, has a worthy successor in Martínez Sierra. The Quintero brothers specialised in the writing of comedies, often for the *género chico* (short plays or sketches with songs and music). As regards scholarship and learning, two names stand out brilliantly in the 19th century—those of Mila y Fontanals and of Menéndez y Pelayo; while the philosophers Unamuno and Ortega y Gasset, both men of extremely wide culture, and the critic Menéndez Pidal, belong more to the 20th century. Periodic literature of a not very high order is abundant. There has always been considerable literary activity in Spanish America, but few writers of any special importance appeared before the Nicaraguan, Rubén Darío (q.v.), one of the most brilliant of the modern poets, with a mastery of technique allied to genuine lyrical powers. The Uruguayan, Rodó, specialised in æsthetic criticism.

Catalan Literature.—The intercourse between Catalonia and Provence has been great from the earliest times. The troubadours of Provence carried with them across the Pyrenees their own language as well as their own poetical forms. Their influence may be seen in the works of Raymond Lully, whose poem 'Despair' (*Lo Desconort*) is deeply impregnated with their mannerisms. At the later end of the 14th century a consistency of the *gay saber* was founded at Barcelona in imitation of the one already existing at Toulouse. From this may be dated the partial emancipation of Catalan verse. Two Valencian poets distinguished themselves in their native language. Ausiàs March, whose songs of love and songs of death are fine in spite of intentional obscurity, and Jaume Roig, whose bitter satire, *The Ladies' Book*, is supposed to contain details of his own life. Roig died in 1478, and at the union of Castile and Aragon Catalan sank to the position of a dialect. In prose the principal monuments of old Catalan are the works of Lull, including the interesting *Book of the Order of Knighthood*; the *Chronicles*, some of which are interesting both in matter and manner, especially that of Ramón Muntaner; and one romance of chivalry entitled *Tirant lo Blanch*, an exaggerated example of the defects of the class. In the 19th century a successful movement (not unconnected with politics) was set on foot to make Catalan, which had come from the Middle Ages virtually unchanged, a literary and not merely a popular language. Some of the verse of Verdaguer is very charming and natural, while more recent poets are Maragall, Carner, and López-Picó. The shadow shows of Robredo at the beginning of the 19th century can be said to have started the modern Catalan theatre, of which the most vigorous and dramatic exponents have been Guimerà, Gual, and Rusiñol, while contemporary prose is well represented by Eugen d'Ors.

In Galician, which has never been a literary language, few books exist, with the exception of collections of popular songs.

CASTILIAN.—The standard English history of Spanish literature is that of Fitzmaurice-Kelly (new ed. 1926, superseding all former editions), but see also the general histories by Ticknor (6th ed. 1888), Butler-Clarke (2d ed. 1909), Ford (1919), and Northup (1925), all in Eng.; by Becker (1904, in Ger.); by Castro (1890), César Barja (1923-24), and Hurtado and Palencia (2d ed. 1925), all in Span. For the period up to the 16th cent. see the work by Amador de los Ríos (1861-65), for the Middle Ages, the work by Wolf (1859, in Ger.), and for contemporary literature, works by Mandariaga (1923) and A. F. G. Hell (1925), in Eng. For the drama in the time of Lope de Vega, in the 17th cent., and in contemporary

times respectively, see works by Renuert (1909, in Eng.), Morel-Fatio (2d ed. 1923, in Span.) and González-Blanco (1917, in Span.), as well as general histories by Castel (1882, in French) and Schäffer (1890, in Ger.). See also various books by Menéndez y Pelayo, including *Orígenes de la Novela* (1905-7) and *Historia de la Poesía Castellana* (1911-13). There are anthologies by Ford (1901), Fitzmaurice-Kelly (1913), and Farnell (1920); and histories of Spanish-American literature by Menéndez y Pelayo (1911-13, in Span.) and Coester (1917, in Eng.).

CATALAN.—See Mila y Fontanals, *De los Trovadores* (1861); Tubino, *Historia del renacimiento contemporáneo* (1880); Denk, *Altatalanische Literatur*; histories by Rubió y Ors (1880), d'Oliver (1919), and studies on the drama by Urquiza (1911), Curet (1919), all in Spanish; anthology by Amade (1908).

Spalato, or less correctly SPALATRO (Slav. *Split*), the busiest town of Dalmatia, stands on the Adriatic, 160 miles SE. of Fiume. Here in a beautiful situation the Emperor Diocletian built a colossal palace (*Salona Palatium*, whence perhaps Spalato, though more probably from *špalatov*), to which he retired when he abdicated the throne in 305. The palace faced the sea, looking southwards; its walls were from 570 to 700 feet long and 50 to 70 feet high, and enclosed an area of 9½ acres. It stood square like a Roman camp, and had a gate in the middle of each side, and was of the most solid construction. Architecturally it is of the highest interest in that it contains several features that prefigure the architectural styles and devices of modern times. Inside the palace the roads connecting the gates crossed at right angles in the middle, and two of the four courts thus formed were each occupied by a temple (or similar building), one to Æsculapius, the other to Jupiter. So at least says an ancient tradition, though some modern authorities claim the latter, and others the former, as the mausoleum of the emperor. The temple of Jupiter is externally an octagon with a colonnaded peristyle and internally a circle covered by a dome. Where the projecting orifice was built there now stands a tower built in the 14th and 15th centuries, thoroughly restored in 1891-92. Since the year 650 this temple has been a Christian cathedral; it contains a magnificent marble pulpit. The interior was extensively restored in the years immediately preceding 1885. The other temple is used as a apothecary; it is of small size and rectangular in shape. All the interior buildings and nearly all the exterior walls of this gigantic palace are still standing in a fairly good state of preservation. But the interior was converted into a town in 639 by the citizens of Salona (q.v.) who escaped the destruction of their town by the Avars, and it has been occupied ever since. The existing city of Spalato lies, more than half of it, outside the palace walls. It contains a museum rich in the remains of Salona, and has a lively trade; the Lassa railway (1895-97) connecting it with Bosnia and the Danubian lands. Its industries embrace the manufacture of liqueurs (rosoglio and marschino), bricks, ropes, &c. Pop. 25,000. See ROMAN ARCHITECTURE; and books on the palace by R. Adam (in Eng. 1864) and G. Niemann (in Ger. 1910).

Spalding, a Dutch-looking town on the Welland in Lincolnshire, 14 miles SW. of Boston, with a fine church (Decorated and Perpendicular), built in 1284 and restored by Sir G. Scott. A castle and a monastery existed here prior to the Conquest. The grammar-school, of which Bentley was master in 1682, was founded in 1568; new school buildings were erected in 1881. Ayscoughfe Hall, dating originally from 1420, was the residence of the antiquary Maurice Johnson, who helped to found the Society of Antiquaries and the Spalding

Gentlemen's Society (1710; resuscitated in 1889). Spalding lies in the centre of the fertile Fen District (see BEDFORD LEVEL), and has an active trade in agricultural produce. The river is navigable up to the town for vessels of 80 tons. Pop. 14,000.

Spalding, JOHN (fl. 1824-45), was the commissary clerk of Aberdeen and diarist, after whom is named a well-known northern Book-club (q.v.).

Spallanzani, LAZARO, naturalist and traveller, was born at Scandiano, in the duchy of Modena, Italy, on 12th January 1729. After studying, at Reggio di Modena and Bologna, natural science, mathematics, the classical tongues, law, and other subjects, he was in 1754 appointed to the chair of Logic, Metaphysics, and Greek at Reggio, and soon afterwards was transferred to Modena. But he took the greatest interest in natural history and physiological questions. Amongst other things his attention was directed to the doctrine of spontaneous generation propounded by Needham and Buffon, which after careful study and experiment he overturned. On the re-establishment of the university of Pavia Spallanzani was appointed (1768) professor of Natural History and keeper of the museum, which he greatly enriched with fishes, crustacea, and testacea, the fruits of his numerous excursions. In 1785-86 he spent nearly a twelvemonth in Turkey engaged in scientific observation, and during the year 1788 visited Naples whilst Vesuvius was in eruption, the Lipari Isles, and Sicily, and wrote an account of his inquiries, *Viaggi alle due Sicilie* (6 vols. 1792). He died of apoplexy, 11th February 1799. In *Dissertatione de Fisica Animale e Vegetale* (2 vols. 1780) he clearly demonstrated the true physiological nature of digestion, and established, on the basis of experiment, the respective functions of the spermatozoa and the ovum in reproduction.

Span, a measure of length, being the distance between the tips of the thumb and little finger when the fingers are expanded to their fullest extent. This space averages about 9 inches, which accordingly is the fixed measure given to the span.

Spandau, a town and first class fortress of Prussia, since 1920 part of Berlin, is situated at the confluence of the Havel and the Spre. The principal defence of the capital on the west side, it has very strong modern fortifications, including a citadel. In the 'Julius tower' of this structure was preserved in gold the 'Reichskriegsschatz' of £6,000,000 that the government, according to a law of 11th November 1871, kept in reserve for a great war. Spandau has government munition works and an arsenal. Pop. (1875) 27,630; (1890) 44,611; (1910) 84,855; (1919) 95,474. One of the oldest towns of Brandenburg, it was a favourite residence of the electors. It surrendered to the Swedes in 1631, to the French in 1806, and in 1813 to the Prussians.

Spanheim, FRIEDRICH, theologian, was born at Amberg, January 1, 1600; studied at Heidelberg and Geneva; visited Paris and England; was appointed in 1631 to the chair of Theology at Geneva, in 1641 at Leyden; and died there, April 30, 1648. He contributed to the controversy with Amyrant *Disputatio de gratia universalis* (1644), &c.—EZECHIEL SPANHEIM, son of the foregoing, was born at Geneva, December 7, 1629, studied at Leyden, and was appointed professor of Rhetoric there in 1651. He next became tutor to the sons of the Elector Palatine, and with them travelled in Italy and Sicily. In 1665 he represented the Palatinate and Brandenburg as resident in England; in 1680 he went for nine years to Paris as ambassador extraordinary. He took part in the peace of Ryswick, later went on missions both to Paris and

London, and died at the latter, 7th November 1710. He had great learning in the history of ancient law and in numismatics, and his *Dissertationes de usu et præstantia numismatum antiquorum* (best ed. 1706-18) and *Orbis Romanus* (1704) made his name widely known.—FRIEDRICH SPANHEIM, his brother, was born at Geneva, May 1, 1632, studied at Leyden, was appointed to the chair of Theology at Heidelberg in 1655, at Leyden in 1670, and died there, May 8, 1701. He defended Calvinism against Descartes and Cocceius. His collected works fill 3 volumes (1701-3).

Spaniel, one of the longest established breeds of dogs. Dr Caius gives a description of the spaniel in his treatise *Of English Dogges* (1576). The working spaniel may be divided into the Clumber, the Sussex, and the Field Spaniel. The clumber derives his name from the estate of the Duke of Newcastle, who originally imported them from the kennel of the Duc de Noailles, and bred them for many years at Clumber Castle (q.v.). The pure breed was guarded with jealousy. Clumbers are usually worked in a team of four or five; as they generally hunt in silence, they are extremely useful in thick cover, the game not being alarmed without cause. In appearance the clumber is a handsome lemon and white dog, short in the leg, long in body, coat like a setter, a massive head with large drooping ears.

The Sussex is also a variety of long standing, though the pure breed was only resuscitated in 1870 with great difficulty. In colour the Sussex should be a 'golden-liver' or brown, otherwise it closely resembles the clumber.

The Black Spaniel is bred mainly from Sussex blood. The 'cocker' and the 'springer' are names indiscriminately applied to field spaniels of unknown breeding; they are generally liver and white, and are probably cross-bred Sussex.

Though there are records of the existence of an English water-spaniel, yet the breed has been entirely eclipsed by the Irish water-spaniel. The Irish dog resembles a large poodle in face and size, an untrimmed coat curling all over the body; in colour it should be a reddish liver.

Toy Spaniels, though identical in name, have little in common with the working spaniel. They are divided into the black-and-tan King Charles, first brought into notice by Charles II., and the red and white Blenheim, established by the Duke of Marlborough. The toy spaniel should not weigh more than 10 lb., and should have a short turned-up face like a pug-dog. From their long coats and small size these dogs are only fitted for pets, but are bright and cheery in disposition.

Spanish Fly. See CANTHARIDES.

Spanish Legion. See EVANS (DE LACY).

Spanish Main (i.e. *main-lent*), a name given to the north coast of South America from the Orinoco to Darien, and to the shores of the former Central American provinces of Spain contiguous to the Caribbean Sea. The name, however, is often used of the Caribbean Sea itself, especially in connection with the Buccaneers (q.v.).

Spanish Marriages. See GUZOT.

Spanish Needles (*Bidens bipinnata*), a worldwide pest of cultivation of American origin, spreading by means of its hooked fruits. The name is given to other plants of the genus, to which belongs also the comparatively innocent Bar-marigold.

Spanish Succession. See SUCCESSION WARS.

Spanish Town. See JAMAICA.

Spar (Ger. *Spath*), a miners' term for any bright crystalline mineral, used in books for certain minerals—bitter spar, brown spar (see

DOLOMITE), calc spar, calcareous spar, or Iceland spar (see CALCITE), Fluor Spar (q.v.), heavy spar, or barytes (see BARYTA), &c.--in which, however, it has no proper generic significance.

Sparks, JARED, American historian, was born at Willington, Connecticut, 10th May 1789, graduated at Harvard University in 1815, and became tutor in mathematics and natural philosophy there, and one of the conductors of the *North American Review*. In 1819 he was settled as a Unitarian minister at Baltimore, where he wrote *Letters on the Ministry, Ritual, and Doctrines of the Protestant Episcopal Church*. In 1821-23 he edited the *Unitarian Miscellany*, in which he first published his *Letters on the Comparative Moral Tendency of Trinitarian and Unitarian Doctrines*. In 1821 he was chosen chaplain to congress, but two years later he abandoned preaching owing to ill-health, and for seven years was proprietor and editor of the *North American Review*. In 1828 he published a *Life of John Ledgard*, and from 1834 to 1837 edited at Boston 12 volumes of the *Writings of George Washington*. In this important national work Sparks unfortunately doctored the text, and so did much to shape the priggish George Washington of myth. It was followed by the *Diplomatic Correspondence of the American Revolution* (12 vols. 1829-30), and the *Life of Gouverneur Morris* (3 vols. 1832). At this period he began the *American Almanac*, and also his *Library of American Biography*, first issued in two series of 10 and 15 vols. In 1836-40 was published his collection of the *Works of Benjamin Franklin* (10 vols.), and in 1853 his *Correspondence of the American Revolution* (3 vols.). Besides these multifarious literary labours, he was from 1839 to 1849 McLean professor of History at Harvard, and from 1849 to 1853 president of the college. He died 14th March 1866. See memoirs by Brattle Mayer (1867), G. E. Ellis (1869), and H. B. Adams (1892).

Sparling. See SMELT.

Sparrow (*Passer*), a familiar genus of birds of the family Fringillide, having a strong conical bill, the upper mandible slightly curved, the lower mandible compressed and shorter than the upper, the nostrils partly concealed by the short feathers at the base of the bill, the legs moderately long and stout, the claws sharp and curved, the tail moderately long, and nearly even at the tip. The species are not very numerous, and are exclusively found in the Old World. The Common Sparrow, or House-sparrow (*P. domesticus*), is plentiful almost everywhere in the British Islands, its distribution following cultivation even to the Outer Hebrides. It is found also throughout Europe as far as to the Arctic Circle, but not in the Faeroes, abounding particularly in the northern countries, from which its range extends eastwards into Siberia, and southwards in Africa to Lake Albert, Morocco, and Madeira. A paler variety is found in Siam, Borneo, and the Indian region as far west as southern Persia. Of all British birds the sparrow is the holdest in its approaches to man, and it is too well known to require description. Town sparrows are not mere visitors from the neighbouring country, but constant inhabitants of the town itself, with the snook of which their plumage is begrimed. The sparrow in its best plumage is not a very beautiful bird, nor so elegant in form as many others of the finch tribe; it has no melodious song, but its habits are interesting, and its frequent lively chirp is pleasing. Sparrows often congregate in great flocks, particularly in autumn. The sparrow is one of the most omnivorous of birds, devouring animal and vegetable food indiscriminately, and eating vast numbers of insects and their larvæ during summer. Their

depredations on crops have induced many farmers to use means for their destruction. They are good to eat, though little used for this purpose in Britain. It is otherwise in France, where all the small birds are sought after as articles of food. But the destruction of sparrows may be carried too far; and in France it has been followed by an increase of caterpillars, vastly more injurious to crops than the sparrows themselves. Since the young are fed upon caterpillars and insect larvæ, the killing of the fledged young has been recommended as the best method of taking advantage of the usefulness of the sparrow and at the same time checking its autumn ravages among the grain. The sparrow makes a rough and ready nest, collecting a quantity of hay or some similar material, in a hole of a wall, and lining it with feathers; sometimes, but more rarely, building a rude dome-shaped nest in the higher branches of a tree. Apart from the habitations of man, which it so much frequents, it often builds in crevices of rocks, or in cliffs on the seacoast, or under the shelter of the nests of rooks, one rook's nest sometimes covering several nests of sparrows. Several broods are produced in succession, and the breeding season is prolonged over the whole summer, one brood succeeding another. In summer the plumage of the sparrow is more brilliant than in winter, and the female is of more sober plumage than the male, exhibiting indeed little diversity of colour. In Italy a species, *P. italicus*, is found; and in Sardinia, Sicily, and Malta another species, *P. hispaniolus*, occurs, which in Spain breeds in the woods, while the common sparrow keeps to the towns. About 1862 the house sparrow was introduced into the United States, and it has also been acclimatised in Australia and New Zealand, in all which places it has become a great pest. The Tree-sparrow (*P. montanus*), the only other British species, is very similar to the common sparrow, but of rather smaller size; rarer and more local, but extending in its range, being found in the Hebrides and St Kilda, very sparingly in the south-west of England, and resident in Ireland near Dublin. It is multiplying in the Faeroes, and extends beyond the Arctic Circle. It is more abundant in some parts of Europe than the house-sparrow. It visits Egypt and Arabia, and is found in the south of Asia as far as the Philippine Islands and the Malay Peninsula. In Java a variety has developed (*P. malaccensis*). The White-throated Sparrow (*Zonotrichia albicollis*), an American form, is really a bunting. It has been found in the east of Scotland and the south of England. Other American sparrows have little in common with the genus *Passer*. The nostrils are in a small groove, and the tail is slightly forked.—The Hedge-sparrow (see WARBLER) is a bird belonging to an entirely different group; and the name sparrow is loosely given to various different birds in various parts of the world. For accounts of the destructiveness of the sparrow, see *The House Sparrow*, by J. H. Gurney, Russell, and Cones, and Miss Ormerod's Reports.

Sparrow-hawk (*Accipiter*), a genus of long-legged, short-winged falcons, nearly allied to and closely resembling the goshawks, but distinguished from them by their smaller size, weaker bill, and long, slender middle toe. The genus is represented in almost all parts of the world. The Common Sparrow-hawk (*A. nisus*), notwithstanding the constant war waged against it by gamekeepers, is still comparatively abundant in wooded districts throughout Great Britain and Ireland. It nests in trees, sometimes building a nest of its own, sometimes adopting one deserted by a crow or other bird. The eggs, four to six in number, are laid early in May, and are of a bluish-white colour marked with reddish brown. The food of the

sparrow-hawk ordinarily consists of small birds, which it takes while on the wing, but when rearing its brood it often commits great havoc among young game-birds and poultry. The adult male measures 13 inches, and has the upper parts of the body bluish gray, the under parts buff-coloured, with bright rufous bars. The female is paler in colouring and measures about 15 inches. The sparrow-hawk was used in falconry, but its feebleness

Common Sparrow-hawk (*Accipiter nisus*).

powers of flight made it of less value than the true falcons. It is bold and active, however, and is still often trained to take partridges and small birds; and it is recorded that a single trained sparrow-hawk took 327 birds in less than two months. The American Sparrow-hawk (*Falco sparverius*) is similar in size to the European, but is more nearly allied to the kestrel.

Sparta, anciently **LACEDÆMON**, the capital of Lacedæmon, and the most famous city of the Peloponnesus, situated on the right bank of the Eurotas, about 20 miles from the sea, in a plain shut in by mountains, of which that on the west side, Mount Taygetus, rises to a height of 8000 feet. The natural defences of the valley of Lacedæmon were so great that it continued unfortified down to the Macedonian period, and indeed was not regularly fortified till the time of the tyrant Nabis (195 B.C.). Previous to the Dorian conquest the primitive Achæans of Sparta seem to have dwelt in four or five scattered hamlets. Therapne, or Scrapna, on the other side of the river, seems to have been a Mycænean city destroyed by the Dorians. The hamlets in course of time, including ultimately Amyclæ, were grouped into one city by the conquerors, and became known as town-districts. Sparta's Acropolis was a steep hill in the northern part of the city, crowned with the temple of Athena *Poliouchos* or *Chalkioikos*. Here, as in all Dorian states, were found the three classes—*Helots*, or slaves; *Perioikoi*, freemen without political rights, dwelling in outlying towns; and the *Spartiates*, or the governing class of Dorians, with such others as had been admitted before a narrower policy was adopted. The foundation of Spartan greatness was attributed to the legislation of Lycurgus (q.v.). At the head of the government stood two *kings*, one of the family of the Agidæ, the other of the family of the Eurypontidæ, their royalty hereditary in the main line, but limited to sons born while the father was actually king. Their powers were equal, and

they were originally priests as well as judges and generals. After 506 B.C. only one king at once might take the field, and his powers came to be much curtailed by the growing power of the Ephors. These were five in number, elected annually by the people—the first giving his name to the year. Two accompanied the king on campaign, advising the three at home by the *εκνύδαι*, or secret despatches. They received foreign ambassadors, imposed taxes, and judged in all matters except those which specially belonged to the kings as priests. The standing council of kings and ephors was the *Gerousia*, consisting of twenty-eight Spartans above sixty, and elected from the chief families by the people. Once a month was held the *apella*, or assembly of all Spartans above thirty, who might vote but could not speak, which only the king, ephors, and members of the *gerousia* had the right to do. The Spartans never ceased to look upon themselves as merely a military garrison, and all their discipline pointed to war. No deformed child was allowed to be brought up; boys began to be drilled at seven, entered the ranks at twenty, and thereafter had to dine every day in one of the military messes (*ἀνδρεία* or *φιδίτρα*) in tents pitched in the public street. From twenty till sixty all Spartans were obliged to serve as Hoplites. In the 5th century the army was divided into twelve *lochoi*, commanded by *lochagoi*. Each *lochos* consisted of 500 men. After the Peloponnesian war the army was rearranged in six *morai*, each under a *potemarchos*. They never were strong at sea, although at Salamis they had ten ships, and under Lysander defeated the Athenian fleet and so ended the Peloponnesian war.

The earliest struggles of Sparta, after a shadowy war with Tegea (c. 800 B.C.), were with Messenia and Argos. The Messenian war, under king Theopompus, is said to have lasted twenty years (perhaps c. 736-16). A century later (c. 630) the enslaved Messenians revolted in vain. Similar struggles occurred both with the older Achæan inhabitants in the centre of Peloponnesus and with the Dorians of Argos, &c., in which the Spartans were for the most part successful. The Messenian revolt seems to be a turning-point. It was apparently soon after that the rigorous system, later connected with the name of Lycurgus, was set up. The arts had flourished down to the 7th century. From that time they were left to foreigners, and then allowed to die—though not at once, as the fine 5th-century statue discovered on the Acropolis in 1925 shows. Under their stern discipline the Spartans became a race of resolute, rude, and narrow-minded warriors, capable of a momentary self-sacrificing patriotism, as in the story of the 300 heroes who fell at Thermopylæ, but utterly destitute of the capacity for adopting or appreciating a permanently noble and wise policy. The outbreak of the Peloponnesian war (431 B.C.) brought the rivalry between Sparta and Athens to a head, and in the mighty struggle that ensued victory declared on the side of the combatant least capable of maintaining the greatness of Greece. Sparta now attained the hegemony of Greece; but her insolent tyranny in the hour of her triumph excited the indignation of those whom she held in virtual subjugation, and the glorious retaliations of the Thebans under Epaminondas stripped her of all her splendid acquisitions, and reduced the Lacedæmonian state to its primitive boundaries. Later the rise of the Macedonian power limited still more the Spartan territory, nor did it ever after attain its earlier dimensions. After a series of vicissitudes Sparta passed into the hands of the Romans, became a portion of the Roman province of Achaia, and finally shared the fortunes of the rest of Greece.

(q.v.). The growth of the town of Misthra, 2 miles SW. of Sparta, in the 14th and 15th centuries, led to the total desertion of the more ancient city; but the modern town of *Sparti* (pop. 6700), which was founded by the Greek government in 1836, occupies part of the site of old Sparta, and is again capital of the province of Laconia. The Sanctuary of the Brazen House on the Acropolis, the great theatre just below, and other sites have been excavated by the British School at Athens. See its publications for 1905-10, 1924 *et seq.* The German School has worked at Amyclae.

Spartacus, leader of the Roman slaves in the great revolt which broke out about 73 B.C., was a Thracian by birth, and from a shepherd had become a leader of a band of robbers when he was captured and sold to a trainer of gladiators at Capua. He formed a conspiracy to escape, and, when it was discovered, broke out with some seventy followers, with whom he made for the crater of Vesuvius, where hordes of runaway slaves soon joined him. He first overpowered and seized the arms of a force sent against him from Capua, next routed an army of 3000 men under C. Clodius, and so passed from victory to victory, overrunning Southern Italy and sacking many of the cities of Campania, his numbers growing to forty, seventy, and even a hundred thousand men. Great part of Central and Southern Italy had been thrown into pasture-land, on which the flocks belonging to rich absentee nobles were tended by gangs of discontented slaves, who flocked eagerly to the standard of revolt. Spartacus, who failed to get support from the Italian communities, and from the first knew the real weakness of his position, strove to persuade his victorious bands to march northwards to the Alps and disperse to their native regions; but they were intoxicated with victory, and saw glittering before their eyes all the plunder of Italy. Against his better judgment he continued the war, showing himself a consummate captain in the strategy and valour with which he routed one Roman consular army after another, and the policy by which for long he assuaged the jealousies and dissensions amongst his followers. At length in 71 M. Licinius Crassus received the command, and after some time of cautious delay forced Spartacus into the narrow peninsula of Ithegium, from which, however, he burst out through the Roman lines with a portion of his force. Crassus, in despair, urged the senate to recall Lucullus from Asia and Pompey from Spain, but meantime he himself pursued active hostilities against the dreaded enemy. Spartacus finding all hope at an end made a dash on Brundisium, hoping to seize the shipping and get across the Adriatic, but was foiled by the presence of Lucullus, whereupon he fell back upon the river Silarus, and there made a heroic stand against Crassus until he was cut down. In Germany the extreme Communist party, in insurrection in 1919 and 1920, took the name of Spartacists.

Spartanburg, capital of Spartanburg county, South Carolina, 93 miles by rail NNW. of Columbia. It has cotton-mills and other factories, and the Wofford (Methodist; 1853) College. Pop. 23,000.

Spasm (Gr. *spasma*) consists in an irregular and violent contraction of muscular parts—involuntary even when the voluntary muscles are concerned. There are two sorts of spasm. In one there is an unusually prolonged and strong muscular contraction, not rapidly alternating as usual with relaxation, the relaxation only taking place slowly, and after some time. This is known as *tonic spasm* (Gr. *tonos*, 'a bracing up') or *Cramp* (q.v.). When

in a more moderate degree affecting the voluntary muscles generally it constitutes *catatonía*, in which, from the muscles remaining contracted, the limbs will retain whatsoever attitude they are placed in, until the spasm is over. But the extreme example is *Tetanus* (q.v.), in which the spasms are so violent and so enduring that they profoundly exhaust the strength of the patient. In the other form of spasm the contractions of the affected muscles take place repeatedly, forcibly, and in quick succession; the relaxations being, of course, equally sudden and frequent. This is named *clonic spasm* (Gr. *klonos*, 'an agitation'), and is popularly known as *convulsions*. The spasmodic twitchings which sometimes occur in the muscles that close the eyelids (*orbicularis palpebrarum*) are familiar to almost everybody, and are an example of clonic spasm on a very small scale. Epilepsy and convulsive hysteria afford the best examples of this kind of spasm. Chorea (q.v.), or *St Vitus's dance*, is an allied but less regular and characteristic form.

The treatment varies according to the cause of the excessive muscular irritability. Firm pressure on muscles affected with spasm will promote their relaxation, and by strong steady pressure on the masseter muscles the lower jaw has been depressed, so as to open the mouth, in cases of lock-jaw. The medicines which are employed to counteract irregular or inordinate muscular action are termed *antispsmodics*; but spasm may depend upon so many different causes that the remedies which are found most successful in combating it must vary extremely in their nature. There are, however, a few medicines which appear to exercise a control over spasmodic action generally. These may be termed *pure* or *true* anti-spasmodics. They are various volatile oils, Asafoetida, Musk, and Valerian, and the Nitrites and Bromides. Amongst the narcotics often useful in these affections we may especially mention Belladonna, Cannabis Indica (or Indian hemp), Chloral, Opium, and Stramonium. Sulphuric ether in draught or inhaled, and inhaled chloroform, are often of service. In some cases, remedies which directly depress the vital powers, such as the prolonged use of the warm bath, or even, in rare cases, the abstraction of blood, are the most effectual means of subduing spasm.

Spasmodic School, a name applied to a group of English poets about the middle of the 19th century, among whom were Philip James Bailey, Sydney Dobell, and Alexander Smith. The name implied an overstrained and unnatural method of sentiment and expression, which sometimes grew out of sheer affectation and not seldom sank hopelessly into bathos. Professor Ayton's *Firmilian* (1854) was an excellent burlesque of the high-strung and grandiose style of these poets who took themselves much too seriously, and were for a moment also taken at their own valuation by the world.

Spathe (*Spatha*), in Botany, a sheathing bract which encloses one or more flowers, as in the Narcissus. Very frequently the flowers within a spathe are arranged upon a *spadix*, which is a succulent spike, with numerous flowers, and of which a familiar example may be seen in *Arum maculatum*. The spadix is a characteristic feature of the Palms, and in them is compound or branching, and in general is provided not only with a common spathe, but with secondary spathes at its divisions.

Spathic Iron Ore. See CHALYBITE.

Spavin. This term, when used without an adjective, indicates disease of the small bones of the hock, and its presence in any horse is regarded

as an unsoundness. It used to be comparatively common and was considered a very serious defect, so that to call a roadster a 'spavined nag' was about as bad a character as could be given. Fortunately, like many other hereditary ailments, it is not nearly so common as it was. It may occur in any form of hock, but short small hocks tied in below are very liable to it. A large broad flat hock is best. Allowing the hocks to grow long at the loes and using shoes with high toe-pieces are undoubtedly causes. The lameness may arise suddenly, but as a rule it is gradual in its appearance. It is most evident when the horse is coming out of the stable in the morning: he inclines to walk on his toe, but it tends to diminish on exercise. It is often very obvious in moving him across the stall—away from the lame leg. Frequently there is nothing local at first to indicate the seat of the lameness, but it usually results in an enlargement—the spavin—over the antero-internal aspect of the lower part of the hock, which can be seen and felt. If taken early in a young horse the removal of the shoe, trimming the hoof and shortening it round the toe, the application of a good snuit blister and three months at grass will sometimes arrest the mischief. But firing is often necessary, and is most effectual. In a horse past middle life a complete cure is seldom obtained, but an animal slightly lame from chronic spavin can often be utilised on the land when unfit to work on the road or street.

Speaker. See PARLIAMENT.

Speaking-trumpet. an instrument for enabling the sound of the human voice to be conveyed to a greater distance. It is of the utmost use on shipboard in enabling the officers to convey orders during windy weather from one part of the deck to another, or to the rigging. The invention is ascribed to Sir Samuel Morland, in 1670, though Athanasius Kircher laid claim to it. Morland's trumpet was of the same form as that now in use—viz. a truncated cone, with an outward curve or lip at the opening. The theory of the action of this instrument is much the same as that of the sounding-board of a musical instrument, but the sounding-board is aerial instead of solid. The air immediately in front of the instrument is acted upon over so wide a surface that it cannot effectively evade compression and rarefaction by any process of overflow and inflow towards the sides, and the result is as if the air were well laid hold of and firmly set in vibration.

Spear. a weapon of offence, consisting of a wooden shaft or pole varying in length up to 8 or 9 feet, and provided with a sharp piercing point. The spear may be regarded as the prototype of the various forms of piercing weapons, such as the arrow, bolt, and dart, which are projected from bows, catapults, or other engines, and the javelin, assegai, and lance, held in or thrown by the hand. The longer and heavier spears and lances are mainly retained in the hand while in use, but there is no absolute distinction, and the throwing of a spear has in all ages been a form of offensive warfare. In its earliest form the spear would naturally consist of a simple pole of tough wood sharpened to a point at one extremity, which point might be both formed and hardened by charring in fire. From this an improvement would consist in fitting to the shaft a separate spear-head of bone, as is still practised amongst primitive races. No trace of these early spears remains to us, but of the more developed forms having heads of chipmunk flint or other hard stones examples are plentiful, and most ingenious methods of fixing such heads are yet practised. To flint-heads succeeded heads of bronze (see BRONZE AGE), but these came

only late in the bronze period, and were still in use when the Homeric poems were composed. The bronze spear-heads found in Great Britain and in northern Europe generally were cast with sockets, into which the end of the shaft was inserted, but on the eastern Mediterranean coasts tanged spear-heads were used. These spear-heads were various in form and size, some being three-edged like the old bayonet, others with expanded leaf-shaped blades, some barbed, and some having loopholes either in socket or blade by which they were lashed to the shaft. The war-lance of the mediæval knights was 16 feet long; the weapon of modern cavalry regiments known as lancers may be from 8½ to 11 feet long, usually adorned with a small flag near the head. The Persians at the present day forge spear-heads, for ornamental purposes only, with two and sometimes three prongs. The modern spears of savage tribes, used equally for hunting and for warlike purposes, are frequently barbed with fish and other bones, and their fighting-spears have sometimes poisoned tips. Among the South Sea Islanders a fishing-spear having several slender barbed points is an important weapon. Among civilised communities the hunting-spear continues to be used for following the wild boar and other large game. See also PIKE, HALBERT, TRIDENT.

Species. This is a term which it is very difficult to define with precision. The word itself means a look, an appearance, a kind; and in common usage things that look the same are said to be of the same species. With more definiteness naturalists speak of a mineral species, and of a species of plants or animals. It is with this last usage that we are here concerned.

In classifying plants or animals we form conceptions of various degrees of comprehensiveness (see BIOLOGY), and for these we use a series of terms, such as class, order, family, genus, species, variety. The need for precision is that every one may know exactly what is meant when any individual or group of individuals is named. In the ordinary system of classification a species is a group of individuals which closely resemble one another, and the species is usually subordinated to a genus—a wider group of similar, but less closely similar, forms—and is superior to a variety, of which there may be several in a species. Thus we group the lions as a species (*Felis leo*) of the genus *Felis*, in the family *Felidae*, order *Carnivora*, class *Mammalia*, and call the tigers, leopards, cats, and the like other species of the same genus *Felis*. As no one could confuse lion, tiger, and leopard, for the peculiarities of each are well marked, it may be wondered what difficulty there is in defining species.

Let us consider the matter practically. We observe our fellow-men; we see that they differ in many ways from one another, in stature, in features, in complexion, in colour of eyes and hair, and so on; but we do not think of speaking of a red-haired or a blue-eyed species of man. We should as soon think of saying that the red-haired or blue-eyed child in a family was of a different species from its brothers and sisters or from its parents, which would be absurd. We must agree with the systematist when he says that the term species should not be given to a group of individuals which are distinguished from other groups by no greater differences than distinguish members of a family, and when he says that the characters of a species must have some constancy from genera-

tion to generation, which is not of course the case with red hair or blue eyes. This is a common-sense way of limiting the term, but it leaves many difficulties untouched. It is not readily applied to extinct species, of whose generations and individual variations we cannot know much; nor has it been applied to a vast number of forms recorded as species sometimes on the strength of single specimens, and often without any knowledge of their generations.

If we turn to the systematic treatises which classify plants and animals, and compare half a dozen of them, we find ample evidence of the elasticity of the conception of species. *Quot homines tot sententiae*. Thus, as Haeckel notices, one botanist enumerates 300 German species of the common Composite, *Hieracium*; another reduces them to 106, another to 52, another to about a score! Bechstein said that there were 367 species of birds in Germany, but according to Reichenbach there are 379, according to Meyer and Wolf 406, according to Pastor Brehm 900! But Haeckel himself supplies the best example, for in his important monograph on Calcareous Sponges he admits that as the naturalist likes to look at the problem there are 3 species, or 21, or 289, or 591! We are told that species are groups of individuals agreeing in essential characters which remain constant from generation to generation. But what are essential characters? and how much constancy is demonstrable?

The peculiarities on account of which a specific name is given to a group of individuals should not be of relatively trivial amount like the peculiarities which distinguish the brothers in a family; they should also show a fair amount of constancy from generation to generation; but there is another criterion of great importance. If two different forms when intercrossed have completely fertile offspring, it is unlikely that they were worthy of being distinguished as distinct species. For although there are cases of species—e.g. ducks—crossing and having fertile offspring, the general fact is interspecific sterility. This is in strong contrast to what holds true of most varieties, which may be crossed without diminution of fertility. It is a remarkable fact, showing how far biology still is from understanding the significance of species, that 'nothing readily comparable with the power to produce a sterile hybrid on crossing with a near ally, has yet been observed spontaneously arising, though that characteristic of specificity is one of the most widely distributed in nature' (Bateson, 1913). It may also be noted that more precise inquiry has demonstrated to an unexpected degree the detailedness and intricacy of specificity. There are minute chemical, histological, and physiological differences between nearly related species. The blood crystals of a dog are different from those of a fox; the wind-pipe cells of two allied forms are different in minutiae; two related species may be distinguished by the number and form of the chromosomes in the nuclei; the blood of one species may react differently from that of a neighbour species. There is extraordinarily subtle corroboration of the old statement: 'All flesh is not the same flesh; but there is one kind of flesh of men, another flesh of beasts, another of fishes, and another of birds.'

History.—In the second half of the 17th century John Ray began to be interested in the significance of species, pointing out, for instance, that varieties which can be produced from the seed of the same plant are to be regarded as belonging to the same species. Linnaeus invented the system of specific names (the 'binomial nomenclature'), and although he explicitly said that there were as many species as there were different forms created in the beginning ('species tot sunt diversae, quot diversas

formas ab initio creavit infinitum ens'), he also believed that diversity had arisen by the intermixing of an originally limited number of types, and that the species within a genus may have been one to start with ('ab initio unum constituerunt speciem'). The idea of the fixity of species which was largely taken for granted grew into a dogma (e.g. in Agassiz' *Essay on Classification*, 1859), which Darwinism disallowed, though more in theory than in zoological practice. It was important, however, that in Darwin's day variability was recognised as a fundamental fact of life, and that the problem of the origin of species, still in essence unsolved, came to be regarded as open to scientific investigation and experiment. The limitations of the general Darwinian view were (1) that species were regarded as merely impermanent groups, each of which possessed a congeries of adaptive characters fitted to particular conditions of life (whereas we know of many specific characters which have not been shown to be of the nature of adaptations); and (2) that species were supposed to arise from other species by the transformation of large numbers by very gradual steps under the influence of natural selection (a theory which must be modified in the light of what is now known in regard to the frequent occurrence of discontinuous variations or mutations). From the dogma of the fixity of species the pendulum swung to an equally extreme view of their fluidity and of their linkage by intermediate gradations to other species. In the 20th century investigation has turned again to the stability and discontinuity of species, the general fact of interspecific sterility, and the non-utilitarian character of many specific characters.

See BIOLOGY, BOTANY, DARWINIAN THEORY, EVOLUTION, GENES, HEREDITY, VARIATION, ZOOLOGY. See also Darwin, *Origin of Species* (1859); Haeckel, *Generelle Morphologie* (1866) and *Natural History of Creation* (1873); Spencer, *Principles of Biology* (1864-66); Wallace, *Darwinism* (1889); De Vries, *Species and Varieties* (1905); Bateson, *Materials for the Study of Variation* (1894); and *Problems of Genetics* (1913).—The species of Logic is originally suggested by Natural Species, and may be defined as a group of individuals agreeing in some common character and known by a common name; two or more species constituting a genus. The relation of species to the other logical elements of classification are treated at PREDICABLES and GENERALISATION. The great controversies as to the real existence of species and other universals are sketched at NOMINALISM.

Specific Density, the mass of any given substance contained in unit volume. On the centimetre-gramme-second system of physical units, since a cubic centimetre of water at standard temperature and pressure weighs 1 gramme, the density of water = 1, and water is the standard of density; and the specific density of a body is the number of grammes' mass per cubic centimetre. Since, according to the law of gravity, weights are proportional to masses, it is convenient to ascertain specific densities by ascertaining the specific gravities of the substances tested. For example, an English gallon of water weighs at standard temperature and pressure (62° F. and barometer 30 inches) 10 lb. avoirdupois; a gallon of ether weighs 7.2 lb.; the specific density of ether is therefore $7.2 \div 10 = 0.72$. Similarly, a gallon of strong sulphuric acid weighs 18.4 lb., and the specific density of sulphuric acid is 1.84. The specific densities of solids may be determined by the hydrostatic balance (see ARCHIMEDES, PRINCIPLE OF), which gives the weight of a quantity of water equal to that of the solid; or by using a 'specific gravity flask.' This is a flask marked distinctively at a certain level; the solid is put into this; the flask is filled with water up to the

mark, and weighed; the whole is then emptied and filled with water alone up to the mark, and again weighed. The two weighings give the data for ascertaining the ratio between the weight of the solid and that of an equal bulk of water. If the solid is acted upon by water, some other liquid of known specific density must be employed, and the calculation varied accordingly. If it be lighter than water, it is coupled with a piece of heavy substance whose weight and specific density are separately known, and the aggregate apparent loss of weight incurred by the combination on being immersed in liquid is found by the hydrostatic balance. Of this aggregate so much is due to the heavy substance and the remainder to the light solid. This gives data for calculating the specific density of the light solid. The specific density of a liquid is ascertained by simply comparing the weights of quantities of that liquid and of water successively made to fill the specific gravity flask up to the same marked level; or by comparing the apparent losses of weight incurred by a solid on being immersed in water and in the liquid respectively; or by the use of hydrometers or areometers. The areometer (*araos*), 'thin,' and *metro*, 'I measure'; Fr. *aréomètre* or *pèse-liquore*; Ger. *Aräometer* or *Senkwaage*) or hydrometer is a graduated instrument which floats in a liquid, without being wholly submerged, under the equilibrium of the weight of the whole body acting downwards, and the buoyancy of the liquid, equal to the weight of the part of the liquid displaced, and acting upwards. The specific density of a uniform cylinder, say of ice, floating vertically in water is the volume immersed \div the whole volume; and in liquids of different specific densities such cylinders would sink to different depths. But it is more convenient to use graduated hollow glass instruments weighted with mercury at one end to make them float vertically (see fig. 1). AB is graduated; C is a large bulb; D is a small bulb containing mercury, the quantity of which is so adjusted that the instrument sinks in water, say to the point W. If the liquid be heavier than water the instrument will not sink so far; the position of equilibrium in which the weight of the whole instrument is equal to the weight of the liquid displaced will be sooner reached; and, conversely, if the liquid be lighter than water the instrument will sink farther. Each instrument must be experimentally graduated by placing it in liquids of known specific densities. By varying the adjustment of the mercury a series of instruments may be made, serviceable in ascertaining the specific densities of liquids within particular ranges of density—e.g. instruments for sulphuric acid, milk, alcohol, &c. The delicacy of such an instrument depends on the bulb C being large and the stem AB thin. The chief modes of graduation are (1) Gay-Lussac's areometer or volumometer. In water the instrument

Fig. 1. stands at 100°. All the degrees are equal, and each = $\frac{1}{100}$ the volume of that part of the instrument which is immersed when it floats in water. If n be the numerical reading when the instrument is floated in a given liquid, the specific density of that liquid is $100 \div n$ —e.g. if the instrument stand at 80°, the specific density = $100/80 = 1.25$. (2) Baumé, for liquids heavier than water. Water at 17.5° C. = 0°; an aqueous solution containing 10 per cent. by weight of common salt (NaCl) at 17.5° C. = 10°; the scale is uniformly graduated; specific density = $146.8 \div (146.8 - n)$. (3) Baumé, for liquids lighter than water; 10 per cent. by weight salt-solution at 12.5° C. = 0°; water at 12.5° C. = 10°; specific density = $146 \div (136 +$

$n)$. (4) 'Rational' Baumé, for liquids heavier than water; water at 15° C. = 0°; sulphuric acid, specific density = 1.842 = 66°; specific density = $144.3 \div (144.3 - n)$. (5) Cartier, resembles Baumé; for liquids lighter than water, 21° Cartier = 21° Baumé; otherwise 15 Cartier degrees = 16 Baumé degrees; specific density = $136.8 \div (126.1 \mp n)$. (6) Deck; pure water = 0°; specific density, 0.850 = -30°; uniform graduation; specific density = $170 \div (170 \mp n)$. (7) Twaddell, most used in England; water = 0°; graduation not uniform, but readings direct; specific density = $(1000 + 5n) \div 1000$ —e.g. a gallon of acid of 24° Twaddell weighs 10 lb. $\times \frac{1000 + 120}{1000} = 10$ lb. $\times 1.12 = 11.2$ lb. (8) Tralles,

an alcoholometer scale used on the Continent, adjusted so as to show directly the volume-percentage of alcohol in alcohol and water. (9) Sikes, used in the British Customs and Excise; graduated so as to show how many volumes of water must be added to or taken from 100 volumes of the mixture under examination to reduce it to proof-spirit (a mixture whose density = $\frac{1}{2}$ that of water at 51° F.—i.e. 57.09° Tralles), the instrument being adjustable to different ranges of density by a set of movable weights. Instead of making the quantity of liquid displaced to vary, as in the above instruments, the displacement may be kept constant and the weight of the instrument varied. Fig. 2 shows Nicholson's areometer—a hollow

Fig. 2.

brass case, BC; cups at A and D; a weight at E. Suppose it weighs 2000 grains; and let it sink in water to a certain mark between B and A when 500 grains weight is put in A. If it be now transferred to another liquid in which only 250 grains are required to make it sink to the same mark, the second liquid is lighter than water in the ratio of 2250, the whole weight of the apparatus, to 2500, its former whole weight; and its specific density is therefore $\frac{2250}{2500} = 0.9$. The same instrument may be used to find the specific density of small solids thus: put a little stone or gem in A; to make the apparatus sink to the mark say 440 grains are required; therefore the stone weighs 60 grains. Now put it in D. More weights, say 20 grains, must now be put in A; the 20 grains represent the apparent loss of weight in water; the specific density = weight in air \div apparent loss in water = $60/20 = 3$. By reversing D, which is perforated, the specific density of bodies lighter than water may be ascertained. Fahrenheit's areometer, the original form, differs from Nicholson's in having no platform or cup D. Rousseau's densimeter combines the two methods described above. It bears a cup or cavity at its summit. This is filled successively with various liquids; each induces a different amount of sinking. The instrument-maker has to do the preliminary graduation by the use of known liquids. Specific-gravity bulbs are also used; they are marked with numbers representing specific densities. Those which are too heavy sink; those which are too light float; the one exactly corresponding to the density of the liquid, if there be one, neither rises nor sinks. The most accurate method is that by the specific gravity flask. The specific density of a gas or vapour is determined (1) by weighing a copper flask when empty, when filled with the gas, and when filled with air, which method gives the density of the gas relatively to that of air, when proper corrections are made so as to compare the two gases at the same temperature and pressure; (2) by ascertaining the volume occupied by a given weight of the gas or vapour at a

known temperature and pressure; (3) by measuring the weight of vapour which can occupy a known volume, this being effected by putting liquid into a vessel of known capacity and heating until there is, at a known temperature and the atmospheric pressure, nothing but vapour in the vessel, then closing and weighing when cool. The last two methods are specially applicable to vapours rather than to permanent gases. It is often convenient, instead of taking the true specific density of a gas or vapour—e.g. that of air, the number of grammes per cubic centimetre of which is 0.0012932—to state its density as compared with air or hydrogen as a standard. In this way air is said to have a density = 1 or = 14.47, according as air or hydrogen is taken as the standard. The use of hydrogen as a standard is of special convenience in chemical calculations, for the densities of gases or vapours so measured are, as a rule, proportional to their molecular weights. The following are the specific densities of some common substances:

Air.....	0.0012932	Hydrochloric acid solution at 32° F.....	0.908
Alcohol.....	0.80	Hydrocyanic acid gas (= 0.9476 x air).....	0.001225
Aluminium.....	2.56 to 2.67	Hydrogen (= 0.000926 x air).....	0.00008958
Auriferous gas (= 0.589 x air).....	0.000762	Ice.....	0.91674
Ammonia solution.....	0.88	Iridium.....	22.42
Amorphous arsenic.....	4.71	Ivory.....	1.8 to 1.9
Anthracite.....	1.4 to 1.7	Lead.....	11.37
Antimony.....	6.75	Lignum-vitæ.....	1.33
Arsenic crystals.....	5.13	Limestone.....	2.6 to 2.8
Ash.....	0.84	Liquefied oxygen.....	1.124
Bismuth.....	9.9	Lithium.....	0.5936
Blood.....	1.04	Leadstone.....	4.9 to 5.2
Bone.....	1.6 to 1.9	Manganese.....	7.2
Brown coal.....	1.2 to 1.4	Marble.....	2.5 to 2.8
Butter.....	0.94	Mercury.....	13.60
Calcium.....	1.578	Milk.....	1.03
Cannel coal.....	1.16 to 1.27	Nitre acid.....	1.517
Carbonic acid gas (= 1.524 x air).....	0.00197	Nitrogen (0.9713 x air).....	0.00126
Cast-iron.....	7 to 7.6	Oak, English.....	0.97
Chalk.....	2.45	Oil of cloves.....	1.03
Charcoal.....	0.3 to 0.5	Oil of turpentine.....	0.87
Chlorine (2.4602 x air).....	0.00317	Olefin gas (= 0.9784 x air).....	0.001365
Chry.....	1.8 to 2.5	Oxygen (= 1.1056 x air).....	0.00143
Coalbit.....	8.95	Platinum.....	21.1 to 21.7
Copper.....	8.96 to 8.94	Poplar.....	0.38
Cork.....	0.24	Potassium.....	0.86
Cyanogen (1.806 x air).....	0.00234	Ruby.....	4.3
Diamond.....	3.53 to 3.55	Sand in bulk, dry, about.....	1.3 to 2.0
Dry yeast.....	0.5	" " wet.....	1.3 to 2.0
Elin.....	0.67	Silver.....	10.53
Flint.....	2.6 to 2.7	Sodium.....	0.972
Glass.....	2.4 to 3.6	Spanish mahogany.....	1.06
Gold.....	19.26 to 19.35	Steel.....	7.6 to 7.8
Granite.....	2.5 to 2.9	Sulphuric acid.....	1.854
Honey.....	1.45	Sulphuric ether.....	0.72
Human body alive.....	0.80	Sulphurous acid gas (= 2.24 x air).....	0.0029
Hydrolic acid (= 4.44 times that of air or 61.11 times that of hydrogen).....	0.00574	Tin.....	7.29
Hydrochloric acid gas (= 1.26 x air).....	0.00168	Topaz.....	3.4 to 3.6
		Wrought-iron.....	7.25 to 7.79
		Zinc.....	0.86 to 7.21

Specific Gravity. the weight of any given substance as compared with the weight of an equal bulk or volume of water or other standard substance at the same temperature and pressure. See SPECIFIC DENSITY.

Spectacles. for the purpose of aiding the sight when impaired by age or otherwise (see EYE), are commonly said to have been invented during the 13th century. The merit is variously attributed to Alessandro di Spina, a monk who died at Pisa in 1313, and to Salvo degli Amati, who died at Florence in 1317; but spectacles seem to be referred to by the Arab writer Alhazzen (11th century) and by Roger Bacon (c. 1214-94). In 1482 there were spectacle-makers at Nürnberg. At first spectacles were exceedingly clumsy, both in the lenses themselves and also in their frames; and very little improvement took place in them until the beginning of the 18th century, when light metal frames were introduced instead of the cumbersome horn mountings.

Until comparatively recently the progress made in regard to the production of ophthalmic lenses was wholly restricted to mechanical perfection, to external finish, and to careful selection of the finished product. Scientific progress, on the other hand, in regard to the construction of lenses, to their curvature and to their usefulness from a sight-correcting point of view, was entirely neglected, so that for almost a hundred years ophthalmic lenses were ground to the same general principles. This is all the more remarkable, as during this very period far-reaching inventions of much more complicated optical systems—microscopes, telescopes, prism field-glasses, range-finders, &c.—were made. But only in the beginning of this century were new ideas advanced upon the construction of ophthalmic lenses, which are admitted to be vastly superior to those previously employed. Deep-curved or toric lenses, both for spherical and astigmatic corrections, greatly widen the field of vision. This obviously is a great advantage, not only for general wear, but in those occupations such as accountancy, typing, drawing, and the many other spheres of work where the eyes have to keep moving about in various directions.

Continental firms took a foremost part in the introduction of perfectly homogeneous clear optical glass, and thus secured a large volume of the trade, but when the Great War broke out all such supplies were cut off. The United States at once seized the opportunity of filling the market and introducing its specialities in lenses and frames, many of which have retained their popularity. The British government, realising the absolute necessity of maintaining the production of optical instruments at least equal to those of the enemy, subsidised firms in Britain to manufacture optical glass under the best scientists and investigators, such as Sir William Crookes, with such success that Britain became entirely independent of foreign competition. Non-actinic glass, which, while allowing all the illuminating rays of the spectrum to pass to the eye, cuts off the injurious infra-red and ultra-violet, is in general use for users in bright light.

There are at present in vogue a large variety of spectacle and eyeglass mountings—rusted steel, dainty rimless, solid gold, beautiful tortoise-shell, rolled gold, and imitations in the various patterns—a preference being given to large lenses, round or oval.

Much more attention is now paid to the correction of defective sight. School-children are examined by medical specialists. Opticians have undergone an exhaustive training and qualified themselves to undertake refraction corrective work as distinct from the treatment of disease. See EYE.

Spectrum. As explained under the article COLOUR, light emanating from any ordinary source is rarely if ever homogeneous. It is composed of rays of different wave-lengths, each of which if viewed singly would appear to have an appropriate colour. The general colour-sensation produced by such a heterogeneous ray can teach us very little concerning its composition. Not until we have formed its spectrum by appropriate means are we able to analyse it. A spectrum is in fact an image in which the component parts of a given ray of light are separated from one another so that each may be viewed singly.

Newton was the first who scientifically produced and studied the spectrum of sunlight. This he did by interposing a glass prism in the path of a ray which was allowed to enter a dark room through a small hole in the shutter. The arrangement is shown diagrammatically in fig. 1. Here the rays are bent out of their original course, SA, as they pass through the prism P; and on the screen, H, the

spectrum of colours is formed instead of the image A. Newton regarded the spectrum as being divisible into seven differently coloured spaces, which he called in order red, orange, yellow, green, blue, indigo, and violet. It is impossible, however, to settle precisely the exact boundary between any two of these fancied species of colour, which pass by insensible gradations one into another. As Newton clearly demonstrated, the spectrum is produced because the differently coloured constituents of sunlight have different refrangibilities, the red being refracted least of all and the violet greatest of all (see REFRACTION). If light of a particular refrangibility were absent or of less intensity than the other constituents gaps would appear in the spectrum. As a matter of fact such gaps do exist in the solar spectrum, and were first observed by Wollaston in 1802. In 1817 Fraunhofer, with much more perfect optical apparatus, measured the relative positions of a great number of these *dark lines*, and named the more important of them by the early letters of the alphabet. These are shown in

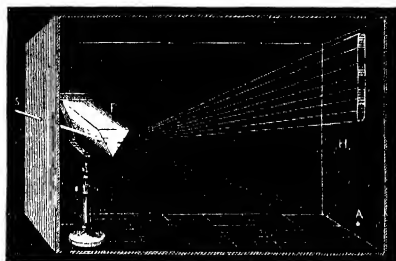

Fig. 1.

the first spectrum in the table of spectra. They are the standard lines with which it is usual to compare the lines characteristic of other spectra.

For the careful observation of these lines the spectroscope or spectrometer has been constructed. It consists essentially of a prism or train of prisms, P; a collimator, C, at the focus of whose lens, L, is placed a narrow slit, S, parallel to the edge of the prism; and a telescope, T, for producing a magnified image of the spectrum of the illuminated slit. Nearly all transparent refractory substances give similar spectra, although the dark lines may be somewhat differently spaced in the different cases. This arises from the fact that substances vary in

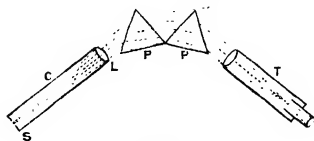

Fig. 2.

their dispersive as well as in their refractive powers (see DISPERSION). The optical value of the spectroscope is that it gives us the means of accurately determining the refractive indices of different substances for rays of definite wave-lengths. Now, although refrangibility depends on wave-length, being in general greater for the shorter wave, it does not depend upon it according to any simple or common law. Hence in prismatic spectra the characteristic lines are not spaced in accordance with any simple relation to the wave-lengths of the corresponding rays. If, however, we substitute for the

prismatic part of the spectroscope a diffraction-grating, we obtain a spectrum in which the rays are spaced according to a law of extreme simplicity.

A diffraction-grating is formed by ruling a series of fine lines on a glass or metal surface. For the production of a good spectrum it is necessary that the lines should be equidistant and so close that several thousands go to an inch. If the image of an illuminated slit be viewed by a telescope through or after reflection from such a grating, a remarkable appearance is presented. A central luminous line is seen, just as if no grating existed, and for some distance on either side the field is dark. But soon on both sides spectra appear, with their blue ends nearest the central line. Still farther to left and right secondary spectra appear, their blue ends overlapping the red ends of the primary spectra. These are followed by a third but fainter set, and so on. These successive spectra are due to the interference (q.v.) of the rays emanating from the discontinuous wave-front which has been made so discontinuous at the grating. The absolute position and breadth of the spectra depend on the closeness of the lines of the grating; but the relative positions of the coloured rays in any spectrum depend only on the wave-lengths.

Thus in the solar spectrum produced by a diffraction-grating Fraunhofer's lines are so distributed that their distances from the central luminous line above mentioned are proportional to the wave-lengths of the corresponding rays of light. This spectrum is accordingly called the Normal Spectrum. Compared with it, the ordinary prismatic spectrum is much crushed towards the red end and extended towards the violet end. A rough comparison is shown in fig. 3, the principal Fraunhofer lines being given in the two spectra, which are of the same total length.

Professor Rowland, by means of his concave gratings, or gratings marked on a concave cylindrical surface of speculum metal, produced remarkably fine spectra. Because of the slight concavity the grating focuses the spectrum clearly at a particular distance, so that the object glass of the telescope may be dispensed with.

We have now to consider the significance of the dark lines in the solar spectrum. These gaps may be imagined as originating in two ways. They may be absent in the sunlight from the very beginning, or they may be absorbed by some substance through which the ray passes from the sun to the earth. As Brewster showed long ago, many of the lines are really due to absorption by the earth's atmosphere, and are more marked when the sun is low than when the sun is high. These lines which are certainly due to absorption by the earth's atmosphere are called telluric. Near the Fraunhofer D lines there exists a very remarkable group of lines known as the Rain-band. It is due to water-vapour in the air, and gets very dark as

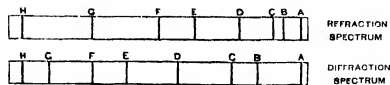

Fig. 3.

the humidity approaches saturation. The principal lines in the solar spectrum are, however, not telluric. Nor can they be explained as due to the absorptive action of the ether, inasmuch as the various spectra of stars, though broadly similar to that of the sun, differ from it and from one another greatly in detail. (Compare, for example, the spectra of Sirius and of the sun in the table.)

In short, solar and stellar spectra are very characteristic in the number and distribution of the lines which cross what is otherwise a continuous spectrum (see STARS). If then these lines are due to absorption, it must be absorption in the atmosphere enveloping each star or sun. That this is the true explanation of the dark lines has been for long regarded as established beyond a doubt.

Previous, however, to the discovery of the principle which lies at the basis of stellar and solar spectroscopy, the great variety of spectra given by different substances had been recognised. Some of these are shown in the accompanying table of spectra; and, as suggested by Talbot and Herschel in 1825, an obvious application of the prism is to the qualitative determination of small quantities of substances in minerals. In the accompanying coloured plate, the characteristic spectra of the vapours of some of the metals taken by themselves may be compared with the very different spectra of the sun, of nitric peroxide, and of Sirius; that of the nebula in Orion almost rivals in simplicity the visible spectrum of sodium vapour. The case of Thallium (q.v.) is of peculiar historic interest, since it was the observation of its very characteristic line spectrum which led to its discovery. Of even greater interest historically is the spectrum of sodium, which may be observed by burning common salt in a spirit-flame. Fraunhofer observed that the two bright yellow lines so characteristic of the sodium spectrum coincided in position with the double line known as D in the solar spectrum. A very careful test of this coincidence was made by Professor Miller, following upon which Stokes (in 1850) gave for the first time the physical explanation of the phenomenon—viz. that the Fraunhofer double D is produced by the absorptive action of sodium vapour in the sun's atmosphere. Foucault (in 1849) had already obtained an evident darkening of the D lines when the ray of sunlight was passed through the electric arc, which gave in its spectrum the bright sodium lines; but he failed to grasp the significance of the experiment. Ten years later Kirchhoff made a similar experiment, and to him we owe the complete statement of the principle on which spectrum analysis is based. (For the important work of Balfour Stewart in this connection, see HEAT.) The principle is defined by Kirchhoff thus: the ratio of the emissive and absorptive powers for any given radiation is the same for all bodies at the same temperature. If we imagine the existence of an ideal *black body* which is at once a perfect absorber and a perfect radiator, we may, following Tait in his development of Stewart, express the principle in this wise: for any given temperature the emissivity of a radiating body is equal to its absorptivity. Here emissivity is the emissive power of the chosen body compared with that of the ideal black body; and similarly absorptivity is the ratio of the absorptive powers of the chosen body and the black body for the same radiation at the same temperature. Suppose we have a body A exposed to radiation r from a body B. If A were black the whole radiation would be absorbed. As it is, however, the body A will absorb only er , where e is the emissivity. Again, if R is the measure of the radiation which a black body at the temperature of A would radiate, er will measure the radiation of A. Hence the amount of radiation which reaches us from A, and through A from B, will be $er + (r - er) = r - e(r - R)$. Hence there will be a real resultant absorption by A as the rays from B pass through it if, and only if, r is greater than R —i.e. in accordance with experience, if B is at a higher temperature than A. The ultimate basis of the argument is the Second Law of Thermodynamics (q.v.); and it should be noted that

the principle fails to apply to cases of phosphorescence or fluorescence. Thus we conclude that the Fraunhofer lines in the solar spectrum are due to the absorptive action of the comparatively cool atmosphere of the sun upon the radiation which comes from the hotter interior parts. At the instant of a total eclipse of the sun, when the hot interior is screened off, the spectrum of the cooler but still self-luminous envelope is seen to consist of several bright lines. With the exception of one peculiar line in the yellow, these are all coincident in position with certain of the dark Fraunhofer lines. The most conspicuous of the lines that so become reversed are the four hydrogen lines. The b line due to magnesium, the double D, and some of the iron lines have also been observed reversed at the instant of totality.

The identification of the dark lines in solar and stellar spectra with the bright lines in the spectra of the various elementary substances raised to a high enough temperature is one of the most important labours of the spectroscopist. A list of the elements which have been proved to exist in the solar atmosphere will be found in the article SUN. In fig. 4 a small portion of the sun's spectrum near the

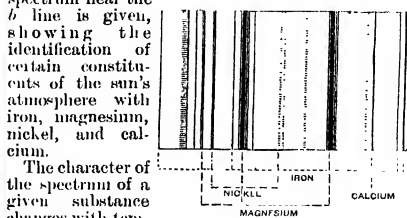

Fig. 4.

The character of the spectrum of a given substance changes with temperature and pressure. For example, although hydrogen, like all gases, gives at ordinary pressures a bright line spectrum with sharp thin lines, these lines become broader and broader as the pressure is increased, until at very high pressures the spectrum becomes almost continuous like that given by a glowing white hot solid. Thus we learn that a highly compressed gas at a high temperature ceases to give the discontinuous bright line spectrum so characteristic of it at low pressures. One tolerably safe conclusion to draw is that stars which all have continuous spectra crossed by dark absorption lines or bands consist of a highly condensed nucleus; whereas true nebulae, which show bright line spectra (see the table of spectra), are luminous because of the presence of glowing gas in a comparatively attenuated condition. In the case of Comets (q.v.) the spectrum is faintly continuous with bright lines crossing it—a mingling of solar reflected light with the proper gaseous spectrum of the comet itself. The planets give in like manner the spectrum of sunlight modified more or less by the absorptive character of their atmospheres.

If a ray of sunlight, or a ray from the electric or lime light, is passed through various liquids, very characteristic absorption bands are obtained across the otherwise continuous spectrum. For example, arterial and venous bloods give absorption spectra, which are readily distinguishable one from the other. The second spectrum in the plate is an absorption spectrum produced by passing the electric ray through peroxide of nitrogen. It shows the banded characteristics of such spectra.

A very remarkable application of spectrum analysis is to the measurement of the rate of approach or recession of any heavenly body. If we are approaching a star the waves of light will

meet us at a somewhat quicker rate than if we were relatively steady with regard to it. That is, the waves of light will appear to be shorter—hence all the lines in the spectrum will be displaced towards the violet end. On the other hand, if we are receding from the star, the spectrum lines will appear to be shifted towards the red end. For example, in the spectrum of Sirius, the F line is very slightly shifted towards the red by an amount which is measurable in a fine spectroscopic. The interpretation is that Sirius is receding from the solar system with a velocity of about 20 miles per second. Arcturus, on the other hand, is approaching our system with a speed of 55 miles per second. Similar displacements of lines are observed in the spectra of certain sun-spots, which are thereby proved to consist of downrushes of gas.

Throughout this article we have confined our attention to the *visible* part of solar spectrum. But this extends much further than is apparent to the eye. Below the red are the dark heat rays, whose presence or absence can be demonstrated by the appropriate means. Professor Langley has specially studied this region with the aid of rock-salt prisms and the Bolometer (q.v.), and has carefully measured the positions of the absorption bands. Captain Abney has, by use of a special preparation of bromide of silver, obtained photographs of the infra-red end of the spectrum, and has identified some of the absorption lines with lines in the spectra of metals of low melting points, such as sodium and calcium. Metals which volatilise at high temperatures do not seem to give lines below the red. Above the visible violet again are the invisible actinic rays. This upper part of the spectrum can be made visible by allowing it to fall upon some suitable fluorescent substance, such as uranium glass or a solution of sulphate of quinine. Photography, however, supplies us with a perfect method for obtaining visible images of the actinic spectrum. Indeed, by properly choosing the sensitive substance, we can now photograph any part of the spectrum from a radiation of nearly four times the wave-length of the red rays up to the highest actinic rays known to exist; and in the extended solar spectrum so obtained we find the same characteristics throughout—a continuous spectrum crossed by dark lines.

Of recent years great progress has been made in investigation of the optical spectrum (including the invisible neighbouring infra-red and ultra-violet), with the aid of diffraction gratings and optical appliances of high resolving power. It was known that in addition to bright lines there were in many instances bright bands which, as the density of the gas increased, broadened and seemed to merge in one another, producing a quasi-continuous spectrum, generally of a channelled or fluted appearance. Now these bright bands have been resolved into multitudes of bright lines crowding up to a limiting line or head, and reason has been shown for believing that they are due to undissociated molecules. The lines of a line spectrum (which have proved to be much more numerous and often much less simple than those shown in the coloured table of spectra) are due to the atoms themselves; when produced by a Bunsen flame or an electric arc they appear to be associated with removal of one electron from a neutral atom; when produced by the more violent action of an electric spark we have a spark spectrum, containing additional lines and apparently associated with the removal of a second electron. Now on registering and comparing the wave-lengths of the different bright lines in a line spectrum it is found (not without painstaking labour) that the whole system of bright lines can be unravelled into systematic series (generally four in number,

usually overlapping one another and differing from one another in appearance and in their behaviour, e.g., under absorption) of lines. The relations between the wave-lengths in each series and the relations between the different series are found to be expressible by comparatively simple mathematical formulae; and reasoning upon these formulae has thrown much light upon the structure of the atom. See Andradé's *Structure of the Atom* (1923).

Invisible spectra have been formed (compare CRYSTALLOGRAPHY, pp. 601-2) by X-ray radiations emitted by different substances. As X-ray radiation is an affair of the atom alone, not of the molecule, and indeed seems to depend only on the inner electrons of the atom, it follows that the X-ray spectrum is much simpler than the optical spectrum; there are no bands, due to molecules; there are usually three series of lines, and these do not overlap one another. The comparative simplicity of the X-ray spectrum renders it of great service in investigating the structure of the atom with the aid of Einstein-theory and Quantum (q.v.) conceptions (see Andradé, *op. cit.*).

See Schellen, *Spectralanalyse* (trans. 1885); Loekyer, *Spectrum Analysis* (2d ed. 1886); Landauer, *Spectrum Analysis* (New York, 1897); Kayser, *Spektroskopie* (1900); Marshall Watts, *Spectrum Analysis* (1904).

Specular Iron. See HAEMATITE.

Speculum Metal, an alloy used for the specula or mirrors of reflecting telescopes. The best is composed of 126 parts of copper and 58.9 of tin. It takes a fine polish and is not easily tarnished unless exposed to damp. Glass with a film of metallic silver deposited upon it is now taking the place of speculum metal for these mirrors. The silvered glass is equally serviceable and less costly. See TELESCOPE.

Spedding, JAMES, was born at Mirehouse, near Bassenthwaite, 26th June 1808, the younger son of a Cumberland squire. From Bury St Edmunds, where he was head of the school, he proceeded in 1827 to Trinity College, Cambridge, of which he became a scholar, and of which too at his death he had long been an honorary fellow. Still, brilliant scholar though he was, his degree was only a second-class in classics and junior optime. From 1835 to 1841 he held a post at the Colonial Office; in 1842 he accompanied Lord Ashlinston (q.v.) to America as private secretary; and in 1847 he might, had he chosen, have become Under-secretary of State, with £2000 a year. But he had already devoted himself to the task of his life—'to re-edit Bacon's Works, which did not want any such re-edition, and to vindicate his character, which could not be vindicated.' So writes Edward Fitzgerald, the oldest of Spedding's many brilliant friends—Tennyson and Carlyle were also of the number—and he adds: 'He was the wisest man I have known; not the less so for plenty of the boy in him; a great sense of humour; a Socrates in life and death, which he faced with all serenity so long as consciousness lasted.' That death was in St George's Hospital, on 9th March 1881, Spedding having eight days before been run over by a cab.

His publications were *Works, Life, and Letters of Bacon* (14 vols. 1857-74); *Publishers and Authors* (1867); *Account of the Life and Times of Bacon* (2 vols. 1878); *Reviews and Discussions not relating to Bacon* (1879); *Studies in English History* (1881), in conjunction with J. Gairdner; and *Evenings with a Reviewer* (relating to Bacon, 2 vols. 1881). See the brief Memoir by G. S. Venables prefixed to the last, and also Fitzgerald's *Letters* (1889).

Speech. See ADAM, DEAF AND DUMB, DUMBNESS, LINGUISTICS, PHILOLOGY, PHONETICS, VISIBLE SPEECH, VOICE.

Speed, JOHN, antiquary, was born at Farrington in Cheshire in 1542, worked most of his days at London as a tailor, and died 28th July 1629, being buried in St Giles's, Cripplegate. All his life long he had been acquiring historical learning, and his extraordinary attainments at length gained him the acquaintance of Sir Fulke Greville and others, and hence opened up a door for the publication of the great works through which his name survives. These are *Maps* (54) of *England and Wales* (1608 10; incorporated into *The Theatre of the Empire of Great Britain*, 1611); *The History of Great Britain under the Conquests of the Romans, Saxons, Danes, and Normans* (1611). His theological writings are of no importance.

Speedwell (*Veronica*), a genus of plants of the family Scrophulariaceae, distinguished by a four-cleft wheel-shaped corolla, with the lower segment narrower, two stamens, and a two-celled capsule. The species are very numerous, annual and perennial herbaceous plants and small shrubs, natives of temperate and cold climates in all parts of the globe. Some of them grow in wet ditches and in marshes, some only on the driest soils. They have generally very beautiful blue, white, or pink flowers. The number of British species is

Common Speedwell
(*Veronica officinalis*).

considerable, and few wild-flowers are more beautiful than the German Speedwell (*V. Chamaedrys*), or the alpine species, *V. alpina* and *V. saxatilis*. A number of species are very generally cultivated in flower-gardens. The bitter and astringent leaves of the Common Speedwell (*V. officinalis*), one of the most abundant British species, found also in almost all the northern parts of the world, are in some countries used as a tonic, sudorific, diuretic, and expectorant medicine. They are also employed as a substitute for tea, as are those of the German Speedwell. *V. virginica* is called *Culver's Physic* in North America; it is said to be actively diuretic, and a decoction of the fresh root is violently cathartic and emetic. Brooklime (*V. Beccabunga*), superficially resembling watercress, is abundant in ditches, watercourses, and wet places in Britain, and common throughout the palaearctic region. Several of the shrubby species of *Veronica* of peculiar and ornamental character, natives of the mountains of New Zealand, are now plentiful, and prove perfectly hardy, in British gardens.

Speler, or SPIRES, the capital of the Bavarian Palatinate, stands on the left bank of the Rhine, 19 miles S. of Mannheim. The most noteworthy edifice is the Romanesque cathedral, built of red sandstone, which has had a very chequered history. Begun by Conrad II. in 1030 and finished in 1061, it suffered from fire in the 12th, 13th, and 16th centuries, and in 1689 was stripped to the bare walls and even set fire to by the French, who also exhumed and scattered the bones of eight German emperors

(from Conrad II. to Albert I.) who lay buried in its crypt. Reconstructed in 1782, it was again desecrated by the French in 1794, but was once more rebuilt in 1797-1822. The interior walls are covered with more than thirty large frescoes by Schrandolph; statues of the eight emperors by Fernkorn (1858) adorn the vestibule; and in front of the west façade is the ancient 'Domnapi,' or cathedral basin. The town itself was also demolished by the French in 1689, and having been rebuilt since that date has broad though irregular streets, but very few ancient buildings, except the gateway or clock-tower (*alta porta*), dating from before 1246, and a few fragments of the imperial palace (Ketscher), in which several diets were held. The place, which has a museum and picture-gallery, never recovered its position, and the trade and manufactures—cloth, paper, tobacco, sugar, vinegar, machinery, shoes—are unimportant. Pop. 23,000. Speier was known in Roman times as *Augusta Novetum* and *Noviomagus*, but was known as *Spira* from the 7th century. Previous to that, however, it had experienced repeated disasters at the hands of the successive barbarian armies that swept westwards. The early emperors showed it considerable favour, and in the 13th century it became a free imperial city. Several imperial diets were held within its walls, especially that of 1529, at which the reformers first acquired the name of Protestants; and from 1513 to 1689 it was the seat of the supreme law court of the empire. But the repeated devastations it endured in the Thirty Years' War and from the French (see above) ruined its prosperity. It was the capital of a department of France between 1801 and 1814, and in 1815 passed to Bavaria. In the early years of the 20th century, for the safety of the cathedral, important structural repairs from foundation to roof were carried out.

Speiss. This name is given to the product first obtained (an arsenide of the metal) when arsenical ores are smelted. See COBALT, NICKEL.

Speke, JOHN HANNING, an explorer of Africa, was born on 4th May 1827 at Jordans in Somersetshire, entered the Indian army when seventeen, and saw some active service in the Punjab. During peace he spent great part of his time in making shooting expeditions into the Himalayas, in the course of which he collected natural history specimens and did a good deal of route-plotting. In 1854 he joined Burton in an excursion into the Somali country, and barely got back with his life. Three years later the Royal Geographical Society sent out the same two travellers to search for the great equatorial lakes of Africa. Speke, whilst travelling alone, discovered the Victoria Nyanza, and was convinced that it was the head-waters of the Nile. In 1860 he returned in company with Captain J. A. Grant (q.v.); died 10th February 1892, and not only explored the western and northern shores of the large lake he had previously discovered, but followed the Nile far enough down its course to establish its identity with the great river of Egypt. Nevertheless his identification was disputed by Burton and others; and Speke was to hold a public discussion with Burton at the British Association meeting at Bath on 15th September 1864, when, on that very morning, he accidentally shot himself whilst out shooting near that city. He wrote *Journal of the Discovery of the Source of the Nile* (1863), and *What led to the Discovery of the Source of the Nile* (1864).

Spell. See INCANTATION.

Spelling is originally phonetic, its aim to convey to the eye the sound heard by the ear; but in modern English the usage of pronunciation has drifted far from the conventional forms established

by a traditional orthography, with the result that the present spelling of our written speech is to a large extent a mere exercise of memory, full of confusing anomalies and imperfections, and involving an enormous and unnecessary strain on the faculties of learners. The modern English alphabet consists of twenty-six letters, of which five are vowels, and of these not even the consonants are consistent in sound, as may be readily seen in the current pronunciation of such words as *give, gin; cent, cant; thin, this; cough, dough, songh, hic-cough, hough; loch, arch, patriarch*. Some again are superfluous, as *c, q, x*, their sounds being capable of being represented by other letters; while others may remain silent in pronunciation, as seen in *through, plough, debt, knell, write, lamb, malign, demesur*. Further anomalies appear in *walk, folk* as opposed to *watt, fault*; while a stranger series still appears in such words as *colonel, lieutenant, foreign, scent, island, scythe, scissors, ache, sceptic*. Again, the same vowel or diphthong meets us in such varying forms as the following (from Lounsbury's lists): the short *e* variously in *met, sweat, any, said, says, jeopardy*; the long *e* in *meet, mete, meat, machine, grief, receive, key, quay, people, ægis*. Again, take the varying forms of the same vowel-sound in *rude, ued, road, routine, themn, drein, shoe, move, house*; while on the other hand six different sounds have the same form in *sour, pour, would, tour, sought, couple*; and five in *heat, sweat, great, heart, heard*. Groups of words like *man, law, ask, salt* on the one side, and *why, wine, eye, lie, or air, heir, eyre, ere, eer* on the other, show equally a violation of the fundamental principle of all rational spelling—viz. that of representing every sound by an invariable symbol.

Examples enough have been given to demonstrate the utterly unscientific character of English spelling; it now remains to ask how this has originated, and whether any measure of relief from such a burden is practicable. It was only slowly that this modern uniformity became rigid, and we may dismiss as completely without foundation the defence put forward by pre-scientific philologists like French that the modern spelling is valuable as preserving an index to the derivation. Even if this were true, are we justified in paying so great a price for an end so little? But when we look at the facts we find that if the conventional spelling in some few cases preserves a hint as to the ultimate origin, as in *know, debt*, it is far more often the case that it obscures the order of descent, or merely preserves some error, as in words like *island, controller, whole, could*. Again, the infallible writers for the press talk with indignation of being divorced from the tongue of Shakespeare and the Bible; but, as Sir James Murray says, the slightest glance at 17th-century orthography will show what an immense amount of spelling reform has been done since then. One of the most important spelling reforms in English was that made about 1630 when *u* was made a vowel and *v* a consonant, for up to that time these were only forms of the same letter having a position-rank like long *f* and short *s*. From the 14th century onwards a fashion grew of adapting the spelling of words to their supposed Latin originals, with what confusion to the real history of the words may be imagined from the accidental or capricious errors of sciolists innocent of scientific method. But generally speaking up to the 16th century English spelling was mainly phonetic like the present German. The old scribes allowed themselves large liberty in the forms they adopted, to which Chaucer refers in the well-known lines, 'and for there is so great diversity in English, and in writing of our tonge.' The *Ormulum* is an interesting example of a consistent attempt at a

phonetic spelling. But as literature developed and the printing-press began to assert its authority the spelling became more and more fixed, till at last it became quite stationary, while the pronunciation continued to go on changing without intermission until, as Sweet says, our present spelling does not represent the English we actually speak, but rather the language of the 16th century. This progress towards uniformity went on actively during the 17th century, but it was Johnson's *Dictionary* (1755) that gave universality to the currency. Meantime spoken language grew, and natural divergencies arose, resulting in the modern pronouncing dictionary, which French called with justice 'the absurdest of all books.'

Halliwell-Phillipps tells us Shakespeare spelt his name in some thirty different forms; the young Pretender writes of his father: indifferently as *Jems* or *Gems*; Claverhouse, says Macaulay, spelt like a washerwoman; and the great Marlborough used the same freedoms as Thackeray's *Jeames* or the ordinary Englishman whose education stopped short for ever at the Fourth Standard. But we may remember that Will Honeycomb never liked pedantry in spelling, and spelt like a gentleman, not like a scholar. And we must not suppose that great as was Johnson's influence all his spellings have been accepted. His *miscre, ambassador, horror, rimeter, waterfall, parsnep, skeptick, sack-cloth*, have disappeared; but some of his strange pairs of inconsistencies survive: *uncoverable* and *unmorale*, *chilifactory* and *chyle*, *bias* and *unbiased*. Webster in his 1828 edition gives us many original spellings, as *melasses, pretense*, all of which were swept away in the revision of 1864. Julius Hare and Thirlwall adopted such forms as *forem, sorcerem, cherisht, preach*; Ritson's habit of adding *-ed* for the preterite of all verbs was but one among many of the whimsical notions of a half-crazy antiquary. Pinkerton's vagaries are beneath notice; the usages familiar to readers of Dr Furnivall's 'fore-words' belong to quite another category, and might be commended altogether, but for the saving caution of Dr Sweet that 'nothing can be done without unanimity, and until the majority of the community are convinced of the superiority of some one system unanimity is impossible.' For spelling reform must proceed by a wise moderation, and Englishmen as yet are far from being ready for such elaborate systems as the Glossic of Ellis, the Romie of Sweet, and the other systems desired by phoneticians. But to these scholars the cause owes all the progress it has made, and their names will live in honoured memory when rational principles at last prevail over the tremendous forces of inertia and prejudice. It is hard to reason men out of beliefs they have never been reasoned into, and it may yet be long before our children are relieved of an unnecessary burden too heavy to be borne. That we can still read Chaucer and *Piers Plowman* despite Johnson's *Dictionary* should dispose of the one specious difficulty objected to reform; another—viz. that uniformity would confound such homonyms as *write, rite, right, and wrright*—is answered by the fact that the identity of sound troubles us little in speaking, and would trouble us still less in reading, with the help of the context before us. Meantime the true path of progress might follow such wisely moderate counsels as those of Sir J. Murray: the dropping of the final or inflexional silent *c*; the restoration of the historical *-t* after breath-consonants; uniformity in the employment of double consonants, as in the American *traveler*, &c.; and the discarding of *ur* in words like *demagogue* and *catalogue*; the uniform leveling of the agent *-our* into *-or*, already so common in America; the making of *ea* = *e* short into *e* and

the long *ie* into *ee*: the restoration of *some, come, tongue*, to their old English forms, *sum, cum, tung*; a more extended use of *z* in the *vow* of words, as *chosen, prize, raise*; and the correction of the worst individual monstrosities, as *foreign, scent, scythe, ache, debt, people, parliament, court, would, sceptic, phthisis, queue, schedule, twopence-halfpenny, yeoman, sieve, gauge, barque, buoy, yacht, &c.*

An encouraging success is the improvement of German spelling, introduced in 1880, the chief features of which are the omission of all superfluous signs indicating the lengthening of a syllable, the substitution of *f* for *ph*, the determination of the sound of *s* hard and soft, the use of *sz*, the doubling of consonants, the retention of *h* as indicating vowel-lengthening only in root-syllables: *Akt, Armut, Elefant, tot, Irrtum, Wert*.

See PHONETICS, PHILOLOGY, ALPHABET, ENGLISH LANGUAGE.

Spelman, SIR HENRY, antiquary, was born in 1562, son of a gentleman of ancient family, at Congham in Norfolk. He was educated at Trinity College, Cambridge, whence he passed to Lincoln's Inn. He was high-sheriff of Norfolk in 1604, and was often employed in public affairs at home and in Ireland by James I. Knighted by the king, he retired in 1612 to prolonged private studies, and died in 1641. His ponderous *Glossarium Archæologicum*, of which he published A—I in 1626, was completed by his son, Sir John Spelman, and William Dugdale. His next great work, *Concilium, Decreta, Leges, Constitutiones in Re Ecclesiastica Orbis Britannici* (1639-64), he also left incomplete. His other works on Tithes, on Sacilege, are no less learned, and exhibit his strong devotion to the Church of England. His *Reliquiæ Spelmanianæ* were edited, with a Life, by [Bishop] Edmund Gibson (1698).—His eldest son, SIR JOHN SPELMAN, inherited all his tastes and part of his learning. He was knighted in 1641, and died in 1643, author, besides other works, of a life of King Alfred (in Lat. trans. 1678; Spelman's Eng. original, edited by Thomas Hearne, 1709).

Spelter. See ZINC.

Spennborough, an urban district of the West Riding of Yorkshire, between Leeds and Huddersfield, and between Bradford and Dewsbury, was formed in 1917 by the union of Cleckheaton, Gomersall, and Liversedge; pop. (1921) 31,114.

Spence, JOSEPH, anecdotist, was born at Kingsclere in Hants, 25th April 1699. A sickly boy, he went to Eton, but in a short time left it for Winchester, thence passing to New College, Oxford, in 1720, of which he became a fellow in 1722. He took orders in 1724, three years later became professor of Poetry, and was presented to the rectory of Birchington in Essex. He travelled on the Continent with the Earl of Middlesex, afterwards second Duke of Dorset (1730-33), again with Mr Trevor (1737), and Henry, Earl of Lincoln, afterwards Duke of Newcastle (1739-42). Before first going abroad he had published his *Essay on Pope's Odyssey* (1726), which procured him the lasting friendship of the poet. Almost from the beginning of their intimacy he began to record Pope's conversation and the incidents of his life, to which gradually many curious particulars were added gathered from the conversation of other eminent men. In 1736 he edited *Gorboduc*, and in 1737 became rector of Great Harwood in Bucks, and regius professor of Modern History. In 1747 he published his *Polymetis*, which is said to have brought him £1500, great part of which he spent on landscape-gardening at Byfleet in Surrey. In 1754 he became a prebendary of Durham. He was accidentally drowned at

Byfleet, August 20, 1768. He was a constant friend to Pope, Horace Walpole, Shenstone, and Lowth, and was noted for his large charity, a devoted love to his aged mother that rivalled Pope's own, and his kind patronage of such men as Stephen Duck, thresher and poet; Robert Hill, the learned tailor; Thomas Blacklock, the blind poet; and Robert Dodsley, footman before publisher.

His MS. collection of Anecdotes was given by his executors to the Duke of Newcastle, who did not approve of their being published. Some, however, reached the public through Warburton, Warton, Johnson, and Malone—in the case of the first two from Spence himself. Malone's edition (1820) was quickly superseded by that of S. W. Singer (1820; 2d ed. 1858), printed from the original papers, with notes and a memoir.

Spencer, a town of Massachusetts, 64 miles by rail W. by S. of Boston, with manufactories of boots and woollens. Pop. 6000.

Spencer, a family which has given several statesmen to the service of their country, was founded by the Hon. John Spencer, youngest son of the third Earl of Sunderland, by Anne, daughter and co-heiress of the great Duke of Marlborough. He inherited much property from his grandmother, Sarah, Duchess of Marlborough, and his only son, JOHN (1734-83), was made Earl Spencer in 1765.—GEORGE JOHN, second Earl (1758-1834), was First Lord of the Admiralty under Pitt's administration (1794-1801), the period of the great naval victories of Camperdown, Cape St Vincent, and the Nile. He retired when Addington became premier, and was famous as a munificent collector of rare books and the first president of the Roxburghe Club. The Spencer Library, dispersed under the hammer in 1881-83, brought £50,581. See his *Private Papers* (ed. Corbett and Richmond, Navy Rec. Soc., 1913 *et seq.*).—JOHN CHARLES, third Earl Spencer, better known under the courtesy title of Lord Althorp, was born in 1782, and educated at Harrow and Trinity College, Cambridge. He entered parliament in 1804 for Oakhampton, and became a junior Lord of the Treasury when in 1806 his father took office as Secretary of State for the Home Department in the Grenville-Fox ministry. He sat for Northamptonshire from this time till the Reform Bill, and in the Reformed parliament for the southern division of the county. He went out with the Whigs in 1807, and gave steady opposition during the long Tory reign thereafter. On the dissolution of the Wellington cabinet in November 1830 he became Chancellor of the Exchequer and leader of the House of Commons in the celebrated Reform ministry of Earl Grey. The Reform Bill was introduced by Lord John Russell, but the task of carrying the bill mainly devolved upon Spencer. In 1833 he brought in and carried the ministerial bill for reforming the Irish Church. In this memorable working session the curious statistician discovered that Spencer, who had, from his post of ministerial leader, naturally been the most frequent speaker, had addressed the House 1026 times, his speeches occupying 387 columns in the then *Mirror of Parliament*. When the Irish Coercion Bill was under consideration in the cabinet Spencer had opposed the clauses prohibiting public meetings, yet had given way rather than break up the ministry, but when the truth was elicited in debate by Mr O'Connell he resigned. He was considered and described by Earl Grey as his 'right-hand man,' and without his assistance the earl felt himself unable to carry on the government. The administration of Viscount Melbourne succeeded (July 1834), in which Spencer consented to resume his office. In November he was called by the death of his father to the House of Peers, which had the effect of bringing the Melbourne administration to an end. When the attempt of

Sir Robert Peel to carry on the government failed Spencer declined to take office again. He devoted his time to agricultural pursuits, became president of the Smithfield Cattle Club, and suggested the formation of the Royal Agricultural Society, of which he was elected president in 1838. He died at his seat, Wiseton Hall, Notts, October 1, 1845, without issue, and was succeeded by his brother. During his political career his simplicity of character and integrity of purpose obtained for him the appellation of 'honest Lord Althorp.' He was very little of an orator, but he had a clear and practical intellect, and his influence over the Reformed House of Commons was supreme. Lord Brougham dedicated to him his work on *Natural Theology*; and his *Dialogues on Instinct* are also supposed to be carried on with Spencer, to whose cultivation of philosophy in the midst of his political and agricultural pursuits the author bears friendly testimony. See *Memoir* by Sir Denis Le Marchant, Bart. (1876), Walter Bagot's *Biographical Studies* (1881), and Ernest Myers' *Lord Althorp* (1890). —JOHN POYNTZ SPENCER, fifth earl, was born October 27, 1835, and was educated at Harrow and Trinity College, Cambridge. He had sat but a few months in the House of Commons for South Northamptonshire when the death of his father in 1857 sent him to the House of Lords. He was Lord-lieutenant of Ireland in 1868-74 and 1882-85; in 1880-83 and 1886 Lord-president of the Council; in 1892-95 first Lord of the Admiralty; and from 1902 to 1905, when his health broke down, Liberal leader in the House of Lords. He died 13th August 1910. He embraced Gladstone's Home Rule policy, having during his tenure of office at Dublin Castle come to the conclusion that coercion was a failure.

Spencer. HERBERT, who devoted his life to the elaboration of a system of philosophy that should be in harmony with evolution and the results of modern science, was born at Derby, 27th April 1820. His father was a schoolmaster in that town, and secretary of the Philosophical Society; and from him Spencer imbibed that love of natural science and wonderful faculty of observation so conspicuous in his works. The father was greatly interested in entomology; and Spencer himself used to collect, describe, and draw insects when a boy. Insurmountable aversion to linguistic studies put a Cambridge career out of the question, and at the age of seventeen he entered upon the profession of a railway engineer under Mr (afterwards Sir Charles) Fox, in London; but about eight years afterwards he gave up this profession, which lacked interest for him. He had already contributed various papers to the *Civil Engineers' and Architects' Journal*; and in the latter half of 1842 he wrote a series of letters to the *Nonconformist* newspaper on 'The Proper Sphere of Government,' which were republished in pamphlet form in 1843. These letters imply a belief in human progress based on the modifiability of human nature through adaptation to its social surroundings, and maintain the tendency of these social arrangements 'of themselves to assume a condition of stable equilibrium.' From 1848 to 1853 he was sub-editor of the *Economist* newspaper; and at this time he developed the ethical and political consequences of the ideas he had already enunciated, and sought an independent basis for them. Hence his first important work, *Social Statics* (1850; abridged and revised, 1892). It is thus noticeable that Spencer's philosophical activity began with ethical and social questions. The conception of the evolution of man and society as determined by circumstances, and the idea that organic and social evolutions are under the same law, preceded the elaboration of those scientific ideas which, in the complete *System*

of *Philosophy*, are made to serve as their basis. The truth anticipated by Harvey and Wolff, but first put into definite shape by Von Baer—'the truth that all organic development is a change from a state of homogeneity to a state of heterogeneity'—is regarded by Spencer as the organising principle of his subsequent beliefs. It was gradually developed and applied by him in a series of articles contributed in the following years to the *Leader*, the *North British*, *British Quarterly*, *Medico-Chirurgical*, *Westminster*, and other reviews.

In these essays, especially those on *The Development Hypothesis* (1852), *Manners and Fashion* (1854), *The Genesis of Science* (1854), and *Progress: its Law and Cause* (1857), and in the volume of *Principles of Psychology* (1855), the doctrine of evolution began to take definite form, and to be applied to various departments of inquiry. The publication of Darwin's *Origin of Species*, in 1859, gave a wide basis of scientific proof for what had hitherto been matter of speculation, and first showed the important part played by natural selection in the development of organisms.

In 1864 Spencer published an essay on the *Classification of the Sciences*, in which he criticised Comte's serial arrangement of the sciences according to generality, and substituted for it a classification according to abstractness: (1) *Abstract Science*, treating of the forms (space and time) in which phenomena are known to us—logic and mathematics; (2) *Abstract-concrete Science*, treating of the laws of the factors of the phenomena themselves—mechanics, physics, chemistry, &c.; (3) *Concrete Science*, treating of the phenomena in their totalities (the laws of the products)—astronomy, geology, biology, psychology, sociology, &c.

Upon this scheme of the sciences Spencer had now been working for several years. As early as 1860 he had announced the issue of a *System of Synthetic Philosophy*, already in course of preparation, which, beginning with the first principles of all knowledge, proposed to trace how the law of evolution was gradually realised in life, mind, society, and morality. In pursuance of this comprehensive design Spencer had published *First Principles* (1862); *Principles of Biology* (2 vols. 1864-67); *Principles of Psychology* (2d ed. 2 vols. 1870-72); *Principles of Sociology* (3 vols. 1876-96); *Principles of Ethics* (2 vols. 1879). In the preface to the third vol. of the *Sociology* (1896) completing the *Synthetic Philosophy*, the author explained that the two volumes of the original design had expanded to three; a fourth (Linguistic, Intellectual, Moral, Aesthetic) must remain unwritten by reason of age and infirmity.

These works follow a different plan from his earlier writings. In his occasional essays already referred to he proceeded by means of observation and induction; and in them the law of evolution was the result of a generalisation. But the method of his *System* is deductive; though the deductions, large and small, are always accompanied by inductive verifications. Even the law of evolution only finds a place in it because it can be deduced from a higher and ultimate principle. Just as certain special sciences—mechanics, for example—have already entered into the deductive stage, so, in Spencer's *System*, completely co-ordinated knowledge, to which he gives the name of philosophy, becomes deductive. Hence the importance of determining what is the ultimate test of truth. This, according to him, is the mental inconceivability of the negation of the proposition by the individual thinker. The validity of this test is supported, according to him, by two considerations: first, because no other test is obtainable, and secondly, by the consideration

that mental inconceivability is the result of certain uniformities in our experience which are due to uniformities in nature. His appeal to this test, and the way in which he employs it, formed the subject of a controversy with J. S. Mill, and brings out the distinction between his method and principles and those of the empirical philosophy.

Metaphysically, Spencer's system is founded on the doctrine of relativity deduced by Hamilton and Mansel from Kant, but carried by him, as he says, a step further. Along with the definite consciousness of things known in relation to one another there is implied an indefinite consciousness of an absolute existence, in the recognition of which as inscrutable science and religion find their reconciliation. All definite consciousness or knowledge is of the manifestations of this unknowable power; and knowledge, completely unified, is philosophy. The data of philosophy are necessarily those organised components of our intelligence without which philosophising could not go on. 'Our postulates are: an unknowable power; the existence of knowable likenesses and differences among the manifestations of that power; and a resulting segregation of the manifestations into those of subject and object.' Within each segregated mass there are likenesses and differences involving secondary segregations. The modes of cohesion under which manifestations are invariably presented are called, when contemplated apart, space and time; when contemplated along with their manifestations, matter and motion. All these are traceable to experiences of that mode of consciousness whose reality is shown by its persistence—to force. By the 'persistence of force' is meant the unchanging quantity both of that mode of force which is revealed to us only by opposition to our own powers, and is not a worker of change, and of that mode which is a worker of change actual or potential, and is specifically termed energy. The persistence of force—i.e. the persistence of some cause which transcends our knowledge and conception—is the truth which all other truths imply, and from which they all (including the law of evolution) are derived. From the fact that force can neither arise out of nor lapse into nothing follows the uniformity of law. Force never disappears; it is only transformed. Motion follows the line of least resistance, and is perpetually reversed within limits—is rhythmical. So far of the factors of phenomena. The phenomena themselves must be under a law of the concomitant redistribution of matter and motion, which holds of every change. The law of the entire cycle of changes passed through by every existence is loss of motion and consequent integration—i.e. evolution, eventually followed by gain of motion and consequent disintegration—i.e. dissolution. In its complete shape the 'formula of evolution' is thus stated: 'Evolution is an integration of matter and concomitant dissipation of motion; during which the matter passes from an indefinite incoherent homogeneity to a definite coherent heterogeneity; and during which the retained motion undergoes a parallel transformation.' This law of evolution applies equally to all orders of phenomena—'astronomic, geologic, biologic, psychologic, sociologic, &c.'—since these are all component parts of one cosmos, though distinguished from one another by conventional groupings. So long as evolution is merely established by induction it does not belong to philosophy. It must be deduced from the persistence of force. And this can be done. For any finite aggregate being unequally exposed

and those which are similar to cluster together ('segregation'); and this subdivision and dissipation of forces, so long as there are any forces unbalanced by opposite forces, must end at last in rest; the penultimate stage of this process, 'in which the extremest multifariousness and most complex moving equilibrium are established,' being the highest conceivable state.

The various derivative laws of phenomenal changes are thus deducible from the persistence of force, and it remains to apply them to inorganic, organic, and super-organic existences. The detailed treatment of inorganic evolution is omitted from Spencer's plan (which is, he remarks, even too extensive without it), and he proceeds 'to interpret the phenomena of life, mind, and society, in terms of matter, motion, and force.'

It is impossible to give here any but the most general idea of the contents of the volumes in which the law of evolution is applied to these different departments. It is not only made to account for the phenomena within each group, but also for the connection between one science and another. The researches of Darwin had accumulated ample material for showing the continuity of development, structural and functional, in plants and animals; and Spencer's view of biology, and the definition of life he proposes ('the definite combination of heterogeneous changes both simultaneous and successive in correspondence with external co-existences and sequences'), are meant to show its connection both with inorganic changes on the one hand and with mind on the other. Now, just as biology has to deal with the connection between phenomena in the organism, and as physical science treats of the connection between phenomena in the environment, so psychology has to do with the connection between these two connections. For this is said to be the objective aspect of what states of consciousness are subjectively. The functions dealt with by the psychologist are more special than those dealt with by the biologist; but they belong to psychology, not merely because they are more special, but also because they are the counterparts of the states of consciousness dealt with by the science of subjective psychology.

Objectively, an attempt is made to trace the evolution of mind from reflex action through instinct to reason, memory, feeling, and will, by the inter-action of the nervous system with its environment. Subjectively, mental states are analysed, and it is contended that all of them—including those primary scientific ideas, the perceptions of matter, motion, space, and time, assumed in the *First Principles*—can be analysed into a primitive element of consciousness, something which can only be defined as analogous to a nervous shock. These perceptions have now become innate in the individual. They may be called—as Kant called space and time—forms of intuition; but they have been acquired empirically by the race, through the persistence of the corresponding phenomena in the environment, and from the accumulated experiences of each individual being transmitted in the form of modified structure to his descendants.

This principle of heredity is one of the laws by which individuals are connected with one another into an organic whole; and we thus pass quite naturally to what Spencer calls super-organic evolution, implying the co-ordinated actions of many individuals, and giving rise to the science of sociology. Society, like an individual man, is shown to be an organism from the fact and laws of its growth, the nature of its activities, and the inter-dependence of its parts; though it is distinguished from the individual organism in this,

structure; every differentiated part will become the parent of further differences; at the same time, dissimilar units in the aggregate tend to separate,

that it is discrete, while the latter is concrete: 'there is no social sensorium.' As societies progress in size and structure, they work on another profound metamorphoses, now by war-struggles and now by industrial intercourse.

Assisted by a series of elaborate ethnographical charts (*Descriptive Sociology*) prepared under his direction, Spencer attempted to trace the development of human ideas, customs, ceremonial usages, and political institutions. The series continues under direction of trustees. The genesis of religion is traced to Ancestor-worship (see ANCESTORS, WORSHIP OF), or generally to worship of the dead. The notion of another life—from which the notions of gods and God are gradually evolved—is originated mainly by 'such phenomena as shadows, reflections, and echoes'—these being looked upon as indications of a 'double' or other self, which is not extinguished with the death of the first self. It is this fear of the dead which is the root of the religious control, just as it is the fear of the living which is the root of the political control. Ceremonies and institutions alike have their root in this fear of the stronger and submission to the conqueror. Thus, early communities being of the predatory or militant type, tended to centralised control; while industrial communities, which are now most frequent, should tend to free institutions and to the restriction of the sphere of government to the negative duty of preventing the interference of one individual with his neighbour's liberty. This principle of government—commonly expressed by the maxim *laissez faire*—is energetically enforced by Spencer, against the tendency of much recent legislation. A still higher type than the industrial is possible in the future, by inverting the belief that life is for work into the belief that work is for life; just as the industrial type inverts the belief that individuals exist for the state into the belief that the state exists for individuals.

The principles of morality are looked on by Spencer as the copstone of his system, all his other investigations being only preliminary to them. Ethics, he holds, has its root in physical, biological, psychological, and social phenomena, for by them the conditions of human activity are prescribed and supplied. The best conduct is that which most fully realises evolution—which promotes the greatest totality of life in self, offspring, and the race—the balance of egoism and altruism being attained by a compromise between these contending principles. The measure of life is said to be pleasure, but the Utilitarian school are at fault in assuming that the end (greatest happiness) is better known than the means to it (morality); and in ignoring the fact that accumulated experiences of utility have become consolidated in the superior races into a moral sense.

In the above summary it has been impossible to give any idea of either the strength or weakness of the proof by which this elaborate system is supported. In general, it may be said that its strength lies in the author's brilliant power of generalisation, his acquaintance with many departments of science, and his unsurpassed wealth of illustration. The wide knowledge which all his writings display of physical science, and his constant endeavour to illustrate and support his system by connecting its positions with scientific facts and laws, gave his philosophy great currency among men of science—more so, indeed, than among philosophical experts. At the same time, not only did the development and application he gave to the theory of evolution profoundly influence speculation and the developments of psychology and ethics, but he must also be regarded as one of the very few modern thinkers who have carried out the attempt to give a

systematic account of the universe in its totality. He died 8th December 1903; and his *Autobiography* (1904; supplemented in 1908 by the *Life and Letters* by Druce) gives a remarkable picture of a life devoted to one great task.

Spencer's most popular works have been a small volume on *Education* (1861), which has been translated into many languages, and *The Study of Sociology* (1872), which points out to the unscientific reader the difficulties of a social science. He also wrote *The Man versus the State* (1884), and *The Factors of Organic Evolution* (1887). His occasional papers were collected and published in three volumes of *Essays: Scientific, Political, and Speculative. An Epitome of the Synthetic Philosophy*, by F. Howard Collins, was published with Spencer's authority in 1889 (1 vol.); there are criticisms of the system by Guthrie (1879 and 1882) and McCosh (New York, 1885); and the *Outlines of Cosmic Philosophy*, by John Fiske (2 vols. Boston, 1874), is based on Spencer's system. See also Fischer, *Ueber das Gesetz der Entwickelung*.

Herbert Spencer: The Completion of the Synthetic Philosophy (1897); Hector Macpherson, *Herbert Spencer, the Man and his Work* (1900); J. Arthur Thomson, *Herbert Spencer* (1906); H. S. R. Elliot, *Herbert Spencer* (1917).

SPENCER, SIR WALTER BALDWIN, ethnologist, born at Salford, Lancashire, in 1860, studied at Manchester and Oxford, and in 1887–1919 was professor of Biology at Melbourne. With F. J. Gillen he crossed Australia from south to north, and jointly they produced standard works on the natives: *The Native Tribes of Central Australia* (1899), *The Northern Tribes of Central Australia* (1904), and *Across Australia* (1912). As commissioner and chief protector of aborigines he reported in *The Native Tribes of the Northern Territory* (1914).

SPENCER, WILLIAM ROBERT, minor poet, was second son of Lord Charles Spencer, himself the second son of that Charles Spencer, fifth Earl of Sunderland, who succeeded as third Duke of Marlborough in 1733. He was born in 1770, was educated at Harrow and Oxford, held a Commissionership of Stamps, spent his last ten years in Paris, and died there in 1834. Among his children were Ambrey-George Spencer, Bishop of Jamaica, and George-John-Trevor, Bishop of Madras. He was long a fashionable writer of *vers de société* and such like, but his fashionable verse is clean forgotten, and his name lives alone in a few simple songs and ballads, the chief 'Beth Gdert, or the Grave of the Greyhound.' Yet even these are but commonplace. His poems were collected, with a brief Memoir, in 1835.

Spencer Gulf, a deep inlet on the coast of South Australia, between Eyre's Peninsula on the W. and Yorke Peninsula on the E. It is 180 miles in length, by 90 in greatest breadth.

Spence's Metal is made by melting together a metallic sulphide, such as sulphide of iron, along with sulphur. The result is a grayish-black substance, without metallic lustre, which takes a good polish. It can be coloured to imitate bronze and other metals, and as it melts at 320° F. it can readily be cast into moulds from which it takes a sharp impression. It is used by dentists for moulding. Busts, medallions, &c., have been made of it, and it is also used like lead for the joints of pipes. It is but slightly acted on by acids. First made in 1879, it is more of the nature of a hard cement than a metal.

SPENCER, PHILIPP JAKOB, an illustrious German reformer, and the founder of the movement known as *Pietism*, was born at Rappoltswiler in Upper Alsace, 13th January 1635. Pious from his cradle, he studied at Strasburg, where in Johann Schnid he found his 'father in Christ.' Next he studied under the younger Buxtorf at Basel, afterwards

visiting Geneva, Stuttgart, and Tübingen. In 1663 he became a preacher at Strasburg, and three years later was transferred to Frankfurt, and here he laboured with the most devoted zeal to reawaken the dormant and mechanical Christianity of the day by constant catechising and earnest preaching based on Scripture and Christian experience. Yet Spenser was the very opposite of what is commonly called a mystic. The devotion which he sought to excite was not to show itself in transcendental ecstasies, but in acts of piety, humility, and charity. He had a strong aversion to formal theology, which he considered a hateful caricature of the free word of life; and he commenced in the year 1670, at his house, meetings for the cultivation of evangelical morality. Out of these grew the famous *collegia pietatis*, whose influence for good on the German character, in those days of stony and barren orthodoxy, cannot easily be overvalued. His earnest and plain-spoken *Pia Desideria* (1675) spread the movement far beyond the range of his personal influence, but aroused the enmity of many in high places. In 1686 he became court preacher at Dresden and member of the Upper Consistory. Here he infused new life into the theological teaching of the university of Leipzig, despite the opposition of Carpzov and others; but, having, in 1689 rebuked the Elector Johann Georg III. for his vices, he soon found his position so intolerable that he gladly accepted an invitation to Berlin to become Provost of the church of St Nicholas and consistorial inspector, offices which he retained to the end of his life. The Elector of Brandenburg encouraged his efforts after religious reform, and entrusted theological instruction in the new university of Halle to Francke, Breithaupt, Anton, and other disciples of Spenser, the later leaders of the pietistic movement. This excited great irritation in the theological faculties of Wittenberg and Leipzig, which formally censured in 1695 as heretical no less than 264 propositions drawn from Spenser's writings. Spenser died at Berlin, February 5, 1705, leaving behind a reputation for piety, wisdom, and practical Christian energy which all the excesses of the later pietists have not obscured. Indeed Ritschl (*Gesch. des Pietismus*) maintains that he himself was not a Pietist, having no part in their characteristic quietist and separatist instincts.

His writings are numerous; the chief are *Pia Desideria* (1675), *Das geistliche Priestertum* (1677), *Christliche Leichenpredigten* (13 vols. 1677), *Des thätigen Christenthums Nothwendigkeit* (1679), *Klagen über das verdorbene Christenthum* (1684), *Evangelische Glaubenslehre* (1688), and *Theologische Bedenken* (5 vols. 1700-2). See J. G. Walch, *Religions-streitigkeiten der Lutherischen Kirche* (5 vols. 1730-39); the Lives by Hossbach (1828; 3d ed. 1861), Thilo (1841), Wildenhaln (1847; trans. by Wenzel, 1881), and Grünberg (3 vols. 1893-1906).

Spengler, OSWALD, German philosophical speculator, was born 29th May 1880 at Blankenburg (Harz), and studied mathematics and philosophy at the universities of Halle, Munich, and Berlin. After some years spent in teaching, he devoted himself to private study, and in 1918 achieved sudden renown by the publication of the first volume of his *Untergang des Abendlandes*, a book called by the author 'a new outlook on history and the philosophy of destiny.' Cultures, he held, are moved by an inherent destiny, and succeed one another by a process of waxing and waning, eventually dying away like individuals. The decline of our West-European culture gave him a subject for a voluminous but rough-hewn philosophy, which occasioned great interest and greater criticism among all classes in Germany after the war. A second volume of the *Untergang des Abendlandes* appeared in 1922, and

an English translation of volume i. (*The Decline of the West*) by C. F. Atkinson in 1926. Spengler's other works include *Preussentum und Socialismus* (1920), *Der Staat* (1924).

Spennymoor, a town of Durham, 4 miles NE. of Bishop Auckland, with iron-foundries and coal-pits; pop. of urban district, 18,000.

Spenser, EDMUND, one of the chief Elizabethan poets, was, as we learn from the *Prothalamion* (one of his minor poems), born in London, probably in East Smithfield near the Tower. From one of his *Amoretti* the date of his birth can with fair certainty be concluded to be 1552. As to his family, there are many indications that he was well connected, though his circumstances were poor. He speaks of himself as taking his name from 'an house of ancient fame,' and also of 'the noble familie, of which I meaneest boast myself to be.' This noble family was that of the Spencers of Althorp. With the ladies of it he associates several of his poems. Thus in the dedication of *The Tears of the Muses to the Lady Strange* (in honour of whom in her old age it is interesting to notice Milton's *Arcades* was composed) he writes: 'The causes for which ye have thus deserved of me to be honoured (if honour it be at all) are both your particular bounties, and also some private bands of affinity, which it hath pleased your Ladiship to acknowledge.' But in what degree he was connected with the Althorp Spencers has not yet been ascertained; it seems clear it was not a close relationship. What is fairly certain is that the poet's branch of the family belonged to the neighbourhood of Burnley in east Lancashire. Possibly his father came from Hurstwood, near Burnley. Gabriel Harvey, an intimate friend of Spenser's, speaks of Lancashire as Spenser's county; and there is much corroborative evidence of that statement to be drawn from the poet's own works as well as from the Burnley parish registers. But, however 'good' his family, Spenser's father was by no means well-to-do. It is conjectured that he was at one time 'a free journeyman' in the 'arte or mysterie of clothmakinge.' It is certain that his pecuniary means were so limited that in the education of his son, or sons, he was glad of assistance, and that even with assistance the poet went up to the university as a 'sizar.' So from the beginning Spenser did not enjoy worldly prosperity; from the beginning the saying of one of his admirers applies: 'Poorly, poor man, he lived; poorly, poor man, he died.' Of his mother nothing whatever is at present known, except that her Christian name was Elizabeth (*Amoretti*, lxxiv.).

His life appears to have been spent in London till his going up to Cambridge in 1569. The publication of 'The Spending of the Money of Robert Nowell of Reade Hall, Lancashire, brother of Dean Alexander Powell, 1568-1580,' has informed us that he was sent to the Merchant Taylors' School, then newly founded. He is first mentioned in those accounts as one of six 'poor scholars' of the Merchant Taylors' School, to whom the generous squire gave stuff for gowns. Thus Spenser would be a pupil of Mulcaster, though it was certainly not from him he learned to write English—unless indeed Mulcaster's theory was a great deal better than his practice, the style of his *Positions* being singularly affected and discommendable.

The Merchant Taylors' School was directly associated with Pembroke Hall (now College) at Cambridge; and in May 1569 Spenser duly proceeded from one to the other. Nowell's beneficence still attended him. Both at 'his going to Pembroke Hall' and twice at least while there he received presents. And these with the benefits of a sizarship must have reduced his university

expenses to an amount which can have been no great burden to his father and family. As a scholar he does not seem to have specially distinguished himself at Cambridge. Perhaps, like Wordsworth two centuries later, he did not feel himself 'of that hour or that place.' There are traces of some friction between him and the authorities. But it is evident from his works that by the time he quitted the university in 1576 he had obtained a considerable acquaintance with both Latin and Greek literature. And he had made friends of note, who highly appreciated his genius; amongst them Gabriel Harvey and Edward Kike.

And now what to do? He seems to have had no definite programme or prospect. He stayed for some time in the north (perhaps Lancashire), probably waiting on fortune. But this time was not all wasted; he had the experience of an unsuccessful love-suit; he pondered many questions of the day; and he perfected his metrical skill. The *Shepherds Calendar* was the result. And its publication in 1579 made an epoch in English literature. It was the first clear note of the great Elizabethan poetry. His contemporaries heard it with delight, and at once acknowledged its freshness and its charm.

In 1578 Spenser was secretary to the Bishop of Rochester. He had won the friendship of Sir Philip Sidney, to whom the *Shepherds Calendar* was dedicated. This friendship was one of the great events of his life (see *Astrophel, Ruins of Time*, &c.). In 1579 he entered the service of Sidney's uncle, the Earl of Leicester. And no doubt it was through Leicester's influence that in 1580 Spenser, long anxious for some employment or 'place,' was appointed private secretary to Arthur Lord Grey de Wilton, himself just appointed Lord Deputy of Ireland.

Ireland was thenceforward to be his home, little probably as such an issue of his secretaryship was expected, and eager as were his hopes and efforts to obtain some preferment in England. We cannot wonder that Spenser was ill content with his lot. The country was in rebellion when he arrived in it. The special mission of Lord Grey was to suppress the combined insurrection of the O'Neils in the north and the Fitzgeralds in the south, assisted by certain Spaniards who had lately fortified themselves at Smerwick in Kerry, a mission executed with a severity so merciless as to lead to his recall in 1582. Strange and fearful sights were presented to the young poet's eyes, of massacre, of desolation, of utter misery. The evil condition of things is vividly illustrated in Spenser's *View of the Present State of Ireland*—a work of ripe, however bitter, experience, and inspired by long and shrewd observation, written probably in the second decade of his Irish residence, and largely circulated in MS., though not printed till 1633. He strongly advocated the policy of strict repression and suppression. No wonder the natives loved Spenser as little as Spenser loved them. To this day, it is said, the peasants of Cork county remember him with detestation. However, it was in Ireland the unfortunate man was to pass his life, except for some two visits and a terror-stricken flight to England. Before his patron's recall he was already forming fresh connections with the country. In 1581 he was appointed Clerk in Chancery for Faculties. In 1584 he was already Deputy Clerk to the Council in Munster. Probably in 1588 he took up his abode at Kileolman Castle near Doneraile, County Cork, though the grant of it and adjacent lands is dated 26th October 1591. He was certainly settled there in 1589, as we learn from himself in his *Colin Clout's Come Home Again*. His occupancy of

a part of the forfeited estates of the Earl of Desmond must have stimulated the native hatred towards him; and it was probably already keen. Certainly he did much to excite it further by the rigour with which he pressed his rights or supposed rights. Spenser was for the iron flail.

But all this time, amidst all these enmities and horrors, Spenser was going on with his great poem, which, as we know from a letter of Gabriel Harvey's, had been begun before he crossed St George's Channel. The ninth canto of the second book is the first passage that pretty certainly points to his being in Ireland; and all the rest of it that was written was written in Ireland. In his sonnet to Lord Grey he describes his great work as

Rude rymes the which a rustick Muse did weave
In savage soil far from Parnassus Mount,
And roughly wrought in an unlearned loome.

In an interesting account given by his friend Lodovick Brisket of a party assembled at his cottage near Dublin in or about the year 1586, Spenser is reported as mentioning that he had already undertaken a work of ethical purpose 'which is in heroical verse under the title of a *Faerie Queene*,' and that he has 'already well entered into' it. By the year 1589 the first three books were finished, and in that year were shown to Sir Walter Raleigh, whose acquaintance Spenser had probably made some years before (they had certainly met at Smerwick in 1580, if not earlier), and who at this time was in some sort a neighbour, he too having a share (a large one) in the Desmond forfeiture and residing just then at Youghal. Of Raleigh's visit to Kileolman in 1589 and its result in a journey to England and the English court Spenser gives a charming account in his *Colin Clout's Come Home Again*, written immediately after his return in 1591, though not published till 1595, and then slightly revised that it might be in its allusions more nearly 'up to date.' He and his poem were warmly welcomed. In 1590 the three books were published, and there arose a demand for other works of his, which was presently met by the publication of *Sundry Poems*, nine in number, some probably of early composition (as *Proserpina* or *Mother Hubbard's Tale*, and in the main *Bellie's Visions* and *Petrarch's*), others written quite recently (as *The Ruins of Time* and *The Tears of the Muses*). But no place was found for him at the court or in London. Lord Leicester and Sir Philip Sidney were no longer on the scene to support him; and so once more to Ireland.

However, immense fame was his, if nothing of official or pecuniary advantage; and he devoted himself anew to his great work. Its course was interrupted by another great love-passion, of which he describes the various stages from despair to hope and to triumph in his *Amoretti* and his *Epithalamion*. The lady's Christian name was Elizabeth, as we learn from one of the courtship sonnets; her surname is very plausibly conjectured to have been Boyle. His happiness overflows even into the *Faerie Queene*. In book vi. canto x. his lady-love is introduced as a fourth Grace, and is described with much rapture. Finishing now the second three books, and perhaps proudly accompanied by his bride, he paid another visit to England. In 1596 was published the second and last instalment of the *Faerie Queene*, except a fragment consisting of two cantos and two stanzas. To this year also belongs the publication of the great Platonic *Hymns*, the first and second written much earlier. For a time he was the guest of Lord Essex; and under his roof, once that of Lord Leicester, he composed what is probably his last complete poem, *The Prothalamion*, or a *Spousal Verse*. Even in this song of congratulation and

joy his anxiety and distress find expression. He speaks of himself as one

Whom sullen care,
Through discontent of my long fruitless stay
In Prince's Court, and expectation vain
Of idle hopes which still do fly away
Like empty shadows, did afflict my brain

(his emotion overpowering his grammar), and of his 'friendless case.' But again his snit obtained no success; and again he turned his face to the country, not of his choice, but of his necessity.

Meanwhile in that unhappy island a fresh storm had been gathering, and in 1598 burst furiously on the head of the unpopular occupant of Kileolman. One of the first exploits of the new insurrection (that under Hugh O'Neil) was to fire Spenser's castle; and he and his had to flee for their lives. About the close of 1598 or the beginning of 1599 he reached London homeless, destitute, exhausted. On January the 13th (not the 16th, as is usually said; see John Chamberlain to Sir Dudley Carlton, January 17, 1599) he died at a tavern in King Street, Westminster, certainly in distressed circumstances, if not, as Ben Jonson stated to Drummond, and we would fain not believe, 'for lack of bread.' At least in his last resting-place he was happy; he was laid by Chaucer—by him who taught him his songs, as he was proud to say—in the south transept of Westminster Abbey. And, if admiration and fame were or are any compensation for his adverse fortunes, such compensation was and is his in no slight measure. His wealth of language, his fine sense of melody, his abundance of fancy, his ardent patriotism, his profound sympathy with all things lovely and of good report gave him at once and have retained for him a foremost position in English literature. It is his special and his supreme distinction to be known, and with good reason, as the 'Poet's Poet.'

Spermaceti is a waxy matter obtained mixed with oil from the head of the sperm-whale, *Physeter macrocephalus*. The mass obtained from an ordinary sized whale would fill twelve barrels. It is purified by draining off the oil and repeatedly washing with hot water and weak boiling potash-lye. It is in white, pearly, semi-transparent masses, somewhat unctuous to the touch, lighter than water, and melting a little above 38° C. It is insoluble in water, but soluble in ether, chloroform, &c. Medicinally it is no longer given internally, but it is an ingredient of many ointments, to which it gives a crystalline appearance. Chemically it is almost pure cetyl palmitate, but contains small quantities of other fats. See WHALE.

Spermatophyta. See PHANEROGAMIA.

Spermatozoa, the male reproductive cells of animals, the physiological complements of the egg-cells or ova. See EMBRYOLOGY, REPRODUCTION.

Sperm Whale. See WHALE, SPERMACETI.

Spessart, a German forest region mainly in Lower Franconia and north of the Main. The magnificent oak and beech woods are very skillfully managed.

Speusippus (c. 400-339 B.C.), an Athenian philosopher, who, after the death of his uncle Plato, became head of the Platonic school or Older Academy. Of his philosophical works, in which he

taught a doctrine differing but little from Plato's, nothing is left but titles and fragments.

Spey, a river of Scotland, rising at an altitude of 1500 feet above sea-level and running 107 miles north-eastward through or along the boundary of Inverness, Elgin, and Beath shires, until it falls into the Moray Firth at Kingstown between Lossiemouth and Portknockie. The Duhlain and Avon are its principal tributaries. Apart from the salmon-fisheries at its mouth, above which comparatively few fish penetrate, the Spey is almost without value; nor can it generally be called a picturesque stream. It has in its lower course the swiftest current of all the large rivers in Britain, and is subject to sudden and violent freshets, resulting at times in disastrous inundations.

Speyer. See SPIER.

Spezia, a great naval port of Italy, stands near the head of a deep and commodious bay on the west side of the peninsula, 56 miles S.E. of Genoa by rail. It was Napoleon I. who first recognised the suitability of this bay for the purposes to which the Italians, instigated thereto by Cavour, have now put it. An artificial breakwater (built in 1860), 2400 feet long, covers the entrance; whilst formidable batteries of the heaviest artillery (supplemented by torpedo appliances) bristle on the hills that overlook the bay and on the island of Palmaria that guards its entrance. Here the Italians have constructed the great national arsenal, and build their large warships, and have their ship-repairing yards and docks, and their naval victualling yards, store-houses, and so forth. Some of these, however, are at San Bartolomeo, on the opposite shore of the bay. There are also large barracks, a military hospital, schools of navigation, an iron-foundry, and manufactures of armour-plate cables, sail-cloth, and white lead. On the shores of the bay are the private shipyard of Muggiano and the works at Petinsola, where much of the Sardinian lead is smelted. The adjacent country produces excellent olive-oil. The beauty of the bay and the lovely climate cause Spezia to be much frequented as a seaside resort. It was on the shores of this bay at Lerici that Shelley spent the last few months of his life, while at the town of Spezia Charles Lever was consul for ten years. The origin of the town is uncertain, but it was probably founded after the destruction of Luna. It contains nothing of artistic interest, except (in the museum) a number of strange menbers, with rough representations of the human form, from the surrounding country. Pop. of commune (1921) 88,035.

Spezzia (or *Spetsai*; ancient *Pityussa*), a Greek island at the entrance to the Gulf of Nauplia. Area, 6½ sq. m. The town of Spezzia has a good harbor.

Sphaacteria, the small island that closes in the bay of Navarino (q.v.).

Sphaerosiderite, impure earthy or concretionary varieties of carbonate of iron. See CLAY-IRONSTONE, CHALYBITE.

Sphagnum, a genus of Mosses, whose spore-case is an urn closed by a deciduous lid, and its brim toothless, the calyptra irregularly torn. Several species are natives of Britain, and are common in bogs, from which they derive their popular name, *Bog Moss*. They are remarkable for the whitish colour of their leaves. They are very elegant plants. They often grow in considerable masses, absorbing water like a sponge, but becoming friable when dry. They contribute much to the formation of peat. Gardeners employ them in preference to other mosses for covering the roots of plants and keeping them moist, as they have in a high degree the property of absorbing moisture from the atmosphere. They have been

used as food and surgical dressings. The leaf-cells have a spiral structure and large pores in their sides. See MOSSES; and Braithwaite's *Sphagnaceae* (1880).

Sphakia, a small port on the south coast of Crete, 60 miles SE. of Canea. The name of Sphakiotis is, however, given to all the highlanders in the mountains to the north, who were distinguished for their bravery in anti-Turkish risings.

Sphenec. See TITANIUM.

Sphenodon, or **HATTERIA**, the representative of a distinct reptilian order—Rhynchocephalia—which in Permian and Triassic times included several genera. Now there is only one species—*Sphenodon punctatum*, or *Hatteria punctata*—the Tnatara

Fig. 1.—*Sphenodon* (*Hatteria punctata*).

of the Maoris. It was formerly abundant along the coasts of New Zealand, but is now restricted to a few small islands in the Bay of Plenty, both the Maoris and the hogs being blamed for its rarity. It is now carefully protected, and this may save one of the most interesting of 'living fossils.'

In appearance the Hatteria is like an Iguana; on the upper surface the general colour is 'dull olive-green spotted with yellow,' on the under surface whitish; the tail is compressed from side to side and dorsally crested, brittle and replaceable as in many of the genuine lizards. The maximum length of the animal seems to be about two feet, but smaller forms are commoner. Nocturnal in its

habits, the Hatteria lives in holes among the rocks or in small burrows, and feeds on small animals.

But the chief peculiarities of this old-fashioned reptile are internal, and cannot be stated except in technical language. The vertebrae are biconcave like those of most fishes, as is also the case in geckos among lizards and in many extinct reptiles. Some of the ribs bear uncinate processes as in birds and crocodiles. As in crocodiles there are 'abdominal ribs,' or ossifications in the fibrous tissue beneath the skin of the abdomen. The skull, unlike

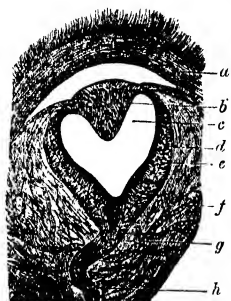

Fig. 2.—Section of Pineal Eye of *Hatteria* (after Baldwin Spencer):

a, a connective-tissue capsule beneath the skin; b, the lens; c, the cavity of the eye; d, e, layers of the retina; f, blood-vessels; g, h, stalk.

that of any lizard, has an ossified quadrate-jugal, and therefore a complete infra-temporal arcade;

the quadrate is immovably united to pterygoid, squamosal, and quadrate-jugal; the pterygoids meet the vomer and separate the palatines. There are teeth on the palatine in a single longitudinal row, parallel with those on maxilla and mandible, and the three sets seem to wear one another away; there is also a single tooth on each side of a sort of beak formed from the premaxillae.

It was in Hatteria first that Baldwin Spencer discovered what seems to be the secret of the pineal body. This structure occurs in all Vertebrates, except the very lowest, at the end of an upgrowth from the 'tween brain or optic thalami. Its import remained for long an enigma. But in Hatteria the pineal body reaches the skin on the top of the head, and retains distinct traces of an eye-like structure—for instance a complex retina. As the same vestigial hint of eye-structure has since been seen in several lizards, many naturalists are confident that the pineal body should be called a pineal or parietal eye, and regarded as a persistent vestige of a median, unpaired, upward-looking sense-organ. See PINEAL GLAND.

Near the living Hatteria the Permian *Paleohatteria*, the Triassic *Hyperodapedon*, and some other important extinct types must be ranked. Nearly allied too is the remarkable *Pterosauros* from the Permian. The development of Hatteria has been studied by Howes, Dendy, and others.

Sphenoid Bone. See SKULL.

Sphenophyllum, a fossil genus (Devonian to Trias) of slender plants with whorled leaves, forming with *Cheirostrobus* the *Sphenophylaceae*. See **PERKIDOPHYTES**.

Sphere, a surface of which every point is equally distant from a definite point known as the centre. It may be described by the rotation of a semicircle (or circle) about its diameter. From every aspect a sphere has the same appearance. Every plane section is a circle—a great circle if the cutting plane contains the centre of the sphere, a small circle in all other cases. The shortest line that can be drawn on the surface so as to join any two points must be an arc of the great circle passing through these two points. If r is the radius of the sphere its volume is $\frac{4}{3}\pi r^3$ and its surface is $4\pi r^2$. These are intimately related to the volume and curved portion of the surface of the circumscribing cylinder, whose height is equal to the diameter of the sphere. The volumes are as two to three, and the surface areas, so defined, are equal.

Spheroid is a species of Ellipsoid (q.v.), and is represented by the same equation. If an ellipse be made to revolve round one of its axes, the curved outline of the ellipse describes the spheroid. Should the major or longer axis be the axis of revolution the spheroid is said to be *prolate*, but if the minor or shorter axis, *oblate*. The Earth (q.v.) is very approximately an oblate spheroid.

Spherometer is an instrument for measuring the sphericity of portions of spherical surfaces—for example, lenses. It rests on three pointed legs, whose points form an equilateral triangle. Midway between these is a fourth leg, which can be screwed up or down as desired through a distance measured by the number of turns given to it. After the spherometer is adjusted on any spherical surface till the four legs are all in contact with the surface it is lifted on to a plane surface and the middle leg screwed up or down until the four legs all lie on the plane. Thus we measure the height of the segment whose base is the circle passing through the equilateral triangle mentioned above, and can by a simple calculation find the radius of the spherical surface. The instrument may also be applied to measure the thicknesses of plates small enough to be pushed within the legs.

Spherical Aberration. See LENSES, and MIRROR.

Spheroidal Condition of liquids is the name usually given to a series of very singular phenomena discovered by Leidenfrost (1715-94), but first carefully investigated by Bontigny (1858). Indeed one, at least, of those phenomena has been popularly known for a very long time, being the foundation of the rough practical method of determining whether or not a flat-iron is so hot as to be likely to singe the linen to which it is to be applied. The test consists simply in letting a drop of water fall upon the iron. The drop will either glance off the surface without wetting it or will spread over the surface and evaporate, according as the iron is or is not too hot.

The common experimental method of exhibiting the spheroidal condition is easily performed thus: A metallic disc, slightly concave, like a watch-glass, is heated by a lamp, and water is cautiously dropped on it from a pipette. If this be done before the disc is sufficiently heated the water boils almost explosively, and is dispersed at once in vapour. But when the disc is

hot enough the water remains suspended, as shown in the cut, above the surface; and the drop, when small, takes nearly the form of an oblate spheroid. The most curious fact connected with the experiment is that the water does not boil. In fact it evaporates so freely that the heat carried off from it, as latent heat, by the vapour which is constantly formed keeps its temperature somewhere about 206° F. only. *Boiling* water, dropped on a red-hot plate of metal, instantly assumes the spheroidal state, and is cooled six degrees below boiling. Other liquids, and even some bodies which are solid at ordinary temperatures, can be easily brought into the spheroidal state—the lowest requisite temperature of the disc being dependent on the boiling-point of the substance. A good example of a solid entering this state is furnished by dropping crystals of iodine on a hot platinum disc. It is not necessary that a metal plate be used. For example, a watch-glass will suffice for the experiment; but *hot* water must be dropped on it, else the glass will crack. Also we may obtain ether, and even water, in the spheroidal state over the surface of hot oil. The explanation of the phenomenon is to be sought for in the existence of a cushion of vapour between the hot plate and the drop. The high temperature of the plate causes a rapid evaporation of the lower surface of the drop. The vapour particles coming into contact with the hot plate are raised in temperature, that is, have their kinetic energy increased. They tend to rebound with increased energy back upon the drop, whose weight they are thus able to support.

An interesting illustration of the spheroidal state is the fact that the hand may be dipped for a short time with impunity into melted lead, and even into melted copper. The vapour instantly raised from the moisture of the skin prevents, so long as that moisture lasts, more than an endurable amount of radiant heat from reaching the hand, and also prevents direct contact.

Spherulitic Structure. See PETROGRAPHY.

Sphex, a genus of hymenopterous insects of the family Sphegidae, closely allied to the true Wasps (Vespidæ). The Sphex wasps are solitary in habit, and there are no workers as in the social forms. The female hollows out, at the end of a long passage, three or four chambers, in each of which she deposits an egg and a store of food for the larva she will never see. The food consists of grasshoppers or other insects, and Fabre gives a minute account of the way in which the Sphex

attacks her victim, and, after a long and violent struggle, throws it on its back and stings it in the neck and between the thorax and abdomen, each time piercing a ganglion. The insect, completely paralysed, but alive, and therefore not liable to putrefaction, is then dragged to the mouth of the nest, where it is relinquished for a short time, while the wasp enters alone to see that all is right. So automatic is this habit of recommitting that if the grasshopper be removed to a little distance the wasp drags it back to the same spot and again enters alone. This was tested by the observer forty times in succession, and each time the wasp paid her preliminary visit of inspection. But, in proof that she is not wholly the slave of habit, it should be noted that when Fabre substituted a fresh grasshopper for the paralysed one she at once perceived the difference, and proceeded to attack and sting her recalcitrant victim. Four paralysed insects are placed in each chamber, which is sealed up as it is finished. When all are full the mouth of the passage is also closed, and the nest is abandoned. In many cases, at least, the mother-insect dies before her offspring emerge. See WASP.

Sphincter Muscles (Gr. *sphinkter*, 'that which binds tight') surround an opening or canal which, by their action, they are able to close or diminish in size. They are found round the mouth, the opening between the eyelids, round the pupil of the eye, the pylorus of the stomach, the outlet of the urinary bladder, and the anus. It is to the presence of these muscles that the higher animals owe the power of retaining for a considerable period the excrementitious matters collected in the bladder and rectum, and of discharging them at intervals, the sphincter muscles being, like those engaged in the process of respiration, mainly, but not entirely, under the control of the will.

Sphinx, a name (wrongly derived from a Greek word signifying the 'strangler'), applied to certain symbolical forms of Egyptian origin, having the body of a lion, and a human or an animal head. Various other combinations of animal forms have been called by this name, although they are rather griffins or chimæras. Human-headed sphinxes have been called androsphinxes; that with the head of a ram, a criosphinx; and that with a hawk's head, a hieracosphinx. Late forms have wings added at the sides; but these seem to have originated with the Babylonians or Assyrians. In the Egyptian hieroglyphs the Sphinx bears the name of *Neb*, or Lord, and *Akar*, or Intelligence, corresponding to the account of Clement that this emblematic figure depicted intellect and force. Others see in it the idea of resurrection, symbolised by the triumph of the dawn over the darkness of night. The idea that it allegorised the overflow of the Nile when the sun was in the constellations Leo and Virgo appears to be unfounded. In Egypt the Sphinx also occurs as the symbolical form of the monarch considered as a conqueror, the head of the reigning king being placed upon a lion's body, the face bearded, with the usual head-dress. Thus used, the Sphinx was generally male; but in the case of female rulers the figure has a female head and the body of a lioness.

The most remarkable Sphinx is the Great Sphinx at Gizeh (Giza), a colossal form hewn out of the natural rock, and lying about a quarter of a mile south-east of the Great Pyramid. It is sculptured out of a spur of the rock itself, to which masonry has been added in certain places to complete the shape, and it measures 172 feet 6 inches long by 56 feet high (Vyse, *Pyramids*, iii. 107). Immediately in front of the breast Caviglia found in 1816 a small naos or chapel, formed of three hieroglyphic

tablets, dedicated to the Sphinx, under the name of Haremkuh, or Harmachis, as the Greek inscriptions found at the same place call it—i.e. Horus on the Horizon. These tablets formed three walls of the chapel; the fourth, in front, had a door in the centre and two couchant lions over it. A

Great Sphinx at Gizeh.

small lion was found on the pavement, and an altar between its fore-paws, apparently for sacrifices offered to it in the time of the Romans. Before the altar was a paved causeway or dromos, leading to a walled staircase of thirty steps, repaired in the reign of M. Aurelius and L. Verus on the 10th May 166 A.D. In the reigns of Severus and his sons, 199–200 A.D., another dromos, in the same line as the first, and a diverging staircase were constructed, while some additions had been made to the parts between the two staircases in the reign of Nero. Votive inscriptions of the Roman period, some as late as the 3d century, were discovered in the walls and constructions; and on the second digit of the left claw of the Sphinx an inscription in pentameter Greek verses, by one Arrian, probably of the time of Severus, was discovered. In addition to these walls of unburnt brick, galleries and shafts were found in the rear of the Sphinx extending northwards. The excavations of M. Mariette in 1852 threw further light on the Sphinx, discovering that it was surrounded by a peribolos or outer wall; and showing that the head only was sculptured; and that the masonry of the belly was supported by a kind of abutment. To the south of the Sphinx Mariette found a dromos which led to a temple of the time of the 4th dynasty, built of huge blocks of alabaster and red granite. In the midst of the great chamber of this temple were found seven diorite statues, five mutilated and two entire, of the monarch Chafra or Chephren, which are fine examples of the oldest Egyptian sculpture. While the dignity and grandeur of the Great Sphinx have often attracted the admiration of travellers (see SCULPTURE), its age has always remained a subject of doubt; but it is generally considered to be a monument of at least the age of the 4th dynasty, or contemporary with the pyramids, though Maspero regards it as anterior even to Menes.

Besides the Great Sphinx, avenues of Sphinxes have been discovered at Sakkarah, forming an approach to the Serapeum of Memphis and elsewhere. Sphinxes of a peculiar type, perhaps of the 12th dynasty or even earlier, have been found at Tanis,

and another of the same age is in the Louvre; while a granite Sphinx, found behind the 'vocal Memnon,' and inscribed with the name of Amenophis III., is at St Petersburg. An avenue of criosphinxes, each about 17 feet long, is still seen at Karnak, and belongs to the time of Amenhotep III., one of the last monarchs of the 18th dynasty. There is also an alabaster Sphinx, probably of Rameses II., found by Petrie at Memphis. This is the next in size to the Great Sphinx. Various small Sphinxes are in the different collections of Europe, but seldom are of any very great antiquity.

The Theban Sphinx of Greek legend, whose myth first appears in Hesiod (*Theog.* 326), is described as having a lion's body, female head, bird's wings, and serpent's tail, ideas probably derived from Phœnician sources. She was said to be the issue of Orthros, the two-headed dog of Geryon, by Chimæra, or of Typhon and Echidna, and was sent from Ethiopia to Thebes by Hera to punish the transgression of Laius, or, according to other accounts, by Dionysus or Ares (see EDIPUS). The Sphinx was a favourite subject of ancient art, and appears in reliefs, on coins of Chios and other towns, and often as a decoration of arms and furniture. In Assyria and Babylonia representations of Sphinxes have been found, and the same are not uncommon on Phœnician works of art.

Sphinx. See HAWK-MOTH.

Sphygmograph. an instrument for indicating changes of tension in the blood in an artery; practically a pulse-recorder. It was invented by Vierordt, and greatly improved in 1863 by Marey of Paris. When the instrument is applied to an artery a moving point traces a record on a band of paper moved by clockwork. A sphygmophone is a sphygmograph combined with a microphone. A sphygmoscope renders the pulsations visible. Dudgeon's sphygmograph is one of the most convenient and best known. The polygraph is a similar instrument by which simultaneous tracings can be taken from several vessels.

Spice Islands. See MOLUCCAS.

Spices (Lat. *species*, 'kinds; in later Latin, kinds of goods, or produce in general; and then the most highly prized kind of goods, the aromatic productions of the East), aromatic and pungent vegetable substances used as condiments and for flavouring food. They are almost exclusively the productions of tropical countries. In ancient times and throughout the middle ages all the spices known in Europe were brought from the East; and Arabia was regarded as the land of spices, but rather because they came through it or were brought by its merchants than because they were produced in it, for they were really derived from the farther east. They owe their aroma and pungency chiefly to essential oils which they contain. They are yielded by different parts of plants; some, as pepper, cayenne pepper, pimento, nutmeg, mace, and vanilla, being the fruit or particular parts of the fruit; whilst some, as ginger, are the root stock; and others, as cinnamon and cassia, are the bark. Tropical America produces some of the spices, being the native region of cayenne pepper, pimento, and vanilla; but the greater number are from the East.

Spicheren, or SPEICHERN, a village on the frontiers of Prussia and Lorraine, 2 miles S. of Saarbrück. Here on 6th August 1870 was fought a bloody

battle between the French and Germans, in which the former were defeated. See FRANCE, and the work on the battle by Major Henderson (1892).

Spider-crab. See CRAB.

Spider-fly (*Ornithomyia*), a genus of dipterous insects closely allied to the Forest-fly, but parasitic on birds, not on mammals. Thus, *O. avicularia* frequently infests the common fowl, the blackcock, and other birds in Britain. It is greenish-yellow, with smoke-coloured wings.

Spider-monkey, a name given to an American genus of Monkeys (q.v.), Ateles. These monkeys have no thumb, or it is rudimentary. They occur only in South America, Mexico, and Central America. The popular name has been given to them on account of their long, slender limbs. Like

Spider-monkey (*Ateles bartlettii*).

other New-World monkeys (Platyrrhini), they have a prehensile tail, and are naturally purely arboreal in habit. Although denizens of the tropical forests of the New World, they can, like the tropical apes of the Old World, endure a very considerable amount of cold. One species, *A. vellerosus*, lives in large companies in forests at a height of 7000 feet in Mexico. The Coaita is *A. paniscus*. About ten species of the genus are known.

Spiders (*Araneida*) form an order within the heterogeneous class Arachnida. The name, which points to an older form, *spunther*, refers to the well known spinning powers which these animals so cleverly exercise. They are found almost everywhere upon the earth, especially in warm countries, and are of much importance in checking the multiplication of insects. A few tropical forms, notably the bird-catching spiders, exceed two inches in length of body, but the majority measure only some fraction of an inch.

Structure and Functions.—The body is divided into two distinct parts—an unsegmented cephalothorax, bearing six pairs of appendages, and a soft unsegmented abdomen, at the end of which are the spinnerets. On the skin there are hairs of various kinds, some being specialised as sensitive structures. The colours, which are often very brilliant, are due in part to pigments, in part to the way in which the light is reflected from the hairs and skin. They vary with age and sex, with food and environment, and, as we shall see, are often of importance in courtship and in protective adaptations. Soon after the young spider is hatched it casts its cuticle, and this moulting is repeated at intervals until the full size is reached. It is prob-

able that the Attidae moult from seven to eleven times before reaching maturity. As this moulting proceeds, the colour, which in young spiders is generally bright yellow or green, whitish or livid, gradually assumes tints and markings characteristic of the species.

There are six pairs of appendages: (1) the clawed chelicere or falcex, of which the last joint works against the second last and contains a poison-gland; (2) the leg-like pedipalps, the terminal joint of which is modified in the male for copulatory purposes; (3-6) four pairs of walking-legs, of which the foremost pair are much used as feelers. The embryo has four pairs of abdominal legs which abort. Near the anus are situated two, three, or four pairs of closely approximated spinnerets, and on each of these there are numerous 'spinning-spools,' out of which oozes the viscid fluid which hardens into the silken thread. A figure is given of the foot of the hindmost leg in the Garden Spider, showing the claws and spines, which are of use in drawing out the silken secretion. Among other external characters are the simple eyes, of which a variable number, most frequently eight, occur on the head; the openings or stigmata of the respiratory sacs or tubes; the opening of the reproductive ducts between the anterior stigmata; and (in the female) the adjacent but separate aperture or apertures of the receptacula seminis.

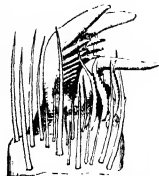

Fig. 1.—Foot of Garden Spider.

The nervous system conforms to the usual Arthropod type, consisting of a dorsal brain, a ring round the gullet, and a ventral nerve-cord; but the ventral ganglia are concentrated in a single ganglionic mass in the thorax, giving off nerves to the limbs and other parts.

As regards the senses of spiders, it seems that few have much power of precise vision. Some discern rapid movements of objects, but seem unable to see their cocoon though it be but a few inches off. The hunting Saltiguides, however, have been observed to stalk prey from a distance of 10 inches, but that this is regarded as exceptional shows how limited the ordinary power of vision is believed to be. In many cases it has been experimentally proved that spiders exhibit an apparent preference (perhaps dependent on sexual associations) for certain colours, and it is certain that the males of some kinds (e.g. Attidae) display their bright colours before their desired mates. The limited nature of visual power is in great part compensated for by the exquisite delicacy of the sense of touch, for the lurking spinner feels rather than sees the insect tangled in its snare or web. Vibrations such as those caused by the whizzing of insects' wings or by a tuning-fork are propagated along the taut lines of the web and interpreted by the spider. According to some observers, the courtship is sometimes conducted in this telephonic fashion. This tactile sensitiveness seems to be in great part diffused over the body, but the hairs towards the ends of the legs are specially sensitive. We know little with regard to the sense of hearing in spiders. That some males, e.g. of Theridium and Mygale, are able to produce a stridulating noise, suggests that their mates can hear, but the evidence is not conclusive. Nor are the numerous accounts of spiders which descend chandeliers and the like to listen to music, for spiders often do this when there is no music, and are especially likely to do this on an evening, and it is difficult to abstract the influence of vibrations other than those of sound-waves. Many, however, believe that spiders

really hear, and it may be that careful experiments will prove that what are described as 'auditory hairs' on the palps and legs are really such. The sense of smell seems to be slight, though marked for certain strongly-scented substances, and there is a sensory structure, perhaps olfactory or gustatory, on the basal joint of the pedipalps.

All spiders are predaceous and feed on insects, which they entangle in their snares and webs, or stalk, or catch after patient lurking. In most cases they kill their prey with their poisonous fangs. The mouth is small, and behind the gullet there is a powerful suctional region which acts as a suction-pump. From the mid-gut five paired outgrowths extend into the bases of the pedipalps and legs. There are also large tubular digestive outgrowths, and two excretory Malpighian tubes grow out from the hindgut. The heart lies dorsally in the abdomen, and has three chambers with three pairs of valved openings. In one set (Tetrapneumones, e.g. the bird-catching Mygalæ; see BIRD-CATCHING SPIDER) there are four pulmonary sacs like those of the scorpion; in the great majority (Dipneumones) there are two pulmonary sacs and two main tracheal tubes.

The sexes are separate except in a few casual hermaphrodites, and the males are often fewer in number, always smaller in size, and usually more brightly coloured than the females. In most cases, as we shall afterwards see, the courtship is elaborate, and is often attended with considerable danger to the males. The fertilised egg segments peripherally, like that of insects, around a central core of yolk. A cocoon is usually formed around the eggs, and this is hidden or carried about by the female, who exhibits much maternal solicitude.

The fertility of spiders varies in different species within wide limits. Thus, as Mrs Peckham notes, one species may lay 800 or 1000 eggs, while another, equally common, lays only fifty. In the family Epeiridae *Argiope caphura* lays 500 to 2200 eggs, while *Tetragnatha laboriosa* lays only 34; in the family Attidae *Phidippus morsitans* lays about 180 eggs, while *Synageles pucata* lays only three. While the rate of multiplication is immediately dependent on the constitution of the different species, it also bears some relation to the rate of mortality, or, what comes almost to the same thing, to the efficiency of the protective adaptations by which spiders are saved from their enemies. Those with a low birth-rate are usually protected very efficiently, and have consequently a low rate of mortality.

In many cases female spiders are savage and quarrelsome, fighting with one another, and frequently destroying the smaller males when these offer them amatory attentions. 'Ridiculously small and weak in build, the males of many species can only conduct the rites of marriage with their enormous and voracious brides by a process of active manœuvring, which, if unsuccessful, is certain to cost them their lives.' In a great number of cases, e.g. in at least two-fifths of all the species of Attidae, the males are more brilliantly coloured than the females, and that this is in part related to sexual selection is rendered almost certain by the observations of Professor and Mrs Peckham, who often worked four or five hours a day for a week in getting a fair idea of the habits of a single species. They describe among many species of Attidae the manner of the wooing, the cautious circling dances of the ardent males, the strange attitudes by which they display their charms of colour, the occasional wooing by vibrations of the web-lines, the captious irritability of the females, who often bring the courtship to a tragic end, the quarrelsome of rival males in presence of the females. 'The males vie with each other

in making an elaborate display, not only of their grace and agility but also of their beauty, before the females, who, after attentively watching the dances and tournaments which have been executed for their gratification, select for their mates the males which they find most pleasing' (see SEXUAL SELECTION).

Spinning-work.—On each of the spinnerets—of which in the majority there are six—there are numerous, usually sixty to seventy, 'spinning-spoils,' out of which there flows a viscid secretion formed in the numerous internal glands. The resultant thread into which the secretion hardens, though of a delicacy hardly rivalled except by quartz fibres, is from the nature of its origin a complex structure. Its texture is not always the same; it may be covered with minute adhesive beads, or be stronger and unheaded, or very light and filmy as in gossamer. In some spiders there is a special chitinous plate—called the cribellum—lying in front of the spinnerets and perforated by the ducts of numerous glands. Its presence is correlated with that of the calanistrum, a single or double row of long wavy hairs on the dorsal aspect of the second last tarsal joint of the fourth pair of walking-legs. One of the calanistrum is rapidly vibrated over the cribellum, and draws out the secretion from the glands in the form of threads, used to strengthen the web, to assist in forming the cocoon for the eggs, and sometimes perhaps in making a domicile.

The webs of spiders vary as much as do the nests of birds, but as a single example of their making we may take that of the Common Garden Orb-weaver

(*Epeira daedala*). The spinner first lays down a number of firm foundation-lines, which may be disposed 'by hand' if the situation admits of this, but are more frequently blown fortuitously by air-currents. Having secured a number of these foundation-lines enclosing the area for the web, the spider forms the radii which intersect in the centre. This done, she begins from the centre and stepping outwards in a wide spiral lays down the spiral scaffolding. Finally, beginning at the circumference and working inwards, the spider lays down the delicate viscid spirals on which the efficiency of the web depends. The primary spirals simply form a scaffolding, and are undone, in fact eaten up, as they are replaced. But the web of the garden spider is a comparatively simple case; we have to distinguish 'orb-webs,' 'ribboned orbs,' 'composite snares and sectional orbs,' 'horizontal snares and domed orbs,' 'unheaded orbs and spring snares,' and so on, as Dr McCook, in his incomparable work on American spiders, has pointed out.

Fig. 2.—*Astia vittata*, male 'displaying his charms.'

(After G. W. and E. G. Peckham.)

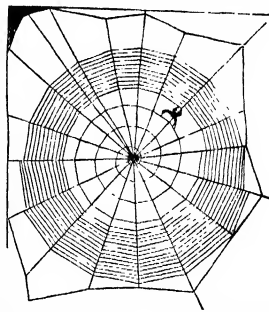

Fig. 3.—Garden Spider spinning her web.

(From 'Riverside' Natural History.)

No structures made by animals—not even the nests of birds, the homes of bees, the hills of the Termites—are more marvellous than the webs and snares of spiders. The framework is so delicate yet so effectively firm, so clever in its construction, so sensitive, we may almost say, in its mechanism, that we must rank it highest among works of instinctive art. Instinctive, for each species of weaver has its characteristic web, and there is no reason to suppose that the art of making this is the result of education. Yet the mode of construction is not rigidly fixed, but varies a little according to the site, according to the wind, and even, it is said, in relation to the abundance of insects in the neighbourhood. We see the strength of the web when it remains unbroken in the wind, and when it is laden with drops of dew, but sometimes it is much stronger than such sights suggest. Mosely tells how Willemoes Salm on the *Challenger* expedition found a Glossy Starling (*Calonotus metallica*) hopelessly entangled in a spider's web, and other naturalists relate the same of humming-birds and other small creatures. Thus a snake, nine inches long, has been found hanging in a web; and Dr McCook, whose carefulness as an observer is worthy of all praise, relates how a young living mouse was in some manner secretly entangled in the snare of a spider, how the spinner, by means of silken threads two or three feet long, hoisted the mouse up four inches, and how the mouse after living for ten hours at length succumbed. A spider three-quarters of an inch in length has been seen to land a fish about three inches in length, but perhaps the raising of a mouse in a web is more wonderful. A. I. Wallace and other exploring naturalists also tell of spider-webs strong enough to be a serious obstacle to travellers in the woods, and in other reports fancy has magnified this strength tenfold. As to the intelligence involved in modifying the web in various conditions it is not easy to form an accurate estimate. On a long hedge we may see scores of webs disposed so as best to stand the stress of the prevailing wind, but we must remember that the foundation-lines of the web are in most cases wind-blown. Often in the geometric webs there are interesting irregularities which show that equal precision is not always attained. On the other hand fractured snares are sometimes mended by skillfully disposed tresses. Many observers have described cases where small stones were found hung from the web, as if to weight them against the force of the wind. But McCook maintains, and we would agree with him, that it is most likely that these stones have been raised from off the ground by the shrinkage of the web, and that the alleged advantage—which, if foreseen, involves a complex inference—is simply accidental.

The threads which the spiders spin are used not only in fashioning webs and snares, but in many different ways. Behind them, as they move where a footing is insecure, there trails a drag-line, perhaps the rudiment of all their weaving, and this is of special use when they drop from a height. Jonathan Edwards long ago (1716) observed that spiders in order to cross an unbridged gap will form a sort of swinging basket, and he also noticed their exceedingly strange habit of ballooning. Raising themselves on tiptoe and with upturned abdomen on some point of vantage, they allow long threads of gossamer to float out in the air until these acquire sufficient momentum to carry the spider aloft. In this way they have been known to cross considerable sheets of water. 'To this mode of diversion young spiders of several families are very much addicted, especially in the fine days of autumn. Sometimes the flying threads are excessively numerous, and on their descent cover every-

thing; they are particularly striking on hedges, and constitute, at all events, one of the causes of the phenomenon well known in the country as 'gossamer.' And again, the threads may help to form the cocoon for the eggs, or may be used to bind leaf to leaf and form a well-hidden nest.

Enemies and Protective Adaptations.—While spiders are the fatal enemies of many insects, they are in turn frequent victims. To feed the hungry maw of a stronger, more skilful, or more fortunate fellow Araneid; to be paralysed and entombed within a clay sarcophagus by a mother wasp, and serve as food for a growing waspling worm (see *SPHEX*); to be snapped up as a delicate titbit by birds, toads, and other creatures—these are some of the ways in which the spider meets its doom. Among birds the chief enemies of spiders are the humming-birds, among insects the wasps. The ichneumon flies often lay their eggs—with destructive results—in the cocoons of spiders. Small monkeys prey upon spiders a good deal, and so do some insectivorous mammals. Between different kinds of hunting and running spiders there is much keen warfare.

Many spiders hide in crevices or in bivouacs of leaves which they roll up or bind together. McCook describes the nest of the Purse web Spider (*Atypus abbotii*), a purse-shaped tube attached to the bark of trees, with the outer surface dark and covered with sand. The nests of the trap-door spiders have lids which fit accurately, and are covered with moss, earth, and lichen; in fact the nests of a great number of species believed to be trap-door spiders have never been found. In many cases the vibratory sensitiveness of the web is such that an approaching enemy finds the spider forewarned. When *Argiope cophiaris* has not time to drop from her web to the ground, 'she makes use of another power—she will render herself invisible. The web begins to sway backward and forward; the rapidity of the motion increases; the outlines become indistinct, and within a few seconds of the first movement spider, web, and all have vanished from sight! Others, such as *Pholcus atlanticus*, hang by the legs, and whirl the body rapidly with the same bewildering result.' Herbert Smith suggests that the sideways movement of the *Latreignidae* has a protective value, since the enemies are likely to allow for a forward movement of their prey. Many Epeiridae and other spiders drop to the ground when danger threatens, and remain motionless on a surface which they often resemble in colour. McCook seems inclined to regard this death-feint as a trick, not as fear paralysis or catalepsy. The cocoons are hidden in crevices, or covered with web and debris, or carried about by the mother—sometimes attached to the abdomen, sometimes in the jaws. For further examples of the thousands of protective habits, see the works of the Peckhams and Dr McCook.

Often the forms and colours of spiders have a protective resemblance to pieces of plants or to dead things. The species of *Uloborus* are like small pieces of bark; *Hyptioides cavatus* resembles a bit of dirt or the ends of the dead pine branches among which it lives; *Cyrtophora conica* is hardly distinguishable from the pieces

Fig. 4.—*Cyrtophris mitralis* on a branch (after E. G. Peckham).

of light rubbish which it accumulates in its web; *Cyrtophris mitralis* resembles a woody knot on the branch on which it rests; *Thomisus foka*, a species much dreaded in Madagascar, has a very strange,

crab-like form, and resembles in colour and general appearance the fruit of *Hymenaea verrucosa*, a tree common in the forests where this spider is found; *Drapetisca socialis* is very like the bark of birches and other trees on which it lives; among the

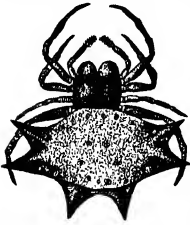

Fig. 5.
Gasteracantha rufospinosa,
female, mag. 2½ diameters.
(After E. G. Peckham.)

Lycosidae there are scores of dull-coloured species that live on the ground; Dr McCook describes one form which has a tint like that of the water upon which it is constantly found; about a dozen species which live on leaves are recorded as protectively green; many Thomisidae are coloured like the flowers on which they await their victims; *Ornithoscutoides decipiens*, first described by Forbes, is, as its name suggests, most deceptively like bird-excrement, so that the discoverer actually plucked the leaf on which the spider was resting, and looked at it for some moments before he discerned his captive. In short, what Wallace said about the leaf-like butterfly is often true of spiders: 'Size, colour, form, markings, and habits all combine to produce a disguise which may be said to be absolutely perfect.'

Again, there are spiders which are rendered inedible by an armature of spines and plates, and many of these (e.g. some *Gasteracanthidae*) are very brilliantly coloured. It is possible that their conspicuousness impresses their enemies with the fact that they are better left alone.

Lastly, there are spiders which exhibit a protective mimicry of animal forms. 'Spiders most commonly mimic ants,' E. G. Peckham says; 'but we hear also of their imitating beetles, snail-shells, ichneumon and horse flies. There is also a curious Madagascan species which looks exactly like a little scorpion, the resemblance being heightened by the habit of curving its flexible tail up over its back when irritated.' Nearly all the species of *Coccorhynchus* and *Homalotatus* resemble beetles; *Cyrtarachne* is like a snail-shell; *Synagles picata* and *Synemosyna formica* are good examples of those which have a mimetic likeness to ants.

Classification.—Spiders of the Bird-catcher (*Mygale*) type differ from all the others in having four pulmonary sacs (*Tetrapneumones*). The *Dipneumones*, which form the vast majority, including several thousand species, are conveniently classified according to their habits whether sedentary or wanderers, and according to their spinning-work, this physiological classification being also justified anatomically. Another fact of some importance is the presence or absence of a cribellum. Thus we distinguish

'Sedentary'	Sub-order—TETRAPNEUMONES.	Tribes I.—Territorialia: Tunnel-weavers.
		Sub-order—DIPNEUMONS.
	Tribes II.—Tubellaria: Tube-weavers, including Eribellata and Cribellata.	Tribes III.—Retellaria: Line-weavers.
		Tribes IV.—Orbicularia: Orb-weavers, including Eribellata and Cribellata.
		Tribes V.—Laterigradae.
	'Wanderers'	Tribes VI.—Citigradae.
		Tribes VII.—Saltigradae.

Numerous extinct species of spiders have been obtained from Tertiary deposits, especially from amber. The oldest known form (*Protolycosa*) occurs in Carboniferous strata.

British Species.—Among the British species the following may be noted: The Common Garden

Spider (*Epeira diadema*), and other species of this genus; the House-spiders (*Tegenaria domestica* and *T. civilis*); *Agelena labyrinthica*, which makes large cobwebs, very abundant on heaths; the Water Spider (*Argyroneta aquatica*), which inflates its sub-aquatic dome-shaped web with air brought from the surface entangled among the hairs of the spider's body; the Green Crab-spider (*Sparassus smaragdulus*), whose young are fond of ballooning in autumn evenings; a few Wolf-spiders, such as *Lycosa piratica* and *Dolomedes fimbriatus*; *Salticus scenicus*, exceedingly common on walls and fences, and *Atypus sulzeri*, the only British representative of the Trap-door Spiders (see Systematic List: P. Cambridge, *Proc. Linn. Soc.*, xxx. 1875).

Fig. 6.—The Garden Spider
(*Epeira diadema*).

Relations to Man.—The wide-spread prejudice against spiders is not scientifically justifiable. We must admire their dexterity, their instinctive aptitudes, their intelligence, the beauty of their architecture, the elaborateness of their courtship (tragic as it sometimes is for the suitor), and their maternal care. Although there are countless tales of 'black spiders,' rarely preserved for identification, which are alleged to have given dangerously poisonous bites, this is not true except in regard to the famous Tarantula (*Lycosa tarantula*), and even the effects of its bite have been grossly exaggerated both by evil intention and credulous superstition. Of a not uncommon line-weaver (*Lathrodictus oculatus*), which has a very bad reputation as a venomous biter, one of the authorities on spiders says that he repeatedly allowed himself to be bitten and suffered no inconvenience. In fact, if we except the Tarantula, there are few spiders more dreadful than are fleas. In old medical practice a spider was sometimes applied to the wrist in cases of fever, and another custom of applying the web to staunch bleeding is still practised by schoolboys, who are happily ignorant of antiseptic precautions. The great value of spiders is the obvious one that they destroy so many insects; thus, McCook counted thirty-six mosquitoes on a single web.

Spielberg. See BRUNN.

Spielhagen, FRIEDRICH, German novelist, was born at Magdeburg on 24th February 1829, but passed all his youth at Stralsund. From the

gymnasium there he proceeded in 1847 to the universities successively of Bonn, Berlin, and Greifswald, afterwards settling at Leipzig in 1854 as a docent, at Hanover in 1859, and at Berlin in 1862, in the last two places till 1884 as a newspaper editor. His works, of which several have been translated into English, are some fifty in number, and include (besides poems, dramas, books of travel, translations, and short stories) *Problematische Naturen* (1860), *Durch Nacht zum Licht* (1861), *Die von Hohenstein* (1863), *In Reih und Glied* (1866), *Hammer und Amboss* (1868), *Sturmflut* (1876), *Uhlenkrons, Quisisama, Faustulus* (1897), *Herrin* (1899), and *Freigeboren* (1900). Mostly "novels with a purpose," dealing with burning questions of the day, his best work has exceptional power and charm, in spite sometimes of portentious length; the sea interest is rare in German fiction. He died 25th February 1911. He published an autobiography in 1890 (2 vols.), and there are studies by Karpeles (1889) and Henning (1910).

Spigelia, a genus of plants of the family Loganiaceae, having a calyx glandular inside, a long slender valvate corolla, long filaments, and a capsule of two *coeci*, splitting around at the base. *S. marilandica*, often called Worm Ginseng and Carolina Pink, is a native of the southern United States, a perennial plant with a simple quadrangular stem. The root (Pink Root) is purgative, narcotic, and poisonous, but is a powerful vermifuge, and is very commonly employed in the United States. *S. Anthelmintica*, an annual, native of tropical America, with very small purplish flowers, in spike-like racemes, possesses similar properties. The efficacy of both is, however, impaired by keeping; and they are apt to produce unpleasant symptoms when used as medicines. Other species are also known as poisons.

Spike, in Botany, that kind of inflorescence in which sessile flowers, or flowers having very short stalks, are arranged around an axis, as in the greater plantain, common vervain, common lavender, and some species of sedge. In rye, wheat, barley, dandelion, and many other grasses there is a sort of compound spike—i.e. the flowers or fruits are arranged together in spikelets upon short stalks, which again surround the top of the culm in the form of a spike. The catkin, the spadix, and the cone may be regarded as varieties of the spike.

Spikenard, or NARD (Gr. *Nardos*), a perfume highly prized by the ancients, and used both in baths and at feasts. It was brought from India, and was very costly. The plant which produces it is the *Nardostachys Jatamansi*, a small plant of the family Valerianaceae, a native of the Himalaya, found at least as far south as the Deccan. The odour is not, however, generally agreeable to Europeans. Spikenard is popularly believed to have the power of promoting the growth and blackness of the hair, and to be an antidote for poisons. It is now more used medicinally than as a perfume. The aromatic hairy tap-root, which is from 3 to 12 inches long, sends up many stems with little spikes of purple flowers, which have four stamens. The name spikenard was given by the ancients to many perfumes used as substitutes for the true or Indian spikenard, some of which were derived from the roots of plants of the same family, the kind called Gallic or Celtic spikenard from those of *Valeriana celtica* and *V. salicina*, which are still used in the East for perfuming baths, and that called Cretan spikenard from those of *V. tuberosa* and *V. Phu*. All of these grow on the Alps and other mountains of the south of Europe, and the peasantry of Styria and Carinthia collect them from rocks on the borders

of perpetual snow. They are tied in bundles, and sold at a very low price to merchants, who sell them at a great profit in Turkey and Egypt, from which a proportion is transmitted even to India.

Spiking is the operation of quickly rendering a muzzle-loading gun useless, resorted to by troops compelled to abandon their own pieces or unable to remove those of the enemy which they have captured. The process consists in driving a cast-iron spike into the vent or touch-hole and then breaking it off short with a hammer. A spiking party of artillerymen always accompanied a storming party. To render a spiked gun again serviceable it was generally necessary to drill a fresh vent. Breech-loading guns are best rendered temporarily unserviceable by removing part of the breech mechanism.

Spillsby, a market-town of Lincolnshire, 19 miles by rail NE. of Boston, stands on the edge of the Wolds. The church contains interesting monuments of the Willoughby family (1348-1610), and the market-place has a bronze statue of Sir John Franklin, a native of the town.

Spinach, or SPINAGE (*Spinacia*), a genus of herbaceous plants of the family Chenopodiaceae; dioecious, the male flowers consisting of a four-parted perianth, and four stamens; the female, of a two to three cleft perianth, and an ovary with four styles; the perianth hardening around the fruit as it ripens; the fruit an acheneium. Common Spinach, or Garden Spinach (*S. oleracea*), is in

Common Garden Spinach (*Spinacia oleracea*).

general cultivation for the sake of its young leaves, which are a favourite and wholesome vegetable, prepared either by boiling or by frying with a little butter. Two very distinct varieties are cultivated—Prickly Spinach, which has the leaves somewhat triangular and arrow-headed, and the fruit rough with prickly-like projections; and Smooth Spinach, or Round Spinach (*S. glabra* of some botanists), with the leaves more round and blunt, and the fruit smooth. Spinach is an annual. Its stem rises to the height of from 2 to 4 feet; the male flowers are in long spikes, the female in clusters close to the stem. After the stem begins to be developed the leaves become bitter and unfit for use. This bitterness appears also at an earlier period in dry weather or in poor soil; and the more luxuriantly spinach grows the better it is. It is sown in spring, and is ready for use in a very short time; or it is sown in autumn, thinned out, and used early in spring. The smooth spinach is very generally preferred for the former purpose, and the prickly kind for the latter; but a somewhat intermediate variety called Flanders Spinach, in the seed trade named Viroffley Spinach, is now

often used for both, being particularly esteemed for the large size of its leaves. The native country of spinach is not well known, but is believed to be some part of Asia, as the plant was introduced by the Arabs into Spain, and thence diffused over Europe. Another species (*S. tetrandra*) is cultivated and much esteemed in India. The name spinach is also given to a number of other plants of very different botanical characters, but the same bland and nutritious qualities, and used in the same way. New Zealand Spinach is *Tetragonia expansa*, a plant of the Aizoaceae, a trailing, succulent annual, spreading widely over the surface of the ground, and producing a great abundance of stalked ovate-rhomboid leaves. The young stems and leaves of this plant are much used in New Zealand, and have now come into very general use also in other parts of the world as a kind of spinach. It is cultivated in the middle and south of Europe and in Britain, succeeding well even in Scotland with the slightest aid of a hotbed in spring, and is found particularly useful in light dry soils, in which in summer it is difficult to maintain supplies of the common spinach. Patience Dock, or Garden Patience (*Rumex Patience*: see DOCK), is called in Germany English Spinach, and was formerly much cultivated in England, but is now neglected.

Spinal Column and Spinal Cord. The spine or spinal column is the most important and characteristic part of the Skeleton (q.v.) of the highest division of the animal kingdom. It is composed of a series of bones placed one above, or in front of another, and called vertebrae; and hence these animals, having this distinguishing characteristic in common, are all included in the term *Vertebrates*. The vertebrae vary greatly in number in different animals, and even in members of the same class, and the number bears no apparent relation to the other organs of the animal. Moreover, in their shape they differ extremely even in different parts of the same spine, in accordance with their special functions. In man the number of vertebrae which collectively form the spinal column is 7 in the neck (cervical vertebrae), 12 in the back (dorsal vertebrae), 5 in the loins (lumbar vertebrae), all of which are capable of being detached from one another, and are termed *true* vertebrae; and 5 vertebrae which ossify together after birth and form the sacrum, and 4 or 5 similarly united forming the termination of the column, and constituting the bone called the coccyx, which are known as *false* vertebrae. However long or short the neck may be, every mammal has 7 cervical vertebrae, excepting the three-toed sloth, which has 9, and the sea-cow, which has 6. In the other regions of the spine no such uniformity exists. Each vertebra is attached to the two between which it lies by numerous strong and more or less elastic ligaments, and between each pair of vertebrae there is interposed a lenticular disk of fibro-cartilage, which acts as a buffer. By these arrangements the spinal column is rendered highly elastic, the communication of jars or shocks is prevented, and a very considerable general range of movement permitted, although the motion between any two adjacent vertebrae is slight. The elasticity of the column is further increased by the component vertebrae being arranged in curves instead of being placed perpendicularly. The curves should be exactly in the antero-posterior direction, any well-marked lateral deviation from the perpendicular being abnormal; but a very slight lateral curvature with the convexity to the right may often be detected in the upper and middle parts of the back, and is supposed to be dependent on the more frequent use and greater strength of the right arm as compared with the left. From their position they are termed

the cervical, dorsal, lumbar, and sacral curves. The dorsal and sacral curves have their concavities in front, and thus enlarge the spaces in which the thoracic and pelvic viscera are contained; the two other curves are convex anteriorly, and thus afford support to the parts above them. The upper three curves are so arranged that their cords are in the same vertical line in the erect position of the body, and this vertical line corresponds with the line of gravity of the head. The cause of these curves is to be sought for in the shape of the vertebral bodies, in that of the intervertebral substance, and in the individual's attitude or gait. They enable the spine to bear a greater vertical weight; it is calculated that nine times as great a vertical force is required to bend it as if it had been straight; and they facilitate the movements of the body, especially in the act of running. Similar curves are seen in the spine of other mammals (see ANTHROPOID APES), though the degree of curvature is liable to great variation. The lumbar curve, which has especial reference to the erect position, is always much less marked than in man, and is much less pronounced among primitive races than among Europeans. Further, all human beings acquire the cervical and lumbar curves subsequent to birth, whereas the dorsal and sacral curves are present at birth.

The vertebral canal formed by the apposition of the spinal foramina or neural arches, and containing and protecting the spinal cord, varies in its size at different parts of the column. It is largest in its antero-posterior diameter in the neck and loins (measuring at the last lumbar vertebra $\frac{3}{4}$ of an inch), where the antero-posterior movements of the spine are greatest, and where the cord is least closely attached to the vertebrae; while in its lateral diameter it is greatest at the atlas, where it measures nearly an inch and a half. A transverse section of the canal is nearly circular through the greater part of the back. The intervertebral foramina through which the nerves emerge vary in shape and position in different parts, but are always of sufficient size to prevent injurious pressure on the nerves during movement of the spine; and in the dorsal region, which is the ordinary seat of angular curvature, the nerves are so protected by bony arches that they may escape injury, even when the bodies of several dorsal vertebrae have been destroyed by ulceration.

The *spinal cord*, which occupies the whole extent of the vertebral canal in the early months of fetal life, extends in the adult from the foramen mag-

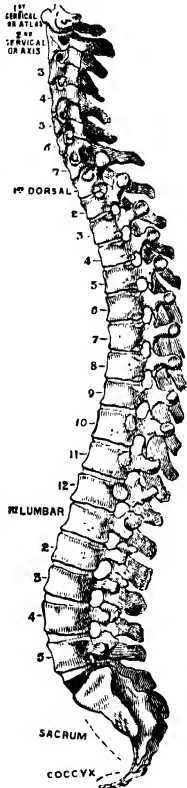

Fig 1.—Spinal Column

num to the lower edge of the first lumbar vertebra, and has an average length of 45 cm. Below this point it is continued as a narrow thread containing little nervous matter, the *filum terminale*. The cord is, like the brain, encased in a triple sheath of membranes, the pia, arachnoid, and dura mater, the last two of which are less closely opposed to the cord and the vertebral column than they are to the brain and the cranium. The cord is a somewhat flattened cylinder or column of a whitish colour. It is divided into two lateral halves by an anterior median fissure and a posterior median septum. The former is less deep but wider than the latter, which is merely a process of pia mater. From each side of the cord thirty-one pairs of spinal nerves arise, each by an anterior and a posterior root (see NERVOUS SYSTEM). The cord is not of uniform circumference throughout. There is a slight thickening where the brachial nerves, and another where the lumbar nerves, arise. These are termed the brachial or cervical and lumbar enlargements respectively. The nerve roots in the cervical and dorsal regions pass nearly

are of the multipolar type. They send a well-marked axis cylinder process into the anterior nerve root, and by their other processes are associated with fibres which descend from the cerebrum and from the posterior roots and other sources. In the posterior horn the nerve cells are mostly smaller, with short axons which end in the adjoining gray matter of the lateral and anterior horns. In the lateral horn, the cells are small and elongated, and form the *intermedio-lateral tract*; they are connected with the sympathetic system.

The white matter of the cord is composed of nerve fibres, united by a small amount of connective tissue. The fibres have mostly a longitudinal direction, with the exception of a small strand which crosses from one side to the other at the bottom of the anterior median fissure—the anterior white commissure. Each half of the cord is divided by the anterior and posterior roots into three columns, named anterior, lateral, and posterior. Though these look almost exactly alike, both to the naked eye and under the microscope, they can be divided into groups by the 'embryological' and 'degenerative' methods. The former is based on the fact that certain groups of nerve fibres obtain their myelin sheaths before others; the latter depends on the fact that if a nerve fibre is separated from its nerve cell, the separated part wastes or degenerates, while the part which is united to the nerve cell does not degenerate, although the nerve cell itself undergoes a degenerative change known as 'chromatolysis.' An injury to the spinal cord will thus show an *ascending degeneration* above the injury of sensory fibres whose cells of origin lie below the lesion, and a *descending degeneration* of motor fibres whose cells of origin lie above the lesion. The principal ascending tracts are—(1) The *postero-median* and *postero-lateral* tracts. These lie in the posterior column and arise from cells in the posterior root ganglia. They pass upwards on the same side of the cord to the medulla oblongata, where they terminate in two large nuclei known as the *nucleus gracilis* and *nucleus cuneatus*. A second neurone, termed the *mesial fillet*, carries the impulses after decussating upwards to the optic thalamus of the opposite side. The connection with the post-Rolandic cortex is not yet identified. These fibres carry sensory impulses from the sensory end-organs to the cerebrum. (2) The *direct cerebellar tract* of Flechsig and the *antero-lateral ascending tract* of Gowers were once thought to be distinct, but are now known to be one tract (spino-cerebellar tract). They arise from the cells of Clarke's Column, a nucleus of large nerve cells lying at the base of the posterior horn, and enter the cerebellum without decussating by the inferior peduncle, except a few fibres which pass upwards and enter by the superior peduncle. (3) Numerous other smaller tracts pass upwards from the spinal cord to other parts of the brain stem. The principal descending tracts are: (1) The *crossed pyramidal* or *cerebro-spinal tract*, which arises from the Betz cells in the motor area of the cortex and passes downwards to decussate in the medulla and terminate in the spinal cord, where a connection is established with the motor

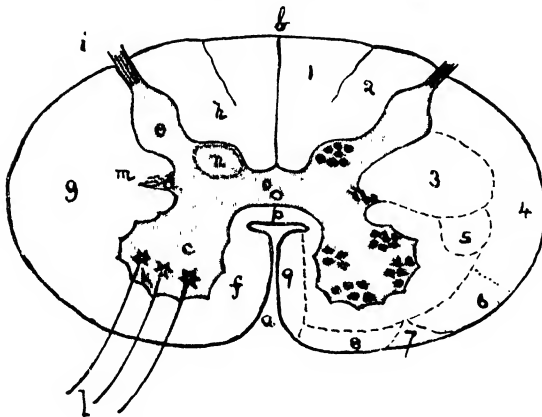

Fig. 2.—Diagrammatic Transverse Section of Spinal Cord.

a, anterior median fissure; b, posterior median septum; c, d, e, anterior, lateral, and posterior horns of gray matter; f, g, h, anterior, lateral, and posterior columns of white matter; i, posterior roots; j, k, anterior horn nerve cells; l, anterior nerve roots; m, intermedio-lateral tract; n, Clarke's column; o, central canal; p, anterior commissure; q, postero-median tract (of Goll); r, postero-lateral tract (of Burdach); s, crossed pyramidal tract; t, direct cerebellar tract (of Flechsig); u, pre-pyramidal tract (of Monakow); v, antero-lateral ascending tract (of Gowers); w, bundle of Helweg; x, antero-lateral descending tract (of Lowenthal); y, direct pyramidal tract.

transversely outwards through the intervertebral foramina; but the lumbar and sacral nerves are directed downwards to attain their points of exit, in such a manner as to obtain the name of *Cauda Equina*.

The cord is seen to be composed of white and gray matter. On a transverse section the gray matter is found in the centre to present the appearance of a double crescent, concave outwards, with a commissural band between the two sides, so that the whole somewhat resembles the letter H. In the gray commissure is the *central canal*, which extends throughout the whole length of the cord and becomes continuous above with the fourth ventricle. The gray matter is divided into an anterior, a lateral, and a posterior horn. It is composed of a basis of connective tissue with a fine felt-work of nerve fibres and nerve cells. In the anterior horn, which becomes specially developed in the brachial and lumbar enlargements, the cells

are of the multipolar type. They send a well-marked axis cylinder process into the anterior nerve root, and by their other processes are associated with fibres which descend from the cerebrum and from the posterior roots and other sources. In the posterior horn the nerve cells are mostly smaller, with short axons which end in the adjoining gray matter of the lateral and anterior horns. In the lateral horn, the cells are small and elongated, and form the *intermedio-lateral tract*; they are connected with the sympathetic system.

cells in the opposite anterior horn. A few fibres do not decussate, and form the *direct pyramidal tracts* which only pass as far down as the cervical region and finally decussate in the anterior commissure. (2) The *pre-pyramidal* or *rubro-spinal tract* arises in the red nucleus in the mid-brain, decussates close to its origin, and ends in the gray matter of the spinal cord. Injury to this tract results in involuntary movements such as in paralysis agitans. (3) The *antero-lateral descending tract* of Löwenthal lies at the anterior margin of the cord. It is continuous with the posterior longitudinal bundle, and ends directly round the cells of the anterior horn. The *bundle of Helweg* or *olivo-spinal tract* passes from the inferior olive to the cervical region of the cord. Its function is not yet known. (4) Other smaller descending tracts connect various parts of the brain with the spinal cord. (5) Other fibres connect different levels of the spinal cord together.

Functions.—The functions of the spinal cord fall into two categories—first, that of the gray matter, which consists of the conversion of afferent into efferent impulses, i.e. *involuntary or reflex action*; and second, that of the white matter, which is *conduction*. For each segment of the vertebral column there is a corresponding segment of the spinal cord with two pairs of nerves connected with it, one anterior or motor, and the other posterior or sensory, each of which is in relation at the periphery with definite groups of muscles and cutaneous areas, there being a true segmentation of the body surface as well as of the muscles corresponding to each spinal segment. The spinal cord thus represents a series of central organs which were originally independent, but have now fused, and their functions have mingled. What remains of their primary independence is confined to the simplest reflex acts, which are to be regarded as the elementary nervous process which underlies the most complex activities of the spinal system. The long conduction nerve tracts passing from the cord to the brain constitute so many intercentral reflex arcs, by means of which the spinal mechanisms of the higher vertebrates are brought into direct functional communication with the brain mechanisms. It is through these long conducting paths that, with the development of definitely conscious sensations and voluntary movements, the spinal cord ceases to be a collection of autonomous centres and becomes the instrument of the brain. At the same time it may also exhibit activity independently of the higher centres, and different reflex centres may be localised at different levels, as shown by the fact that the integrity of the cord is not essential for reflex action, an isolated segment being sufficient. If the gray matter of the cord be destroyed, all reflex action ceases.

Nearly all spinal acts present the character of reactions induced by external influences, and are adapted to adjust the organism temporarily to its environment. They have been divided into two classes—first, those where the sensory stimulus is injurious to the organism and the reflex aim is to remove the stimulus, or to remove the point of the body stimulated, i.e. they are *defensive*; and second, those where the stimulus is favourable to the normal development of useful functions such as walking. Reflex actions, however, although they depend on afferent excitations from sensory end-organs and elsewhere, as opposed to voluntary actions where the stimulus comes from the brain, depend also on influences from other portions of the nervous system which may moderate or depress their activity or may augment it, the former being termed *inhibition*, the latter *facilitation*. In man the brain normally exerts a marked inhibitory in-

fluence upon the spinal reflexes, and thus disease of the brain—e.g. apoplexy—results in an exaggeration of these reflexes by removing this inhibition. Disease of the spinal cord, if the lesion be transverse, produces loss of sensation and paralysis below the injury with loss of sphincter control, while circumscribed lesions may be localised by a study of the motor and sensory disturbances which they produce.

LITERATURE.—Alex. Bruce, *Topographical Atlas of the Spinal Cord* (1901); Villiger, *Brain and Spinal Cord* (1912; new ed. 1926, translated by Pierson); Sherrington, *Integrative Action of the Nervous System* (1906); Luciani, *Human Physiology* (vol. iii, 1916).

CURVATURE OF THE SPINE.—There are two main forms of this disease, which are due to different causes—viz. Angular Curvature or Pott's Curvature, and Lateral Curvature.

Angular curvature, which was first described by the famous surgeon Percival Pott (1713–88), and is hence often named after him, is due to disease of the bodies of the vertebrae and of the intervertebral discs. It usually takes the form of a tubercular disease of the bones, which become carious and destroyed, and of ulceration of the discs between them. The result is that the bodies of the diseased vertebrae give way and the column becomes bent forward on itself, while the spinous processes form a backward projection opposite the diseased part—hence the name angular curvature. This projection is most marked when the disease is in the dorsal region of the spine. If the disease is arrested the bones become firmly united, and the curve of the spine becomes permanent. In unfavourable cases abscesses may develop in the neighbourhood, and either press on the spinal cord or on the spinal nerves, or burrow in various directions, notably in the lumbar region (psoas abscess). The disease is often set up by an injury which may be severe, such as the falling of a heavy weight on the back, or in children may be some trifling twist or fall, such as may occur during rough play or from falling out of bed or from a chair. It most often occurs in delicate children with a tubercular family history, but it is by no means unknown in those whose family and personal history is quite unexceptionable, and it may even affect adults. Its early symptoms are often obscure, and consequently may be overlooked at a time when treatment is of most avail. There is at first little or no deformity, but there may be pain on percussing the spine of the affected vertebra. There is also usually an avoidance of all movements which may lead to jarring of the spinal column or to painful pressure on the nerves. If the vertebrae of the neck are affected the child often supports its chin by the hands, and does not willingly turn its head round. Disease of the dorsal or lumbar vertebrae is generally indicated by cautious movements, especially in coming down a stair, the avoidance of stooping or bending, or sudden twisting of the body. A child will thus get down on its knees to pick anything off the floor rather than stoop.

The treatment requires to be both local and constitutional. It is always protracted for months or even years. The general treatment is mainly that required for stercuous constitutions, such as codliver-oil, iron, hypophosphite of lime, &c. The local treatment involves absolute rest in the recumbent position in the early stage, with counter irritation over the spine in the neighbourhood of the disease. In later stages mechanical supports are also required to keep the vertebrae from pressing on each other. The kind of support needed varies with the region affected; one very valuable form for hospital practice consists in the application, during the suspension of the patient, of a

plaster of Paris jacket to the body. The more carefully rest in the recumbent position and mechanical support are carried out, the less, as a rule, will be the resulting deformity, the greater the prospect of avoiding complications and of obtaining permanent cure.

Lateral curvature consists in a twisting of the bodies of the vertebrae on each other round their vertical axis. It is sometimes a result of rickets, but is far more frequently developed in growing girls of feeble muscular development and general health, between the ages of ten and sixteen. It is produced in the first instance by the continued maintenance of asymmetrical positions of the body, such as by sitting sideways or cross-legged before a school-desk, or by carrying a weight on one arm. This curvature is usually to the right in the dorsal region with a corresponding twist to the left in the lumbar region. One shoulder, usually the right, becomes elevated, and the scapula projects, while the right side of the chest becomes rounded and the left side flattened. The lungs and liver become compressed and subject to disease, and the gait becomes awkward. This disease is due in the first instance to rotation of the bodies of the vertebrae on each other as the result of the irregular pressure. Later the ligaments and articular processes of the vertebrae undergo permanent changes, while the muscles may atrophy or undergo fatty degeneration. The ribs also become distorted, those at the side of the convexity of the curve bending at the angles, those at the other side becoming flattened.

The treatment of this form differs entirely from that of angular curvature. As the disease is due to the continuance of asymmetrical positions of the body, combined with muscular and general debility, general tonics, fresh air, and gymnastic exercise specially directed to the strengthening of the weakened muscles must be adopted. In the later stages, when the deformity has become more confirmed, mechanical supports may be required as an adjuvant to the above.

SPINA BIFIDA is a congenital malformation occurring perhaps more frequently than any other except hare-lip, and arising like it from arrest of development. It may be regarded as a congenital hernia of the membranes of the spinal cord through a fissure in the wall of the bony canal. A tumour is thus formed, which is usually of a roundish shape varying in size from that of an egg to that of an adult head, lying in the middle line of the back, fluctuating, and adhering to the adjacent vertebrae either directly or by a pedicle. The usual termination of the disease is death. As the size of the tumour increases, fatal convulsions ensue; or the skin investing the tumour may ulcerate and the contents escape, in which case palsy or convulsion produces death. Occasional cases are, however, recorded in which patients with this affection have survived till middle life. Surgical treatment has, until quite recently, been unsatisfactory; but with improved modern methods successful results have in many cases been obtained. Moderate support by means of a hollow truss, or a well-padded concave shield, may tend to keep the disease stationary; and any interference beyond this is, in the great majority of cases, unadvisable. For other diseases connected with the spine, see MENINGITIS, MYELITIS, LOCOMOTOR ATAXIA, &c.

Spinazzola, a city of Southern Italy, 30 miles SW. of Bari. It was the birthplace of Pope Innocent XII. Pop. 11,000.

Spindle-tree (*Euonymus*), a genus of plants of the Celastraceae, a family of small trees or shrubs. The genus *Euonymus* has a lobed capsule and seeds surrounded by an aril, which in some of the species is remarkable for its brilliancy of colour.

The Common Spindle-tree (*E. europæus*), a native of Britain, chiefly of the southern parts, and of great part of Europe, is very ornamental when in fruit, and its aril is of a fine orange colour. It is a shrub rather than a tree. The wood is hard and fine-grained. It is used for the finer articles of turnery and for skewers. It was formerly used for making spindles, whence the name of the shrub. In Germany the shoots are bored for stems of tobacco-pipes. Charcoal made of it is much valued for crayons.

Spinel is a mineral composed chiefly of magnesia and alumina, and crystallising in octahedra. There are several varieties, which differ in chemical composition owing to isomorphous substitution, sometimes of the protoxides, but usually of the sesquioxides. *Spinel-ruby*, the typical spinel, is clear pink-red, and contains little or no iron: *Pleomaste* (*Ceylonite*), or *Iron-magnesia Spinel*, is dark green to black, containing iron; *Picotite*, or *Chrome Spinel*, is black, containing chromium oxide; *Gahnite*, or *Zinc Spinel*, is green to brown, containing zinc; *Hercynite*, or *Iron Spinel*, is black, and occurs massive, in this variety ferrous oxide replacing magnesia. Ruby spinel occurs as crystals imbedded in granular limestone, also with calcite in serpentine and in various crystalline schists, as also in the alluvial sands, &c. derived from the disintegration of these rocks. Pleomaste is an occasional constituent of eruptive rocks, and also of certain rocks which have undergone alterations from contact with eruptive masses. Picotite has been met with in basalt, but is more commonly seen in peridotite. Gahnite is of sparing occurrence in certain crystalline schists, while Hercynite is occasionally found in such rocks as granulite. The finer varieties of spinel are prized as gems—the red coloured ones being commonly called rubies. See RUBY.

Spinello Aretino, an Italian painter, was born at Arezzo about 1330, his father being a Ghibelline exile from Florence. The painter spent nearly all his life between his birthplace and his father's city, and died at Arezzo about 1410. His principal frescoes were done for the sacristy of the church of St Miniatus near Florence, for the *campo santo* (cemetery) of Pisa, and for the municipal buildings of Siena (a series illustrating the Italian wars of Frederick Barbarossa), with several others in and near Arezzo. Spinello enjoyed a great reputation in his own day, being compared, and by some preferred, to Giotto, whose style his own in some respects resembles. Unfortunately his frescoes have mostly disappeared; and his panel and enamel pictures, of which there are several in the galleries of Europe, do not equal his frescoes in excellence.

Spines. See THORNS.

Spinet. See HARPSICORD.

Spinfex, a name given to grasses of two distinct genera. (1) The botanical genus *Spinfex*, in Ceylon, India, Japan, and Australia, has its spikelets massed in spiny heads, which when ripe break off and blow about over the sands. (2) In Australia the name is more commonly given to the genus *Triodia* or Porcupine Grass (*T. pungens*, *T. irritans*, *T. Mitchellii*, *T. Cunninghamii*), very coarse, hard, and spiny grasses, which grow in tussocks, and in some interior parts of Australia covers hundreds of square miles at a stretch. These grasses cannot be eaten by any animal, and as the clumps are three or four feet high they make travelling very laborious and painful.

Spinning is the art of twisting fibrous substances into rounded strands of yarn fitted for weaving, or for thread or rope making. To form such strands two operations are essential—(1) the drawing out of uniform quantities of fibre in a

continuous manner, and (2) twisting the material so drawn out to give it coherency and strain-resisting power. The earliest and for ages the only spinning apparatus was the spindle with the distaff. On the staff the prepared (carded or combed) material, wool or flax, was loosely wound, and it was held in the left hand or

Fig. 1.—Spindle and Whorl.

stuck in the belt of the spinner. The spindle (fig. 1) was a smaller tapering rod, the rotation of which gave the twist, and around which the thread was wound as it was twisted. The twist was given by causing the spindle to rotate against the person, and allowing it to fall towards the ground whilst spinning around. To give the spindle increased momentum it was weighted with a whorl (fig. 1) of stone or metal, but as the weight of the yarn on it increased this make-weight was removed. A graphic description of this method of spinning is given by a Scottish rhymester of the 18th century.

To save their plaiding coats some had
Upo' the hame a bonnet braid
On an auld weel or kauring skin
To rub and gar the spindle rin
Down to the ground w' twirling speed
An' twine upo' the floor the thread

Simple as it is, the spindle has continued in use from prehistoric times to the present day: even in some outlying regions of the Scottish Highlands and Islands, Sir Arthur Mitchell reported that up to the date of his 'Rhind Lectures,' *The Past in the Present* (1880), yarn was still being made with it; and in India some of the exceedingly delicate yarn for Dacca muslins is made on the spindle. The first improvement on this simple apparatus consisted in fixing the spindle in bearings and causing it to rotate by a cord passed over a wheel. Next came the fitting on the spindle of a separate bobbin to receive the spun yarn, and this in effect constitutes the charka or spinning-wheel of the East, which has there been used from time immemorial, and also the 'muckle wheel,' the use of which continued in Scotland till recent times. This simple wheel was known in Europe as early as the 14th century, but the greatly improved small or Saxon wheel (fig. 2), with a treadle motion giving continuous rotation to the spindle and allowing the spinner to sit with both

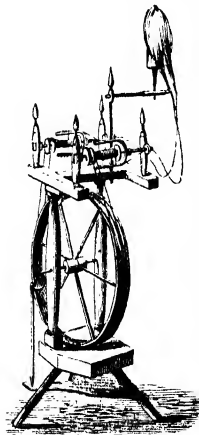

Fig. 2.—Two-spindle Distaff.

hands free, was not known till much later times. In the spinning-wheel in its improved form a bobbin or pira with a separate motion was placed on the spindle (fig. 3), which had two bent arms, the flyer or flight, for winding the yarn on the bobbin. The bobbin and flyer revolved at different rates—the revolutions of the spindle giving the twists and the difference of rotation causing the winding on. In such wheels it was possible to have two spindles and piras a little apart (the two-spindle wheel, fig. 2), with distaff-stand between them, and on

these the spinster produced thread with each hand. The introduction of mechanical spinning towards the end of the 18th century largely destroyed this domestic craft, though in the northern and western Highlands of Scotland, and also in the 'home-spun' industry of Ireland, yarn still continues to be made by the cottagers on the hand-wheel.

Invention of Spinning Machinery.—The series of inventions which overthrew hand-spinning may be said to have begun by Lewis Paul in 1738, when he patented the important principle of drawing out and attenuating a sliver or loose coil of fibre by passing it between successive pairs of rollers revolving at increasing rates of velocity. This principle of drawing out fibres by accelerated motion was developed in the spinning-frame or throstle invented by Arkwright in 1767, and it forms a fundamental feature of all modern spinning machinery. About 1764 James Hargreaves at Standhill, near Blackburn, invented his spinning-jenny (fig. 4), an apparatus by which eight threads could be spun at once, and this was soon improved upon until eighty could be produced as easily. In this apparatus a number of large reels filled with thickish coils of fibre called rovings were set on upright fixed spindles, and the ends of such rovings were passed between two small movable bars of wood placed horizontally and under the control of the spinner, who could thus make them press more or less on the rovings, and consequently increase or decrease the draw upon them from the spinning-spindles, which were set in a row in the carriage or movable frame. These spinning-spindles gave the twist to the rovings when they were fully drawn out, and thereafter wound on themselves the twisted yarn by being moved in the frame towards the bobbins of roving whilst they continued to rotate. The principle of the jenny was important and, developed in the spinning-mule of Crompton in 1779, it is the basis of the second of the two great methods of machine-spinning now in use. Crompton's inventions, along with the improvements of Paul and Arkwright, constitute the basis of all modern 'frame' spinning, as Hargreaves's 'jenny' constitutes the basis of 'self-actor' spinning, whether adopted in the construction of cotton, woollen, or the class of worsted yarns prepared and spun on the French system.

Preparatory Treatment of Textile Fibres.—All textile materials require to undergo a measure of mechanical separation, blending, and re-anagulation before a level yarn is producible by the insertion of twist or twine for converting a thick, loosely formed 'sliver' or 'roving' into a weavable thread. The objects of this preliminary treatment are: (1) The cleansing and freeing of the natural product—cotton, flax, jute, wool, 'waste' silk, &c.—of foreign matter; (2) the disentanglement and opening of the 'staple,' literally separating filament from filament; (3) for self-actor spinning—the re-grouping and re-combination of the fibres into a thin, gossamer-like web; (4) the division of this web into slivers or shubbings of corresponding weight and thickness throughout their length, and frictionally imparting to each a uniform rounded consistency; and (5) the attenuation of the slivers into yarns of the requisite diameter, simultaneously with the addition of twist. For frame-spinning, either prior to or following carding (2), varying with the staple selected and the structure

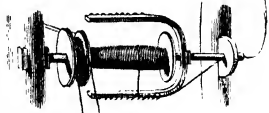

Fig. 3.—Spindle, Bobbin, and Flyer of fig. 2 on larger scale.

of yarn intended, the slubbings are repeatedly drafted and doubled, attaining in stages of work, and not in one operation, a roving in which the fibrous units are assorted and grouped in absolute line order.

In illustration, take the instance of cotton. Here the opening and partial cleaning of the matted

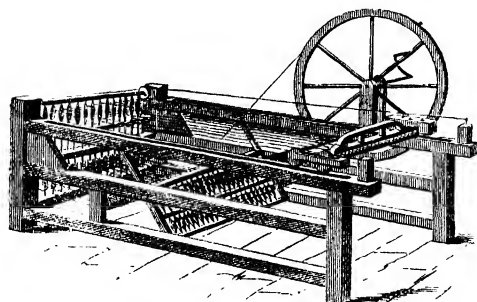

Fig. 4.—Hargreaves's Jenny.

fibres are secured by passing the material through two machines called respectively the opener and the scutcher. In these machines are cylinders revolving at a high rate of speed, with their surfaces studded with stout teeth which seize separate flocks of the fibre, and carrying it round, form a broad uniform teased mass which is called a lap. In the first of these machines it is also submitted to a

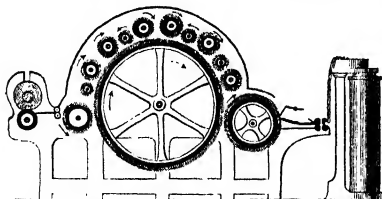

Fig. 5.—Sections of Carding-engine.

strong current of air which blows dust and dirt out of the cotton. From the scutcher a well opened and spread lap of the fibre is delivered to the carding engine (fig. 5), in which a series of cylinders of various sizes, and rotating at different velocities, further open and tease the fibre. The cylinders are covered with teeth of fine wire (fig. 6) bent at about half their length, of which there may be from six

Fig. 6.
a, card wire; b, card setting.

to seven millions in a single machine. According to the direction in which the cylinders rotate, and the rate of their revolution, the wire points may meet each other, or the points and flat sides of the wires may meet and pass; and in this way certain cylinders lift the fibre from their neighbours and pass it on to others, so that the fibre is gradually teased, brushed, and spread out in a uniform

manner. From the carding-engine the fibre is delivered in a broad lap; but by passing it through a ring or tube it is compressed into a soft rounded coil or sliver. This sliver is taken to the drawing-frame, which consists of, say, four successive pairs of rollers, each pair in succession going at a greatly accelerated rate, so that the last pair may be going

six times quicker than the front pair. In this way a sliver is drawn out six times its original length, and six slivers fed in come out the thickness of one. This drawing out ultimately brings the slivers to a very uniform thickness, and places the fibres in a parallel order. It may be repeated many times, and thereby the fibres which lay together in the original strand may be drawn out to a great length. Thus, passing a sliver of one yard three times through the drawing-frame elongates it to $6 \times 6 \times 6 = 216$ yards, or four times passed through it is stretched out to 1296 yards. For fine yarns this drawing out frequently repeated may represent an elongation many thousand-fold. In the slubbing-frame comes the beginning of the spinning process, the sliver being here further drawn out and twisted sufficiently to enable it to be wound on a bobbin. The intermediate frame draws out two slubbings to the thickness of one, again slightly twists it, and winds it on a bobbin. In the roving-frame the slubbing is drawn out further, slightly twisted, and wound on a bobbin.

Frame-spinning Machines.—Frame-spinning is done on the 'flyer,' the 'cup,' or the 'ring' principle. In the flyer, the roving bobbins, arranged in the upper and rear portion of the framework of the machine, deliver the rovings to a pair of back rollers, from which they are continuously transferred to a pair of front rollers. The differentiation in the surface velocities of these two sets of drafting rollers determines the extent to which the rovings are stretched in length and reduced in circumference. Leaving the front pair, the rovings are conveyed round the 'wings' of the flyer—revolving on the spindle positively driven—to the bobbin running on the spindle, which is made to rotate by the 'drag' of the flyer. As the bobbin increases in diameter it gains in weight, and its movement is thereby retarded. This maintains a constant length of yarn being wound up with the ever-changing dimensions, during spinning, of the yarn spool.

In the 'cup' and 'ring' frames the methods of roving delivery and of drafting are identical with the methods common in the 'flyer' practice. The spool now revolves with the mechanically driven spindle. Twist is developed by the yarn gyrating on the rim of the cup, from which it is distributed, layer by layer, on to the rapidly rotating bobbin. On the ring system, a small metal 'traveller' is made to turn on the edge of a circular plate by the yarn as it passes from the 'nip' of the rollers to the spool, the difference between the surface speed of the latter and that at which the yarn escapes from the rollers fixing the 'turns' per inch, or the amount of twist, inserted into the spun yarn.

Spinning on the Self-actor.—Self-actor spinning is carried out on two principles—first, by *spindle*, and, second, by *roller drafting*. In the former the slivers are taken from 'condenser' bobbins, horizontally placed in the fixed frame of the machine, and passed between a pair of pressure and feed rollers to the spindles. The latter are mounted on the carriage which travels away from and towards the frame and 'headstock'—control mechanism—successively. The process of spinning is intermittently performed. Thus the rollers com-

mence to deliver the slivers concurrently with the beginning of the outward traverse of the carriage. On a fraction of this being completed, during which the spindles are actively rotated, the motion of the rollers is suspended, the carriage, meanwhile, continuing to draw out or draft the threads, and the spindles to generate twist. The insertion of twine is further proceeded with for a brief period after the carriage has reached the end of its movement. Up to this stage all the threads have been held by the 'faller' wire on a line with the top of the spindles, preventing that rotation from winding up the yarn, and effecting twisting only. This done, the 'fallers' bring the yarn into such a relation with the spindles that - following their momentary reversal for removing any excessive degree of twine in the length of yarn approaching the spindles—they are again put into correct action for winding the yarn on to the 'cops' as the carriage returns to the headstock and bobbin frame. *Roller drafting* enables the rovings to be given out at a uniform rate from the start to end of the traverse of the carriage, with the development of a regular degree of twist. Final twisting, on the stopping of the carriage, and winding of the yarn on to the spools or 'cops,' are features common in the two practices. The application of spindle-drafting is in the manufacture of woollen and certain varieties of cotton yarn, while that of roller-drafting is in the spinning of yarns having a smooth and level formation.

Yarn Counts and Diameters.—Cotton yarns are spun in counts (hanks per lb.) ranging from 5's to 300's (= 5 to 300 × 840—yards in a hank—per lb.); linen yarns in counts (leas per lb.) from 3's to 900's (= 3 to 900 × 300—yards in a lea—per lb.); worsted yarns from 5's to 120's (= 5 to 120 × 560—yards in a hank—per lb.); and woollen yarns from 1 to 48 skeins or from 1 to 48 yards per dramm. The diameter of 300's cotton is $\frac{1}{16}$ -inch, 120's worsted $\frac{3}{16}$ -inch, and of 48 skeins woollen $\frac{3}{16}$ -inch. Previous to the invention of the self-acting few spinners could make yarn of 200 hanks to the pound. At the same time the natives of India were weaving yarn of numbers ranging between 300 and 400. Lancashire spinners have produced yarn of 700 hanks per lb. for fine muslin goods, and, for testing machinery running and efficiency, yarn of a much higher count has been spun.

Spinola, AMBROSIO, MARQUIS OF, one of the greatest captains of his time, was born at Genoa in 1571. With his younger brother Frederick, already a soldier of fortune under Philip III. of Spain, he raised in 1602 a force of 9000 men, whom he maintained, like the old *condottieri*, at his own expense. In the same year he entered the Netherlands, serving at first under Mendoza. His first exploit was the reduction of Ostend, which the Archduke Albert had been besieging for more than two years. This spread his reputation over Europe, and led to his being placed at the head of the whole Spanish and Italian troops in the Netherlands. Now began a long struggle with Prince Maurice of Nassau, in which neither could gain any decided advantage over the other. The destruction of the Spanish fleet near Gibraltar induced the court of Madrid to conclude in 1609 an armistice for twelve years. At its termination the war began anew, and Spinola found himself once more pitched against his great opponent, who, however, died at the Hague in April 1625 without succeeding in raising the siege of Breda. The town opened its gates in the May of 1625, after having sustained a siege of ten months. This was Spinola's last achievement, his health now obliging him to resign the command. He had spent his whole fortune in the maintenance of his troops, but his pecuniary claims were shamefully neglected by the Spanish government, and his acute vexation at

this hastened his death, which took place in Piedmont, 25th September 1630.

Spinoza, BENEDICT (*Benedictus* being a translation of the Hebrew *Baruch*), one of the greatest philosophers of modern times, was born at Amsterdam on the 24th of November 1632. His parents were rich Spanish or Portuguese Jews, whose name (also spelt D'Espinosa and Despinosa) seems to have been derived from a village called Espinosa in León. They had their son diligently instructed in the Bible and its commentaries, and the Talmud; but after having mastered both, and imbibed the philosophical spirit of such commentators as Alen Ezra, he was allowed the more readily that his sickly constitution unfitted him for a commercial career—to devote himself entirely to a life of study. Physical sciences and the writings of Descartes, to which he turned first of all, very soon drew him away from the rigid belief and practices of the synagogue; and Saul Levi Morteira, his Talmudical teacher, who had built the fondest hopes upon the genius of his pupil, was the first to threaten him with the direst punishment if he did not retract the rank heresies that he began openly to utter. Spinoza, after a time, entirely withdrew from the community of his brethren, who formally excommunicated him (1656). A fanatic even attempted to frighten him by an either real or feigned attack upon him as he left the synagogue one night. At that period the young truth-seeker made the acquaintance of the young and beautiful daughter of Van den Ende, his master in Greek and Latin, and fell passionately in love with her, but was rejected. From that time forth Philosophy became the sole aim and object of his life. In accordance with the teachings of the sages of the Mishna, Spinoza had, apart from his studies, made himself master of a mechanical craft; he had learned the art of polishing lenses, and this now became the means of his subsistence.

When twenty-eight years old he left Amsterdam, and went to Rijnsburg, near Leyden, then the headquarters of a sect of the Remonstrants or Arminians, known as Collegiants, with one of whom he lived; and there he wrote the *Abridgment of the Meditations of Descartes*, with an Appendix—the latter being the first draft, so to say, of his *Ethics*. The year following he removed to Voorburg, a suburb of the Hague, and shortly afterwards, yielding to the solicitations of his, by this time, numerous friends, he removed to the Hague itself. The Elector Palatine, Charles Louis, next offered him a vacant chair at the university of Heidelberg, with full 'liberty of teaching,' provided he would not say aught to prejudice the established religion—i.e. Christianity; but Spinoza declined the lucrative and honourable professorship. His small pittance was enough to satisfy his wants. Similarly he refused generous offers made to him by wealthy friends, like Simon de Vries, who intended to bestow a large sum of money upon him; all he could be prevailed upon to accept was a small annuity of a few hundred florins. An offer of a pension, on the condition of his dedicating a work to Louis XIV., he rejected with scorn. His domestic accounts, found after his death, show that he preferred to live on a few pence a day rather than be indebted to another's bounty. He died, forty-four years old, on the 21st of February 1677. Throughout his life of study, of abstinence, of bodily and mental suffering—for his constitution was no less undermined by consumption and overwork than his sensitive mind was wrought upon by the violent severance of all natural ties of affection, to say nothing of the misery of occasional want and of perpetual persecution—no complaint ever passed his lips. Simplicity and heroic forbearance, coupled with an antique stoicism and a child-

like, warm, sympathising heart, were the outstanding features of him who was nicknamed epicurean and atheist by his contemporaries.

Spinoza's philosophical system developed itself on the basis of Descartes (q.v.), who, dissatisfied with both the *dogma* and the scepticism around him, cleared the ground by first doubting everything, and then laying a new foundation in *Cogito, ergo sum*. Spinoza, however, took his 'I think, therefore I am' merely as a starting-point to establish not (as with Descartes) an unreconciled dualism of spirit and matter, but a pure Monism, of which the sole foundation is Substance—'that which is in itself and is conceived through itself,' with an infinite number of Attributes, of which thought and extension, or spirit and matter, are alone dealt with. Spinoza's one Substance, *causa sui*, he expressly calls God; yet this term is not to be understood in the ordinary sense, for Spinoza's God neither thinks nor creates. There is no real difference, he holds, between mind, as represented by God, and matter, as represented by Nature: they are One, and, according to the light under which they are viewed, may be called either God or Nature. The visible world is not distinct from him. It is only his visible manifestation, flowing out of him, who is the first fountain of life and essence, as a finite from the infinite, variety from unity—a unity, moreover, in which all varieties merge again. Extension and thought, which with Descartes had been two Substances, with Spinoza become Attributes—that which the mind perceives as constituting Substance. Extension is visible Thought; Thought is invisible Extension. And this explains the relation between body and mind, and the perfect harmony between them. The mind is the idea of the body—i.e. the same thing considered under the attribute of thought. Substance as thought falls into an infinite number of Ideas, and as extension into an infinite number of Bodies. These Spinoza calls Modes. The *modus* or *accidens* is only the varying form of Substance. Like the curling waves of the ocean, the modes have no independent existence; they are simply the ever-varying shapes of the Substance. Substance thus is the only really existing, all-embracing essence, to which belongs every thing perceptible to our senses, and every thing not perceptible. Thus, every thought, wish, or feeling is a Mode of God's Attribute of thought; every thing visible is a Mode of God's Attribute of extension. God is the 'immanent idea,' the One and All, the *natura naturans*; World, *natura naturata*, is one complex whole and one peculiar aspect of God's infinite Attribute of extension. The variety we behold in things is a mere product of our faulty conceptions, particularly of what Spinoza terms our 'imagination,' which perceives unity as a complex of multiplicity. The connection of things is the same as the connection of ideas; we attain the truth only when, looking away from the multiplicity of ideas and of things, we behold God *sub specie æternitatis*.

His system is mainly contained in his *Ethica*, which is not a treatise of Ethics, but a complete philosophy. The *Ethica* he deduces in a mathematical form, after the method of Euclid, but with a stringency much more apparent than real. Chief doctrines are: The absence of free-will in man—himself only a *Modus* dependent on causes without, and not within him. Will and Liberty belong only to God, who is not limited by any other Substance. Good and Evil are relative notions, and sin is a mere negative; for nothing can be done against God's will, and there is no idea of Evil in him. Utility alone, in its highest sense, must determine the good and the evil in our mind. Good, or useful, is that which leads us to greater reality, which

preserves and exalts our existence. Our real existence is knowledge. Highest knowledge is the knowledge of God. From this arises the highest delight of the spirit. Happiness is not the reward of virtue, but virtue itself; and this is to be attained by a diligent following in God's ways. Sin, evil, negation, &c. are merely things that retard and obstruct this supreme happiness. Spinoza's Pantheism was long regarded as 'the most iniquitous and blasphemous human invention,' and had few followers even in Holland. But in the 18th century it attracted the admiration of men such as Lessing, Herder, and Goethe, and became with Fichte, Schelling, and Hegel the acknowledged basis of much of modern German philosophy; even Schleiermacher spoke of Spinoza as 'pious, virtuous, God-intoxicated.'

Spinoza's principal works are *Renati Descartes Principia Philosophiæ More Geometrico Demonstrata* (1663); *Tractatus Theologico-politicus* (1670); *Ethica Ordine Geometrico Demonstrata*; *Tractatus Politicus*, *Tractatus de Intellectus Emendatione*; letters; and a Hebrew grammar; and, not published till 1862, *Tractatus de Deo et Homine*. The *Tractatus Theologico-politicus* contains an acute and rationalistic view of revelation. In his politics he has many points common with Hobbes. Spinoza's life was made by Auerbach the subject of a romance. There are editions of the works by Paulus (1803), Bröder (1846), and Van Vloten and Land (1883; 3d ed. 1914); translations by Elwos (1884), Hale White (1883; revised by Stirling, 1910), and others; and English books on him by Sir F. Pollock (1880), Martineau (1882), Caird (1888), Joachim (1903), Duff (1903), and Pleton (1907); works in German by Sigwart (1839), Thomas (1840), Camerer (1877), Baltzer (1888), Freudenthal (1899), Meissner (1909); in French by Sautes (1842), and Lévêque (1923); in Danish by Hoffding (trans. 1925). Professor A. Wolf has edited a contemporary Life (1927), and his *Correspondence of Spinoza* is the beginning of a five-volume translation of the complete works.

Sintharoscope, a simple little instrument consisting of a screen of sulphide of zinc with a minute fragment of radium salt held on the point of a needle above it, together with a lens through which to look at the glow resulting from the bombardment of the screen by the radio active substance, and to analyse it into its constituent flashes or scintillations. See ATOM.

Spiræa, a genus of plants of the family Rosaceæ, and of the sub-family Spiræoideæ (in which the

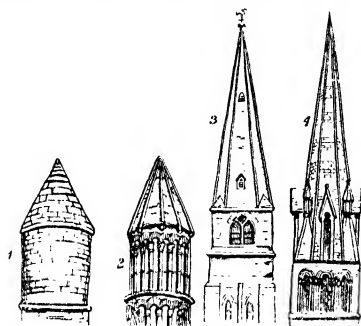

Spiræa Aruncus, or Goat's Beard.

fruit consists of five or fewer capsular carpels). *Spiræa* has one or more follicular, many-seeded

carpels. The numerous species are herbaceous plants and low deciduous shrubs; of the herbaceous species two are natives of Britain, Dropwort (*S. Filipendula*) and Meadow Sweet or Queen of the Meadow (*S. Ulmaria*), both with interruptedly pinnate leaves and flowers in cymes. Dropwort is a native of dry upland pastures; it is tonic and fragrant; and its tubers, which are somewhat nutritious, have been ground and made into bread. Meadow Sweet is well known for the powerful fragrance of its flowers. A fragrant distilled water is prepared from them. A North American species (*S. tomentosa*), called Hardhack in the United States, is there used as a tonic and astringent. Many of the shrubby species are frequently planted for ornament.

Spiral Vessels. See STEM.

Spire, a very acute pyramidal roof in common use over the towers of churches. The history of spires is somewhat obscure, but there is no doubt that the earliest examples of anything of the kind are the pyramidal roofs of the turrets of Norman date. Those of St Peter's, Oxford (fig. 1), and Rochester Cathedral (fig. 2) are good specimens of

1, Turret, St Peter's Church, Oxford; 2, Turret, Rochester Cathedral; 3, St Mary's Church, Cheltenham; 4, Bayeux Cathedral, Normandy.

circular and octagonal pointed roofs, or spires in an embryonic condition. Spires of this early period are much less acute than those of later date. The Early English style has spires of sharply pointed form over the larger towers. They are generally octagonal and what are termed broach spires—i.e. the slopes spring from the cornice of the tower without any parapet, and at the point where the square changes to the octagon there is a small set-off or separate roof (fig. 3). Sometimes the angles at top of towers were occupied with pinnacles or sloping masses of masonry, as at Bayeux Cathedral, Normandy (fig. 4).

In the Decorated style the spires were more ornamented, having generally a parapet and pinnacles at the top of the tower, crockets on the angles, and enriched windows. The spires of the Perpendicular and Flamboyant styles are still more enriched, with flying buttresses at the angles, &c. They are sometimes perforated, and the sides of the spire filled entirely with tracery. Such spires are common in Germany, those of Strasbourg and Freiburg on the Rhine being very fine examples, as also that of St Stephen's, Vienna. As in the later styles generally, the character and beauty of the spire give place to dexterity in masonry, and many examples exist of traceried spires more wonderful than beautiful (see GOTHIC

ARCHITECTURE). Spires are most frequently constructed of stone, but they are also occasionally made of wood, and covered with lead, copper, slates, or shingles. These are chiefly to be found in localities where stone is scarce. Among famous spires may be mentioned those of Ulm (530 feet), Cologne (q.v., 515), Ronen (of cast-iron, 487½), St Nicholas, Hamburg (482), Strasburg (465), Chartres (q.v., 371), and Salisbury (q.v., 404), the highest in England, as St Mary's Cathedral, Edinburgh (275), is the highest in Scotland, and St Patrick's Cathedral, New York (328), in America. With these heights may be compared the Eiffel Tower (985 feet), the Washington obelisk (555), the Forth Bridge (361), and the domes of St Peter's at Rome (435) and St Paul's in London (404).

Spires. See SPEIER.

Spirifer, a genus of brachiopods. See the article CARBONIFEROUS SYSTEM.

Spirillum. See BACTERIA, GERM THEORY, CHOLERA, RELAPSING FEVER.

Spirit, a name of very general application to fluids, mostly of a lighter specific character than water, and obtained by distillation. Thus, the essential oil of turpentine is called Spirit of Turpentine; a looser usage extended the name to Spirit of Nitre (nitric acid) and Spirit of Salt (hydrochloric acid). But in a stricter sense the term spirit is understood to mean Alcohol (q.v.) in its potable condition.

Spirit, HOLY, or HOLY GHOST, or PARACLETE, the third Person in the Christian Trinity. The evolution of the doctrine has its roots in the Old Testament. The term 'Spirit' originally meant 'breath' or 'wind' both in Hebrew and Greek (*ruach* and *πνεῦμα*)—the invisible principle of life in man and the universe—so it came to denote the invisible Divine activity working in the world—or 'God in action.' In the Old Testament the development of the doctrine of the Spirit is parallel to the development of the conception of God. There is always an equation between the character of God and the character of the activity of the Spirit. In the earlier period, when Yahweh was conceived as the Lord of Hosts or the God of Battles, the Spirit endowed the heroes of Israel with courage and prowess in war. It fell upon Othniel (Judges, iii. 10) and Jephthah (xi. 29). The case of Samson is the best illustration of this stage of development. In Judges, xiv. 6, the Spirit endows him with strength to rend a lion; it enables him to smite 'thirty men of Ashkelon and take their spoil;' in xv. 13 it empowers him to rend the ropes with which the Philistines had bound him. Sometimes, too, the spirit which God sends is evil—e.g. 1 Sam. xviii. 10, 'an evil spirit from God came mightily upon Saul.' In the next period—the period of the great prophets—the Spirit was regarded as the source of Divine knowledge and inspiration. It was the action of the Spirit which enabled the prophets to know and reveal the will of Yahweh. From this time onward the conception of the Spirit became ethicised (Neh. ix. 20; Ps. cxliii. 10), and its function is mainly connected with the development of the spiritual life in the nation or the individual. Its activity is never, however, limited to the spiritual realm, because in the latest literature of canonical books, as well as in Apocryphal and Apocalyptic literature, we find that the Spirit is regarded (a) as the agent of God in the creation of the natural universe, and the power that actuates and energises it; (b) as the source of human genius, and the bestower of exceptional skill in art and handicraft (Exodus, xxxi. 3).

With the development of a pure monotheism and the abandonment of anthropomorphic conceptions, and the consequent sublimation of the idea of God,

more stress still came to be laid upon the action of the Spirit as the mediator between God and the world. Like the companion conceptions of the 'Wisdom of God' and 'the Word of God,' the Spirit was gradually personified and even hypostatized, though it cannot be said that it was actually differentiated from God in the Old Testament.

The New Testament carried the doctrine to a higher plane of development. The adjective 'Holy,' which only occurs twice in the Old Testament and four times in Apocryphal literature, becomes almost an inseparable epithet of the Spirit, being used between eighty and ninety times, thus marking the fact that the conception has become completely ethicized. It cannot be said, however, that the New Testament contains a uniform doctrine of the Holy Spirit. There are considerable divergences between the theological implications in the statements of John and Paul. In the epistles of Paul there is no clear distinction drawn between the Spirit of God and the Spirit of Christ; in fact, sometimes, as in 2 Cor. iii. 17 ('Now the Lord is the Spirit'), the two are identified. The absence of a doctrine of the Logos makes it necessary for Paul to ascribe to the Spirit the attributes and functions which the fourth gospel assigns to the Logos. Nor is the difference between the Johannine and the Synoptic conception less marked. In the Synoptic gospels the Spirit is active in the incarnation, the baptism, and the temptation of Jesus. According to the fourth gospel, the activity does not commence till after the crucifixion. In vii. 39 it is distinctly stated that 'the Spirit was not yet (given), because Jesus was not yet glorified.' The Spirit is represented as the Paraclete whom Jesus will send to comfort and encourage his followers. But in one particular the Johannine conception marks a great advance. The Spirit is always personal, as personal as God or Jesus himself. And though the personality of the Spirit is definitely assumed in the baptismal formula of Matt. xxviii. 19 and the benediction of 2 Cor. xiii. 14, yet the conception is nowhere so vivid and clear as it is in the fourth gospel. The function of the Holy Spirit or Paraclete in the fourth gospel is (a) to be the Spirit of truth, and guide men into the truth (xiv. 16, xvi. 13); (b) to bear witness to Christ (xv. 26); (c) to convict the world of sin, righteousness, and judgment (xvi. 8-10). Another function assigned to the Spirit by Paul is 'to make intercession for men' (Rom. viii. 26). The doctrine of the Holy Spirit did not become a subject of controversy in the early church, though it was necessarily involved in the Christological and Trinitarian debates in the 3d and 4th centuries. Montanism, however, attempted to give special prominence and emphasis to the doctrine of the Spirit, and in the conflict between Montanism and the Catholic Church the issue largely turned upon the interpretation of the action of the Spirit. 'The strength of the Montanists was,' as Gwatkin says, 'in their vivid belief that the Holy Spirit was a power that had not ceased to work spiritual wonders in the church.' They maintained that they were the prophets of a 'new dispensation'—the dispensation of the Spirit—which was to supersede the earlier Christian dispensation as that had superseded the Old Testament. But though Montanism emphasised an aspect of truth which, with the developing machinery of church organisation, was in danger of being forgotten, yet its exaggeration and excesses on the whole did more harm than good, and the reaction from Montanism involved the overshadowing of the doctrine of the Spirit altogether. There was only one controversy in which the doctrine of the Spirit became the centre of attack. In the 4th century the Macedonians, or Pneumatomachoi, while they were perfectly orthodox on Christology,

denied the consubstantial divinity of the Holy Spirit. The Macedonian movement, however, never assumed large dimensions. The battle in the 4th century ranged almost entirely around the person of Christ. The acceptance or rejection of the Nicene position on the one point almost always carried with it a similar attitude upon the other.

In later centuries the dispute about the 'Filioque' clause, as it is called, led to the final cleavage between the Eastern and Western Churches. The Nicene Creed describes the Holy Ghost as 'proceeding from the Father.' Gradually, however, the Western Church added to that formula, 'and the Son.' The additional clause made its first conciliar appearance in the acts of the third Council of Toledo (589). From Spain it spread into France, where it seems to have won general acceptance in the time of Charlemagne. The Greek Church at once began its protest. It regarded the new phrase as an unwarranted expansion of the statement in John, xv. 26. Successive popes became champions of the new clause, with the consequence that the tie between East and West, which had already been severely strained by other causes, snapped completely.

In recent times there has been a revival of interest in the doctrine. One of the most interesting signs of this revival is to be found in the publication of a volume of essays, entitled *The Spirit*, edited by Canon Streeter. These essays are an attempt to deal with the doctrine from the point of view of religious psychology and experience. The doctrine is regarded as representing the activity of God in human life, and as therefore affording a means of harmonising the immanent and transcendent sides in the Divine nature.

See older works by Heber, Hare, Hutchings, Smeaton, Candlish; modern by Streeter (ed.), Swete, Rees, Gunkel, Kahnis; also books on Biblical Theology—e.g. Old Testament: Schultz, Smead, Davidson; New Testament: B. Weiss, Holtzmann, Deyschlag, Feine.

Spiritualism (as it were, 'the doctrine of the spiritual'), sometimes also called Spiritism ('the doctrine of spirits'), is the name applied to a great and varied series of abnormal or preternormal phenomena purporting to be for the most part caused by spiritual beings, together with the belief thence arising of the intercommunication of the living and the so-called dead. The following is a definition given in the London *Spiritual Magazine*, for many years the best exponent of the subject in Great Britain: 'Spiritualism is a science based solely on facts; it is neither speculative nor fanciful. On facts and facts alone, open to the whole world through an extensive and probably unlimited system of mediumship, it builds up a substantial psychology on the ground of strictest logical induction. Its cardinal truth, imperishably established on the experiments and experiences of millions of sane men and women, of all countries and creeds, is that of a world of spirits, and the continuity of the existence of the individual spirit through the momentary eclipse of death; as it disappears on earth reappearing in that spiritual world, and becoming an inhabitant amid the ever-augmenting population of the spiritual universe.'

The movement known as 'modern spiritualism' is usually considered to have commenced in the year 1848, with certain mysterious noises and movements occurring in a house temporarily occupied by Mr Fox and family at Hydeville in the state of New York; and his two daughters, Margaret and Kate, aged twelve and nine years respectively, were the first individuals recognised as mediums, in whose presence the phenomena more particularly occurred. It must not be supposed that the phenomena them-

selves were at all new. Throughout all history there are records of similar occurrences. Such were the disturbances at the ancient palace of Woodstock in 1649; at Mr Mompesson's at Tedworth in 1661; at Epworth parsonage in 1716, in the family of Mr Wesley, the father of the founder of Methodism; the Cock Lane ghost in London investigated by Dr Johnson, Bishop Percy, and other gentlemen; the extraordinary occurrences in the house of Mr Jobson in Sunderland in 1839, which were investigated and published by Dr Clanny, F.R.S., and authenticated by sixteen witnesses, including five physicians and surgeons; and numerous less important cases recorded in the works of William Howitt, Robert Dale Owen, Dr Eugene Crowell, and many older writers. But none of these occurrences attracted much attention or led to any systematic investigation of the subject. What especially distinguishes the year 1848 is that it was the starting-point of a movement which has grown and spread continuously, till, in spite of ridicule, misrepresentation, and persecution, it has gained converts in every grade of society and in every civilised portion of the globe. Spiritualism is now to be found as frequently among the highest aristocracy as among the middle classes and the poor. It has its full proportion of believers in the foremost ranks of science, literature, and art, and in all the learned professions. In every European country, in America, and in Australia there are numerous periodicals which diffuse a knowledge of its phenomena, its teachings, and its philosophy; while it claims to have profoundly modified the teaching of some among our clergy as to the nature and purpose of the future life. These facts and characteristics broadly distinguish modern spiritualism as being very different from anything that has preceded it, and claim for it a respectful consideration.

When the knockings and movements of furniture were first heard and seen they were assumed to be due to some trick or other natural cause, and there was in every case and throughout the whole course of the movement a strong prejudice against any other explanation of them. When the Fox family could not detect this cause the neighbours were called in, but equally without result. It was soon observed that the more violent sounds or motions occurred in the presence or in the immediate vicinity of one or other of the little girls, and every precaution was taken against possible trick on their part. They were closely watched, were held hand and foot, were tied in bags or put to stand barefooted on pillows, but all in vain. The raps or loud knockings on doors or tables, on floor or ceiling, occurred just the same. But this was only a part of the phenomena. It was observed that the noises occurred at request, or as if in reply to observations. Then the alphabet was used, and questions were answered by raps at certain letters which, when written down, formed connected words and sentences. In this way the statement was elicited that the sounds were made by the spirit of a man who had been murdered in the house and buried in the cellar. After several explorations human bones with charcoal and lime were discovered there. Some confirmatory evidence as to this murder was obtained, and some of the previous dwellers in the house stated that they also had been disturbed by unaccountable noises. The excitement caused by these occurrences was so great that in order to satisfy the curiosity of visitors the Fox family were obliged to submit to public exhibitions and tests of the remarkable phenomena occurring in the presence of their children, and thus public mediumship began. But at the same time other mediums were discovered in different parts of the country, as if a special

development of this abnormal power were then occurring. A few of the more remarkable of these mediums may be here briefly referred to.

In 1845 an altogether illiterate youth, Andrew Jackson Davis, the son of a poor weaver and apprenticed to a shoemaker at Poughkeepsie, New York, began to exhibit remarkable powers as a trance speaker and a clairvoyant healer of diseases. During his trances he exhibited such extensive knowledge of subjects quite beyond his waking abilities or acquirements as to attract the attention of learned men, and under their auspices he delivered in New York 157 lectures which were afterwards published in a volume of 800 pages. These powers continued to be often exerted during a long life. One of his disciples was Thomas Lake Harris (q.v.), whose *Lyric of the Golden Age*, a poem of 384 pages, was dictated in ninety-four hours, and in the opinion of William Howitt deserves the praise that has been given it of possessing almost Miltonic grandeur. Just about the same time (1846-50) the Davenport brothers began to exhibit the remarkable physical phenomena that puzzled so many observers in every part of the world; and it was about the year 1846 that the celebrated medium Home, then thirteen years old, had his first vision of a boy friend, 300 miles away, who intimated to him that he had died three days before at a certain hour, which was afterwards found to be perfectly correct.

Nature and Range of the Phenomena.—In almost every case the medium is a person who in youth sees visions and hears voices which often communicate intelligence of distant and sometimes future events quite unknown to himself or family. Following such phenomena, and apparently to attract the attention of other persons, noises usually occur; sometimes voices are heard, and sometimes musical sounds. Then follow movements of material objects, either visibly or more often in the dark, or in such a way that the result only is seen. Rooms and even houses are sometimes shaken; bells sometimes ring violently without material cause; flowers, fruits, or other objects are brought from a distance into closed rooms, sometimes of particular kinds as desired at the moment by those present. Another curious phenomenon is the tying and untying of knots. Sometimes the medium is tied in such a manner that it is plainly impossible he could have so tied himself; sometimes when tied by other persons, and the knots and ends of the cords out of his reach, he is almost instantaneously released. Knots are sometimes tied on endless cords in a manner impossible by human agency, as in the experiments of Professor Zöllner.

A frequent phenomenon is the playing on musical instruments without human agency, as on an accordion held by the medium by one hand, and sometimes when held by spectators. Closed pianos are sometimes played on, while accordions or tambourines are, as it were, floated in the air and played upon at the same time.

Writing or drawing is often performed without human agency. Sometimes the writing occurs on papers held or thrown under the table, or when placed in locked drawers, or enclosed between slates tied or screwed together. Sometimes the writing thus obtained is in answer to questions which may be spoken or written, and either known or unknown to the medium. The drawings are of various kinds. Some are on slates with pencil or chalks, some on paper. Very effective drawings in crayons, water-colours, or oils are produced with extreme rapidity and under conditions which render normal human agency impossible. A Scottish medium was accustomed to produce small landscapes in oils on cards privately marked by the

witnesses and in total darkness, the result being seen with the paints still wet. These were usually effective and artistic works. In another case the space under a table was enclosed by a large shawl hanging to the ground. Marked cards were thrown underneath, and in from ten to fifteen seconds the drawings were complete. A number of these drawings were in the possession of the late Mr Benjamin Coleman, and were shown to the present writer. One in particular was on paper marked by Mr Coleman with two pin-holes by pins which were stuck through a small strip of paper which was kept as a proof of the identity of the paper so marked. The drawing that was made on this paper consisted of two birds holding a garland of flowers in their bills, and was so executed that the two pin-holes which had been made on the paper formed the eyes of the two birds, while their exact correspondence with the strip kept with the pins in it showed that the very paper Mr Coleman had so marked had been used. Lord Borthwick was present when these drawings were described, and confirmed Mr Coleman's account of them before the committee of the Dialectical Society in 1869.

One of the most striking of the physical phenomena is the levitation of the human body, which has occurred with many mediums, but has never been more thoroughly tested than with the late Mr Home. The extraordinary elongation of his body was also tested by many competent observers while in his presence, as in that of some of the mediums, heavy tables were often raised to a considerable height, or inclined at an angle of nearly 45°, without the numerous objects on the table, as books, glasses, lamps, &c., falling off.

A very marvellous phenomenon exhibited by Mr Home, and a very few other mediums, is the power of neutralising the action of fire, both in their own persons and in that of some of the spectators. Lord Lindsay (after 1880 Earl of Crawford) made the following statement before the Dialectical Society: 'I have frequently seen Home when in a trance go to the fire and take out large red-hot coals and carry them about in his hands, put them inside his shirt, &c. Eight times I have myself held a red-hot coal in my hands without injury, when it scorched my face on raising my hand. . . . A few weeks ago I was at a séance with eight others. Of these seven held a red-hot coal without pain, and the two others could not bear the approach of it.' Lord Adare, Mr Jencken, and several others saw Mr Home stir the fire with his hands and then put his face right among the burning coals, moving it about as though bathing it in water. Mrs S. C. Hall, the Earl of Crawford, and several others saw Mr Home place a large lump of burning coal on Mr S. C. Hall's head and draw up his white hair over the red coal. It remained there several minutes. After it was taken away it burned the fingers of some who attempted to touch it. A number of other persons of the highest character testified to similar occurrences with Mr Home.

Even more extraordinary, and still more remote from the normal powers of mankind, is the production of visible and tangible hands—which lift objects, and sometimes write, and then dissolve away—of faces, and even of entire figures, all under conditions which render imposture impossible. Both visible and invisible phantoms have had their objectivity proved by being photographed, and this has been done by experts who are above suspicion and under conditions which render the reality of the phenomena demonstrable. Both hands, feet, and faces of these phantom forms have produced moulds in melted paraffin, again under conditions which render imposture on the part of the mediums out of the question.

Yet another and final series of phenomena, which may be termed psychological or spiritual, are the seeing of spirits or spiritual forms invisible to others, hearing their voices, and by this means obtaining knowledge of circumstances occurring at a distance; or of facts unknown to any one present, but afterwards verified; or of future events which afterwards happen as predicted—of all of which there is ample evidence. Persons gifted with this power often give long and eloquent addresses, or have elaborate essays written through their hands, but without any conscious mental agency on their part; and it is from these communications that we acquire our most complete knowledge of the teaching and philosophy of modern spiritualism.

Some Characteristics of Mediums.—These numerous distinct classes of phenomena exhibit endless modifications in detail with different mediums, and there are several important considerations which are inconsistent with their being, to any considerable extent, due to imposture. In the first place, almost every medium exhibits his powers in youth or even in childhood without any opportunity of learning the methods employed by professional conjurers. In the second place, each medium exhibits a considerable individuality, and rarely, perhaps never, offers an exact reproduction of the phenomena occurring with other mediums. In the third place, all the phenomena occur sometimes in private houses, to which the medium comes without any apparatus whatever. In the fourth place, every class of phenomena has occurred with unpaid mediums, as well as with those who make mediumship a profession. And lastly, many of the most remarkable mediums have submitted to elaborate and careful tests by scientific and intelligent observers with results wholly beyond the powers of professional conjurers.

Notable Investigators of the Phenomena.—In order to appreciate the important bearing of such investigations on the theory that the whole body of spiritualistic phenomena are due to delusion or imposture, a few of the best known of these inquirers must be referred to. Perhaps the earliest scientific investigator was Dr Robert Hare (q.v.) of Philadelphia, an eminent chemist, especially known for his invention of ingenious apparatus. He, like all other earnest and patient inquirers, began under the impression that he would be able to expose a delusion; but all his experiments and tests, with apparatus of his own devising, proved that he had to deal with a great reality. He accordingly tried to induce the legislature to appoint a committee to examine and report on the experiments, and failing to succeed in this published his results in a volume entitled *Experimental Examination of the Spiritual Manifestations*.

Judge Edmonds, one of the most acute and painstaking of American lawyers, devoted years to a thorough examination of the phenomena, with the assistance of the most intelligent men of science and education among his acquaintance. He himself became a medium, as did his daughter; and this young lady, though possessing only the ordinary American school acquirements, was able when in a trance to speak many foreign languages, including modern Greek, and to hold conversations in them with natives.

Professors Mapes and Loomis, both chemists, assisted by two physicians and other friends, tested the Davenport brothers, and found that the phenomena occurring with them were in no way due to conjuring. This verdict was confirmed by many inquirers in England, among others by the late Sir Richard Burton, the last man to be imposed upon by conjuring, and to endorse it as reality. Yet he says, in a published letter, 'I have now witnessed four of the so-called dark

These were all in private houses—one of them in my own lodgings. We rejected all believers, and chose the most sceptical and hard-headed of our friends and acquaintances, some of whom had prepared the severest tests. We provided carefully against all possibility of confederates, and brought our own cords, sealing-wax, tape, diachylon, musical instruments, and so forth. . . . Sparks of red and pale fire have fallen from the ceiling, sometimes perpendicularly, at other times crossing the room. Mr Fay's coat was removed whilst he was securely fastened hand and foot, and a lucifer match was struck at the same instant showing us the two gentlemen fast bound and the coat in the air on its way to the other end of the room. . . . I have spent a great part of my life in oriental lands, and have seen there many magicians. . . . I have read and listened to every explanation of the Davenport "tricks" hitherto placed before the public, and if anything would make me take that tremendous leap "from matter to spirit," it is the utter and complete unreason of the reasons by which the manifestations are explained.

Among other investigators of known integrity and ability were Robert Dale Owen and Dr Robert Chambers, who investigated the phenomena with Kate Fox in New York, while the latter was the friend of Home, and wrote for him the introductory chapter and the appendix to his *Incidents of my Life*. Dr George Sexton, an earnest secularist teacher and lecturer, was converted by phenomena occurring in his own house and through mediums who were members of his own family or personal friends; and he afterwards investigated the materialisation phenomena occurring through Miss Cook. Mr Cromwell Varley, the electrician, tested the same phenomena by means of electrical apparatus. Dr Lockhart Robinson, after a long experience in the treatment of the insane, and having been a violent opponent of spiritualism as wholly founded on imposture and delusion, was converted by phenomena occurring in his own house in the presence of the American medium Squire. Professor Zollner of Leipzig, in his work *Transcendental Physics*, has described the most marvellous phenomena occurring in his own study and under the strictest test conditions, in the presence of the medium Slade with some of his fellow-professors as witnesses. And we have Sir William Crookes, one of the first chemists and physicists in Europe, who for several years (from 1870 to 1874) devoted a considerable portion of his time to the investigation of the phenomena, and had the courage to make public these experiments and their results. With several different mediums, in his own house and subject to the conditions of scientific experiment, he satisfied himself of the reality of the whole range of the phenomena here briefly described. In 1889 he published his notes of sances with Mr Home, in the introductory observations to which he makes this important statement: "Their publication will at any rate show that I have not changed my mind; that on dispassionate review of statements put forth by me nearly twenty years ago I find nothing to retract or to alter. I have discovered no flaw in the experiments then made, or in the reasoning I based upon them."

The Value of these Phenomena.—In view of this long series of investigations by men of special training in science and of the highest reputation, spiritualists urge that the facts on which their beliefs are based are proved to be realities beyond all reasonable doubt. It may be asked, however, as many do ask, what is the meaning or the use of these strange phenomena? We feel no interest in moving furniture, floating bodies, fire-tests, or slate-writing. The answer is that to a very large

number of minds these physical phenomena, however low and trivial they may seem, are the most effectual and often the only means of compelling attention to the subject, and this is more particularly the case with those imbued with the teachings of modern science. The moment such persons are really convinced that physical phenomena occur which they have always held and declared to be impossible, they see that there is something more in the matter than imposture or delusion, and further inquiry shows them that this class of facts constitute the mere outskirts of the subject. Almost all the agnostics and students of physical science who have become spiritualists—and they are to be counted by hundreds in every civilised country—have begun the investigation because they have been convinced that some of these lower physical phenomena are realities; and this fact is a complete answer to those who urge that such phenomena are trivial, degrading, and unspiritual. If they are so, it shows that men of the highest education and greatest knowledge are attracted by these very qualities.

The Teaching and Philosophy of Spiritualism.—But whenever we pass beyond these phenomena, and carefully examine the teachings and the philosophy to be found in the deliverances of automatic writers and trance-speakers, as well as in the normal writings of those who have long accepted and thoroughly assimilated these teachings, we enter upon a phase of the subject which no unprejudiced person will pronounce to be either useless or commonplace. The universal teaching of modern spiritualism is that the world and the whole material universe exist for the purpose of developing spiritual beings—that death is simply a transition from material existence to the first grade of spirit-life—and that our happiness and the degree of our progress will be wholly dependent upon the use we have made of our faculties and opportunities here. It is urged that the present life will assume a new value and interest when men are brought up not merely in the vacillating and questionable belief, but in the settled, indubitable conviction, that our existence in this world is really but one of the stages in an endless career, and that the thoughts we think and the deeds we do here will certainly affect our condition and the very form and organic expression of our personality hereafter.

As an example of the teaching of modern spiritualism as actually given through one of the most trustworthy mediums, the following passages from *Spirit Teachings*, by 'M.A., Oxon.' (W. Stainton Moses, 1883; memorial ed. 1898), must here suffice:

As the soul lives in the earth-life, so it goes to the spirit-life. Its tastes, its predilections, its habits, its antipathies, they are with it still. It is not changed save in the accident of being freed from the body. The soul that on earth has been low in taste and impure in habit does not change its nature by passing from the earth-sphere any more than the soul that has been truthful, pure, and progressive becomes base and bad by death. . . . The soul's character has been a daily, hourly growth. It has not been an overlaying of the soul with that which can be thrown off; rather it has been a weaving into the nature of the spirit that which becomes part of itself, identified with its nature, inseparable from its character. It is no more possible that that character should be undone, save by the slow process of obliteration, than that a woven fabric should be rudely cut and the threads remain intact. Nay more; the soul has cultivated habits that have become so engrained as to be essential parts of its individuality. The spirit that has yielded to the lusts of a sensual body, becomes in the end their slave. It would not be

happy in the midst of purity and refinement. It would sigh for its old haunts and habits. They are of its essence.'

'Immutable laws govern the results of deeds. Deeds of good advance the spirit, whilst deeds of evil degrade and retard it. Happiness is found in progress, and in gradual assimilation to the God-like and perfect. The spirit of divine love animates the acts, and in mutual blessing the spirits find their happiness. For them there is no craving for sluggish idleness, no cessation of desire for progressive advancement in knowledge. Human passions and human needs and wishes are gone with the body, and the spirit lives a life of purity, progress, and love. Such is its heaven. We know of no hell save that within the soul: a hell which is fed by the flame of unpurified and untamed lust and passion, which is kept alive by remorse and agony of sorrow, which is fraught with the pangs that spring unbidden from the results of past misdoings; and from which the only escape lies in retracing the steps and in cultivating the qualities which bear fruit in love and knowledge of God.'

'We may sum up man's highest duty as a spiritual entity in the word Progress—in knowledge of himself, and of all that makes for spiritual development. The duty of man considered as an intellectual being, possessed of mind and intelligence, is summed up in the word Culture in all its infinite ramifications, not in one direction only, but in all; not for earthly aims alone, but for the grand purpose of developing the faculties which are to be perpetuated in endless development. Man's duty to himself as a spirit incarnated in a body of flesh is Purity in thought, word, and act. In these three words, Progress, Culture, Purity, we roughly sum up man's duty to himself as a spiritual, an intellectual, and a corporeal being.'

It is a very important fact that Sir William Crookes, F.R.S., at the conclusion of his address as president of the British Association in 1898, gave his testimony to the truth and importance of spiritualism in those weighty terms: 'Upon one other interest I have not touched—to me the weightiest and the farthest reaching of all.' And farther on he declares: 'I have nothing to retract. I adhere to my already published statements. Indeed, I might add much thereto.' These words may, perhaps, induce readers of this article carefully to peruse the *Researches* of one of the greatest physicists of his day before condemning modern spiritualism as a worthless subject of study.

Spitalfields, in north-east London, derives its name from the *hospital* of St Mary, founded there in 1197 by Walter Brune and his wife Rosia. Silk-

weaving was established by French emigrants after the revocation of the Edict of Nantes (1685).

Spithead, a celebrated roadstead, and a favourite rendezvous of the British navy, is the eastern division—the Solent (q.v.) being the western—of the strait between the Isle of Wight and the mainland of England. It is protected from all winds, except the south-east, and its security gained it the sailors' name of the 'king's bed-chamber.' Here in 1797 the sailors of the Channel Fleet mutinied for more liberal pay and allowances, which were granted to them. Spithead has been strongly defended since 1864 by fortifications completing those of Portsmouth (q.v.). The 'Spit' is a sandbank stretching south from the Hampshire shore for 3 miles.

Spitsbergen is a group of Arctic islands lying about 400 miles N. of Norway and covering some 25,000 square miles. The chief islands are West Spitsbergen, North-East Land, Barents Land, Edge Island, Prince Charles Foreland, and the Wyches Islands or King Charles Land. With Bear Island, 130 miles S., these islands are known collectively in Norway as Svalbard. Spitsbergen is a much-dissected plateau rising to sharp peaks, whence the name, in the west, and comparatively flat-topped mountains farther east. The peaks generally average some 2000 feet, but Mount Newton in New Friesland is 5445 feet, Hornsund Tind, in the south, 4690 feet, and Mount Monacob on Prince Charles Foreland, 3450 feet. Glaciers occupy most of the valleys and generally reach the sea, but North-East Land alone has a true ice-cap. The coasts are much indented and long fjords penetrate the larger islands. The western coasts, owing to the influence of the North Atlantic drift, are generally clear of pack-ice, but the eastern shores, washed by a cold current from the Arctic Ocean, are usually difficult of access. The north coast is intermittently open and closed by ice. Climate is cold in winter, but frequently less cold than eastern Canada; in summer it is mild and not unlike that of the Shetlands. Vegetation is a scanty form of tundra, which may, however, be luxuriant in places. A creeping willow and a dwarf birch, a few inches high, are the only trees; for the rest the plants are saxifrages, buttercups, poppies, &c., and many mosses and lichens. There are 128 species of flowering plants. Reindeer, fox, and polar bear are found. Many sea-birds breed in summer, but the ptarmigan and snowy owl alone stay in winter. In the waters are seals, walrus, whales, and many fish. Spitsbergen was discovered by Barents, a Dutchman, in 1596, but probably had been sighted in 1194 by the Norsemen and named Svalbard. In the 17th century it was frequented by British, Dutch, and Basque whalers. Later it became the resort of Russian and afterwards Norwegian trappers. Although Britain and Holland made rival claims to Spitsbergen in the early whaling days, the question of sovereignty did not become an important issue before the discovery of valuable minerals in the end of last century. After several abortive conferences on the subject the sovereignty of Spitsbergen and Bear Island was assigned to Norway in 1920 by the Supreme Council. Norwegian control became effective in August 1925. The treaty safeguards the right of other nations in mining and trade. Spitsbergen is estimated to contain over 8,000,000,000 tons of coal of Carboniferous, Cretaceous, and Tertiary ages. This coal is being mined by Norwegian, British, Dutch, and Swedish companies. Mines on Bear Island have been abandoned. Mining camps exist in Advent Bay, Green Harbour, King's Bay, near Coles Bay, and elsewhere. The total export in 1925 was about 400,000 tons, to

Norway, Sweden, and Russia. Gypsum, asbestos, and zinc ore also occur. There is wireless communication with Europe and a summer postal service. Vessels cruising with tourists visit Spitsbergen every summer. The population of miners and hunters numbers about 2000.

See Sir M. Conway, *No Man's Land* (1906); Rudmose Brown, *Spitsbergen* (1920); G. Binney, *With Ski and Sledge on Arctic Glaciers* (1925), and *Norway Year Book*.

Spitteler, KARL FRIEDRICH GEORG, was born 24th April 1845 at Liestal, in the country canton of Basel, and studied law, then theology at Basel, Zürich, and Heidelberg. After spending some years in Russia as a tutor in a general's family, he returned home in 1879 and took up, first, teaching, then journalism. In 1892, however, he retired with his wife and family to Lucerne, where he died 29th December 1924. Spitteler's chief literary accomplishment is his great mythological epic, *Der Olympische Frühling* (1900-1903), displaying, as does most of his work, a rare originality of genius, and in parts carrying the mind back to Dante. The most influential impulse, however, he owed to French poetry. His other works include *Prometheus und Epimetheus* (1880-81), *Eckermannsdrama* (1886), *Schmetterlinge* (1886), *Balladen* (1895), several tales (*Friedli der Kolderi*, *Gustav*, *Konrad der Leutnant*, &c.), and *Meine frühesten Erlebnisse* (1914).

Spitz, or POMERANIAN DOG, the result of a cross from the Eskimo dog, the native dog of the Arctic regions. The spitz is about the size of the spaniel, with a sharp-pointed face and an abundant white coat sometimes of great beauty. Other colours are known, including black. It is comparatively common in the United States, where it is a favourite dog with Germans especially.

Splay. See CHAMFER.

Spleen. This organ, present in vertebrates from the fishes upwards, has no doubt very important functions to perform, but about these we know as yet very little indeed. In man it is about 5 inches in length, and is situated in the left hypochondriac region, adapted to the cardiac portion of the stomach (see figure at article ABDOMEN). Unlike the liver and pancreas, it has no duct and manufactures no juice, being connected with the rest of the body by its blood-vessels, nerves, and lymphatics: these enter the organ at its hilum and ramify within it. The spleen is invested by a capsule consisting chiefly of muscular tissue, and from this capsule muscular processes called trabeculae run into the interior of the organ supporting its delicate pulp. As one would expect from its structure, the organ can expand and contract, and this it does from a variety of causes—for instance, after a meal the organ expands, reaching its maximum in about five hours, then contracting again. In diseased conditions it may expand to many times its normal size, which would not be possible were its capsule of fibrous tissue like those of other glands. The blood-vessels enter the spleen, and the arteries become invested by curious masses of tissue called adenoid, and these little masses, the splenic corpuscles, are of about the size of millet seed, and quite visible to the naked eye on cutting open the organ.

If the spleen of a man or an ox be cut open it will appear of a soft pulpy consistence and deep crimson in colour, with little white patches, these splenic corpuscles, scattered through it. On putting the spleen under a running jet of water the soft spleen pulp infiltrated with blood will be washed away, leaving behind the tough capsule, the branching trabeculae, and the blood-vessels with

some of these splenic corpuscles attached to them. The blood-vessels end in the tissue of the spleen, and those that terminate within the splenic bodies do so in the usual way, passing into true capillaries. Within the spleen pulp, however, which forms the chief part of the organ, the arteries open directly into the loose tissue forming the pulp, so that the blood percolates through this before leaving the organ by the veins. The blood thus becomes intimately associated with this pulpy tissue, and becomes modified by it, as we shall see. It is highly probable that the chief use of the spleen is to modify the blood passing through it, and hence it is spoken of as a blood-gland, in contradistinction to a digestive gland, which pours its secretion into the digestive tract, and aids the processes which go on there. It is very probable that the spleen has the power of arresting and destroying the old worn-out red blood-corpuscles as they pass through it, for within the spleen itself evidence of their destruction is found in the large quantity ever present of iron and other bodies, which would result from their dissolution. Moreover there is strong reason for supposing that the active agents in this destruction are the cells present in the spleen pulp, some of which are generally found with bits of the red blood-corpuscles, and pigmented masses derived from them, within their bodies. But the spleen not only destroys blood-corpuscles; under some conditions it forms new corpuscles, and these enter the splenic vein, and are carried off in the general circulation. Most of these new corpuscles appear to be of the white variety, for an abnormally large number of these are by some observers found in the splenic vein; in early life, and under some conditions in adult life, the spleen appears to form red corpuscles also.

There is little doubt that in a general way the spleen is a blood-modifying gland, and in diseases such as splenic leucocytæmia it becomes enormously enlarged, and produces large numbers of white corpuscles. In malaria it may become also enormously enlarged, forming the ague-cake. It may, however, be excised, even in the case of man, without producing fatal consequences, the lymphatic glands enlarging and the bone marrow undergoing changes, probably to enable them to compensate for the loss of the other organ.

The spleen was long supposed to be the seat of some of the less amiable emotions—envy, malice, &c.

Spleenwort, any fern of the genus *Asplenium*. See FERNS. Vol. IV. p. 619.

Splenic Fever. See ANTHRAX.

Splicing. See KNOTS.

Splint is a bony enlargement on the horse's leg, between the knee and fetlock, usually appearing on the inside of one or both forelegs, frequently situated between the large and small canon bones, depending upon concussion, and most common in young horses that have been rattled rapidly along hard roads before their bones are consolidated. When of recent and rapid growth, the splint is hot and tender, and causes lameness, especially noticeable when the horse is trotted along a hard road. A piece of spongiopiline saturated with cold water should be applied to the splint, kept in position with a light linen bandage, and wetted with cold water or a refrigerant mixture every hour. Perfect rest must be enjoined for ten days or a fortnight. When the limb is cool and free from tenderness, the enlargement, which will still remain, may be greatly reduced by some stimulating applications, such as the ointment of the red iodide of mercury, the common fly-blister, or the firing-iron. For the splint-bones, see HORSE.

Splints, in Surgery, are certain mechanical contrivances for keeping a fractured limb in its proper position, and for preventing any motion of the ends of the broken bone; they are also employed for securing perfect immobility of the parts to which they are applied in other cases, as in diseased joints, after resection of joints, &c.

Ordinary splints are composed of wood cut to the size of the limb, and padded; pads are usually made of non-absorbent cotton-wool, bound lightly to the splints by loose-woven cotton bandages, by sheets, &c.; and the bony prominences of the limbs are further protected by nests of wool. The splints should be firmly bound to the limb with pieces of bandage, or with straps and buckles; care being taken that they are put on sufficiently tight to keep the parts immovable, and to prevent muscular spasm, but not so tight as to induce discomfort. Gutta-percha, sole-leather, or pasteboard, after having been softened in boiling water, may in some cases advantageously take the place of wooden splints. They must be applied when soft to the part they are intended to support, so as to take a perfect mould, and then be dried, stiffened, and, if necessary, lined. Perforated tin or aluminium is often used to form splints. An account of the more complicated kinds of splint required in certain cases, as Macintyre's Splint, Liston's Splint, &c., may be seen in any illustrated catalogue of surgical instruments.

The ordinary splint is now to a great degree superseded by immovable bandages, which consist of the ordinary bandage saturated with a thick mucilage of starch, with glue, or with water-glass (a solution of silicate of soda). As, however, these bandages require some hours to dry and become rigid, means must be used to counteract any displacement of the limb in the interval. On this account many surgeons prefer the plaster of Paris or gypsum bandage, which is applied in the following manner: the limb being protected by a layer of cotton-wool, a bandage composed of coarse and open material, into which as much dry powdered gypsum as possible has been rubbed, must be immersed in water for about a minute, and then rolled around the limb in a spiral manner, just as an ordinary bandage; after every second or third turn of the bandage, the left hand of the surgeon should be plunged into water, and smeared over the part last applied. When the whole has been thus treated, the exterior of the bandage should be smeared over with a paste of gypsum and water until a smooth surface and complete rigidity have been attained—a process not occupying more than about a quarter of an hour.

Split. See SPALATO.

Spitgen, an Alpine pass in the Grisons, Switzerland, situated at an altitude of 6946 feet. It connects the valley of the Farther Rhine with that of a tributary of the Adda, and has been used for crossing the Alps since the time of the Romans. The existing road, 24 miles long and 14½ feet wide throughout, was completed by the Austrian government in 1823. It is protected against avalanches by several galleries and refuges.

Spodumene, a mineral consisting of silicate of lithium and aluminium, crystallising in the monoclinic system; hardness 6½-7; sp. gr. about 3.16. Some varieties rank as gem-stones.

Spohr, **LUDWIG**, composer and violinist, was born at Brunschwiek on 6th April 1784. His talent for music was shown early, and attracted the notice of the duke, who lent him valuable support in his studies. This patronage he justified by establishing a high reputation as a performer on the violin. In 1805 he was appointed music director at the court of Saxe-Gotha, but gave

up that post in 1813 to become music director of the Theater an der Wien at Vienna. There, however, he stayed only two years, and afterwards spent a similar period (1817-19) in a similar position at Frankfurt-on-the-Main. In 1820 he appeared in London, where he was received with great applause at the Philharmonic Society's concerts. On the recommendation of Weber, he was in January 1822 appointed Kapellmeister at the court of Hesse-Cassel, which post he continued to hold till 1857. He died on 22d October 1859. The best of his numerous musical compositions are the operas *Faust*, *Jessonda*, and *Zemira und Azor*; the oratorios *Die letzten Dinge*, *Des Heilands letzte Stunden*, and *Der Fall Babels*; nine grand symphonies, the finest *Die Weihe der Töne*; fifteen very highly esteemed violin concertos; besides sonatas for violin and harp, fantasias, and rondos. *Die letzten Dinge*, or *Last Judgment*, is a very grand and attractive work; so also is *Der Fall Babels*, first produced at a Norwich musical festival (1842). As a violinist Spohr deservedly ranks as one of the greatest amongst German masters of the instrument. His *Violinschule*, a manual for advanced violin-players, is almost indispensable for any student who aspires to mastery of technique as a performer.

See his Autobiography (Eng. trans. 1864), and biographies by Mahbran (1860) and Schletterer (1881).

Spoils System. See JACKSON (ANDREW).

Spokane, a city of Washington, capital of Spokane county, is situated on the Spokane River and on several important railroads. The falls on the river are utilised for mechanical and electric power, and have added greatly to the importance of the town, which has many flour and lumber mills, foundries, machine-shops, car and furniture works, potteries, and is a great mining centre. In 1890 it was almost totally destroyed by fire, but quickly rebuilt, and has grown very rapidly. Pop. (1880) 350; (1890) 19,922; (1900) 36,848; (1910) 104,402; (1920) 104,437.

Spoleto (Lat. *Spoletinum*), an archiepiscopal see of Umbria, is situated on a rocky hill, 88 miles by rail N. by E. of Rome. It is commanded by a citadel (now a prison) which dates from the Gothic period, and has a fine cathedral, built under the Lombard dukes, with frescoes by Filippo Lippi. The church of S. Pietro, outside the town, has a façade with curious sculptures of 1000 and 1200, and the churches of SS. Domenico, Gregorio, and Nicolò are all of interest. Almost contemporary frescoes depicting the murder of St Thomas à Becket have been discovered. At the cemetery is the old church of S. Salvatore (4th century) and close by is S. Ponziano (13th century). There is a good museum, and the whole town is very picturesque, and still mediæval in aspect. There are a large number of Roman ruins in and under the town in good preservation—a theatre, an amphitheatre, a bridge, a triumphal arch of Drusus and Germanicus, a temple, the house of Vespasia Polla, the mother of the Emperor Vespasian, &c. There are traces of two different enclosures—pre-Roman (?) and Roman. The aqueduct which supplies the city is Roman in origin, but was restored in 604 and 1364, to which latter date the whole of the present Ponte delle Torri belongs; the aqueduct is 270 feet high and 680 long. The ancient *Spoletinum* had its origin in a Roman colony planted here in 242 B.C.; Hannibal (q.v.) was repulsed in an assault he made on the town (217 B.C.) after the battle of Lake Trasimene. It was an important position during the wars of the Vandals and the Goths; and under the Lombards it became the capital of an independent duchy, and its dukes ruled over great part of Central Italy. Having

been united to Tuscany, it was bequeathed by the Countess Matilda to the pope (1115). Spoleto has manufactures of woollens and hats. Pop. (1921) 28, 289.

Sponges (*Porifera*), a class of animals whose type of structure is simpler than that of all the other multicellular forms or Metazoa. For the body of a sponge is not differentiated into organs; and tissues are only, as it were, in the making. Almost all are marine, occurring from the shore to the great depths. Except as embryos, they are always fixed to rocks, or in the mud, or upon seaweeds, or on other animals. Their sedentary life, the usual absence of any marked contractility, their frequently herb-like growth, and other characters, led early naturalists to regard sponges as plants; but their animal nature is at once evident when we examine into their internal structure and activities, or when we trace their development. Yet they remained puzzles for centuries. Peyssonnel regarded them as worm-nests, for were not worms found inside of them? Lamarck thought they were colonies of polypes, but the polypes were not to be seen. In popular classification they were ranked with seaweeds. A great step was made when, about 1820-25, Robert Grant observed the water-currents which pass in by minute pores all over the surface and pass out by the larger apertures. Since then our knowledge of sponges has been rapidly progressive.

If we examine a very simple sponge, such as *Ascecta*, we see a small vase-shaped body, fixed at its base, open at the apex.

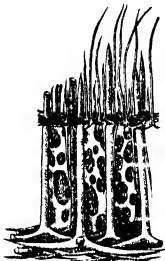

Fig. 1. Section through wall of *Syceila chrysalis*, showing needles, grape-like spicules, and inhalant pores.

Examined microscopically this vase shows an internal layer of flagellate cells, a very delicate external skin, and between these a middle stratum in which lie numerous spicules of lime, which form the supporting skeleton of the sponge. Through the walls run numerous fine canals, and if we observe a larger sponge living in water with which a little powdered carmine has been mixed we can verify Grant's observation that water passes in by minute pores all over the surface and passes out by the larger apical apertures. On these currents of water, which continually feed and refresh the body, the life of the sponge depends. Every Metazoan organism is 'a city of cells'—a sponge is peculiarly Venice-like. The currents are sustained by the activity of the internal flagellate cells, which by their ceaseless lashing draw the water inwards and drive it also outwards, and at the same time absorb food-particles which drift along in the current.

But few sponges are so simple as the vase-like *Ascecta*; we are familiar, for instance, with the complex 'horny' skeleton of the bath-sponge (*Euspongia*), or with the beautiful flinty framework of the Venus' Flower-basket (*Euplectella*); and an examination of the fresh-water sponge (*Spongilla*) of the lake or canal, or of the Mermaids' Gloves (*Chalina*) so often cast up half alive on the beach, convinces us that the structure of the soft parts is also relatively complex. Yet with the simple primitive cups the most complex forms are connected by a gradual series of steps, and simple cups they all are when very young. Let us consider briefly how the complication of structure is brought about.

(1) The vegetative character of sponges is shown by the prolific way in which buds grow out from the parent body. These buds may produce other buds, and the walls of neighbour buds may fuse; in this way there arise from an original sac-like form complex structures puzzling to those who seek logical clearness as to the nature of animal individuality (see fig. 3).

(2) In the simple *Ascon* type the internal cavity is lined by the characteristic Monad-like, 'collared,' flagellate cells. If this layer grow more

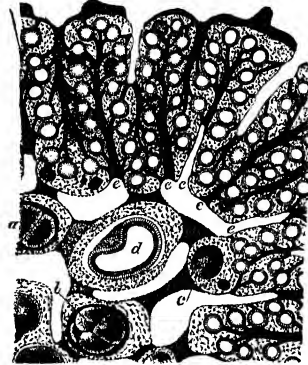

Fig. 2.—Section of part of a Sponge, *Oscarella lobularis* (after Schulze), showing afferent canals, flagellate chambers, efferent canals, internal cavities (*e, c*), segmenting ova (*a, b, c, d*).

rapidly than the outer strata it will naturally become folded into a number of side-aisles, and this is seen in the *Sycon* type of calcareous sponges, in which the characteristic collared and flagellate cells are restricted to a series of radial chambers around the central cavity. If a similar process of folding occur in the radial chambers the characteristic collared and flagellate cells become restricted to little flagellate ampullae or chambers, which afferent canals from the surface enter, and from which efferent canals lead to the central cavity and thence outwards. This is the state of affairs in the *Leucon* type of calcareous sponges, and, with further complications, in the great majority of forms.

(3) Another seat of complication is the middle stratum. This is called the mesoglea in order to emphasise the fact that in sponges, as also in *Cœlenterates*, it has not the same definiteness as the middle layer or mesoderm which occurs in the *Cœlomata*—that is, in most animals higher than *Cœlenterata*. In the simple sponges the middle stratum is very simple, and always it seems to owe its units to contributions from the inner layer. In more complex forms, however, the mesoglea contains a great variety of cells, some skeleton-making, others contractile, others like simple connective tissue, others full of pigment, others forming reproductive elements, and so on. In sponges the outer or dermal layer is relatively unimportant, though it may line the outer portions of the inhalant canals; the middle layer or mesoglea tends to show much

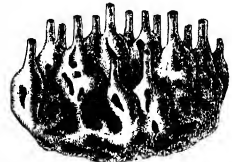

Fig. 3.—Figure of *Leucondra saccharata*, showing mode of growth by budding.

division of labour in its component elements; the inner or gastral layer consists of flagellate cells, either collared or flattened. There are serious technical difficulties in the way of calling the outer layer ectoderm and the gastral layer endoderm, as would be done in other Metazoa.

Life of Sponges.—Although sponges do not move, there is much motor activity in the lashing of the flagellate cells. Like many other passive organisms sponges are profoundly influenced by their surroundings, for their shapes vary according to the nature of their anchorage and the currents which play around them. Sensitiveness to stimulus is shown by the closure of the little superficial pores and sometimes even of the larger exhalant aperture or apertures. This closure is due to special contractile cells in the mesoglea; no specialised nerve-cells have been detected. The food of sponges consists of microscopic organisms and particles of organic debris, which are borne by the water-currents, and caught by the flagellate cells, which, like so many Monads, swallow first and digest intracellularly afterwards. From the cells which feed, surplus nutritive material oozes to adjacent cells, or is passed to mobile amoeboid cells in the mesoglea. Useless debris is also got rid of by the collared cells. Respiration is of course effected by the currents of water which wash the cells, and some of the bright pigments, such as floridone, characteristic of many sponges, readily absorb oxygen. The green colour of Spongilla is due to partner-Algae with chlorophyll.

Reproduction.—Sponges multiply, like many plants, by overgrowth and budding, but the buds remain continuous with the parent mass, though sometimes it happens that small portions are set adrift from a moribund body. As a sponge is but slightly differentiated, as a fragment is a fair sample of the whole body, we can understand the success with which the sponge-farmers bed out portions of sponge in suitable places, leaving them to grow to a size fit for use. But sexual reproduction also occurs in all sponges. The ova and spermatozoa are included in the mesoglea, originating from apparently similar cells. Both unisexual and bisexual forms occur, in rare cases within one species. The ova are fertilised by spermatozoa drawn in by the water-currents, and development proceeds through several stages before the embryo leaves the parent (see fig. 2).

The life-history of the fresh-water sponge, Spongilla, as told by Marshall, is one of interesting vicissitudes. In autumn the sponge begins to suffer from the cold and the scarcity of food, and dies away. But throughout the moribund parent clumps of cells combine into 'gemmules,' which are furnished with capstan-like spicules, and are able to survive the winter. In April or May they float away from the parental corpse, and form new sponges. Some of these are short-lived males, others are more stable females. The ova produced by the latter, and fertilised by the cells of the former, develop into another generation of sponges, which in turn die away in autumn, and give rise to gemmules. The life-history

thus illustrates Alternation of Generations (q.v.).

Development.—The development of sponges varies

considerably in the different types, but we may sketch that of a calcareous sponge. The fertilised ovum divides completely, and forms a hollow sphere of in part flagellate cells, which escapes from the parent into the water. In the course of a short free-swimming life the ball of cells becomes invaginated, and forms a two-layered gastrula. This fixes itself, mouth downwards. But pores soon appear through the walls; the internal cells which had meanwhile lost their lashes regain them; an exhalant orifice is formed by rupture at the apex; a middle stratum is derived from the inner layer and begins to form spicules: the young sponge is made.

Classification.—One of the oldest and most convenient classifications of sponges is that which distinguishes three main sets according to the nature of the skeleton:

(1) **CALCAREONIAE:** with spicules of carbonate of lime, including Acon, Sycon, and Leucos types. The pause-like *Grantia compressa* is common on British shores.

(2) **SILICISPORIAE:** with spicules and threads of silica—e.g. the Venus' Flower-basket (*Euplectella*); the likewise deep-sea, Glass-rope Sponge (*Hyalonema*); Mermaid's Glove (*Chama octata*), with a fibrous as well as a finny skeleton; the common Crumb-of-bread Sponge (*Halichondria panicea*); Chone, which bores in oyster shells; *Siderites domuncula*, which grows round a wreck shell inhabited by a hermit-crab; and the fresh-water Spongilla.

(3) **CECATHOSPONGIAE:** with a framework of spongin or spongeskin and no proper spicules—e.g. the Bath-sponge (*Euspongia*), which thrives on some of the Mediterranean coasts.

To these may be added a few, probably degenerate, forms which have no skeleton at all (*Myxospongiae*)—e.g. *Oscarella* (or *Halsarcea*) *lobularis*.

History.—Sponges, as we should expect, occur in very ancient strata; remains of a flinty form (*Protospongia*) have been found in Cambrian strata. In succeeding ages they are almost always represented. Remains of calcareous forms are almost confined to one peculiar set of large forms (*Pharetronies*) in Devonian and several succeeding epochs. Professor Franz Eilhard Schulze the greatest authority on sponges—divided the sponge branch of the genealogical tree into three: the calcareous forms to one side, the siliceous Hexactinellida with triaxial spicules to the other, and between these the other flinty sponges whose spicules have four axes (*Tetraxonina*) or only one (*Monaxonina*), and the horny sponges without any spicules. It is generally allowed that the sponges are quite distinct from the Coelenterates, and that they are somewhat degenerate and divergent descendants of the primitive Metazoa.

Relation to other Organisms.—Sponges are living thickets in which many small animals play hide-and-seek. Polypes, worms, and some other animals are often found associated with sponges, using them partly for shelter, partly as browsing-grounds. From the appetite of larger animals sponges are doubtless in great part saved by their spicules, and their frequently offensive taste and odour. Some sponges are borers, and others smother forms of life as passive as themselves. Several crabs are masked by growths of sponge, and within several sponges minute Algae live in constant partnership.

Several species of Euspongia are in use for economic purposes. Two species are brought from the Levant, and one (not much inferior) from the West Indies and coast of Florida. The trade in sponge is very considerable; it is carried on chiefly by Greeks, Sicilians, Tripolitans, Tunisians, and Bahama Islanders. The Levantine boats find their chief employment on the coasts of Crete, Barbary, and Syria. The sponge is obtained by diving, the diver taking down with him a flat piece of stone of a triangular shape, with a hole drilled through one of its corners; to this a cord from the boat is attached, and the diver makes it serve to guide him to particular spots. When he reaches the grow-

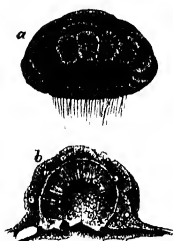

FIG. 4.—Two stages in the development of *Spondra raphanus* (after Schulze):

a, gastrula, towards end of free-swimming stage; b, section of embryo after it has settled down, showing the two germinal layers and the central cavity.

ing sponges he tears them off the rocks, and places them under his arms; he then pulls at the rope, which gives the signal to his companions in the boat to haul him up. The diving-bell and diving-dress are sometimes made use of. The Greeks of the Morea, instead of diving, obtain sponges by a pronged instrument; but the sponges thus collected are torn, and sell at a low price. The best sponges are obtained on detached heads of rock in eight or ten fathoms of water.

The sponges of the West Indies are larger and coarser. The sponges are torn from the rocks by a fork at the end of a long pole. To get rid of the animal matter they are buried for some days in the sand, and then soaked and washed. Sponge-culture has been tried off Florida and elsewhere.

The domestic uses of sponge are familiar to every one. It is also of great value to the surgeon, not only for removing blood in operations, but for checking hæmorrhage. Burnt sponge was once a valued remedy for scrofulous diseases and goitre; but iodine and bromine, from which it derives all its value, are now administered in other forms. The heads of drumsticks for playing the timpani are covered with sponge.

See the account of sponges by Sollas in the *Cambridge Natural History* (1906); the article in Lydekker's *Zoology* (1900); Haeckel, *Die Kalkschwämme* (1872); *Challenger Reports on Sponges*, by Haeckel, Poléjoff, Schulze, Sollas; Vosmaer, 'Die Poriferen,' in Bronn's *Thierreich*; Bowerbank's *British Spongiada*; Hinde's *Fossil Sponges*.

Spongilla, a genus of Sponges (q.v.) inhabiting fresh water.

Spongy Parenchyma, a loose tissue forming the inner part of the under side of a leaf. It is full of intercellular air-spaces, which communicate with the atmosphere through stomata in the epidermis. Above it is ordinarily a layer of palisade-cells.

Spontaneity. See NERVOUS SYSTEM, WILL.

Spontaneous Combustion is a phenomenon that occasionally manifests itself in mineral and organic substances. For some facts connected with the spontaneous ignition of mineral substances, see PYROPHORUS. Ordinary charcoal does not undergo combustion in air below a temperature of 1000°, but in some states, especially when impregnated with oil, it is liable spontaneously to acquire a temperature which may lead to unexpected combustion. There have been many instances of the spontaneous ignition of coals containing iron Pyrites (q.v.) when moistened with water. The pyrites which most readily give rise to spontaneous combustion are those in which the protosulphide is associated with the bisulphide of iron; and these occur among the Yorkshire coals and in some kinds of South Wales coal. Sulphur has no tendency to spontaneous combustion, but Dr Taylor refers to an instance that came to his own knowledge, in which there was reason to believe that the vapour of bisulphide of carbon in an india-rubber factory was ignited by solar heat traversing glass. Phosphorus, when in a dry state, has a great tendency to ignite spontaneously, and it has been observed to melt and take fire (when touched) in a room in which the temperature was under 70°. The ordinary lucifer-match composition is luminous in the dark in warm summer nights, which shows that oxidation, and therefore a process of heating, is going on. Hence large quantities of these matches kept in contact may produce a heat sufficient for their ignition. 'I have seen them ignite,' says Dr Taylor, 'as a result of exposure to the sun's rays for the purpose of drying.'

In organic substances, apart from the accidents that may result from the admixture of strong nitric

or sulphuric acid with wool, straw, or certain essential oils, which, if they occur, are immediate and obvious, there are many cases in which, 'without contact with any energetical chemical compounds, certain substances—such as hay, cotton and woody fibre generally, including tow, flax, hemp, jute, rags, leaves, spent tan, coconut fibre, straw in manure-heaps, &c.—when stacked in large quantities in a damp state, undergo a process of heating from simple oxidation (ereumcausis) or fermentation, and after a time may pass into a state of spontaneous combustion' (Taylor). Cotton, woollen articles, hemp, tow, and flax impregnated with oil, when collected in large quantity, are specially liable to ignite spontaneously; and the accumulation of cotton-waste, used in wiping lamps and the oiled surfaces of machinery, has more than once given rise to accidents, and led to unfounded charges of incendiarism. Dr Taylor relates a case in which a fire took place in a shop 'by reason of a quantity of oil having been spilled on dry sawdust.' According to Chevallier, vegetables boiled in oil furnish a residue which is liable to spontaneous ignition. The great fire at London Bridge in 1861 was referred to the spontaneous combustion of jute in its ordinary state; but Dr Taylor remarks that this is wholly incredible, and from experiments which he made for the defendants in the case of Hepburn v. Lordan (1865), and on other grounds, he holds that there is even no evidence of moist jute undergoing spontaneous combustion. Dry wood is supposed by Chevallier and some other chemists to have the property of igniting spontaneously. Deal which has been dried by contact or contiguity with flues or pipes conveying hot water or steam at 212° is supposed to be in a condition for bursting into flame when air gets access to it; and the destruction of the Houses of Parliament, and many other great fires, have been ascribed to this cause; but it appears that some amount of charring is necessary, and that on slight cooling a considerable quantity of oxygen is absorbed from the air, which induces a sufficient rise of temperature to set up spontaneous combustion. In a case recorded in the *Annales d'Hygiène* for 1841, MM. Chevallier, Ollivier, and Devergie drew the conclusion that a barn had caught fire from the spontaneous combustion of damp oats which were stored in it. No such cases are known to have occurred in Great Britain. See also FIRE and GUN-COTTON.

Spontaneous combustion of the human body is supposed to have occurred in a number of recorded cases, of which one of the earliest was that of Mme. Millet at Reims in 1725, and one of the most notable that of a man found burning in bed in 1847 (*Gazette Médicale*, 4th September 1847). Some of the alleged cases have been traced to wilful burning after murder; some are plainly incredible; the remainder, with the exception of the 1847 case, which remains unexplained, can all be traced to the destruction of the bodies of intoxicated brandy-drinkers, near an open fire in winter, with no one present and no evidence forthcoming as to the time occupied in the combustion, or as to the circumstances, other than intoxication, preceding the combustion. Liebig discusses the subject in his *Letters on Chemistry*, and concludes that, while a fat dead body charged with alcohol may perhaps burn, a living body, in which the blood is circulating, cannot take fire under any circumstances.

For further details the reader is referred to Graham's 'Report on the Cause of the Fire in the *Anazon*,' in the *Quarterly Journal of the Chemical Society*, vol. v. p. 34; to the article 'Combustion' in Watts's *Dictionary of Chemistry*, vol. i.; and to the elaborate chapter on this subject in Taylor's *Principles and Practice of Medical Jurisprudence*. For spontaneous combustion

in the human body, see the articles thereon in the Medical Encyclopaedia; the preface to Dickens's *Bleak House*; Liebig's *Lectures on Chemistry*; Dupuytren's *Leçons Orales*; Taylor's *Medical Jurisprudence*.

Spontaneous Generation is a term applied to the real or imaginary development of lowly organisms from non-living matter. The facts are that when organic substance is exposed to the air it putrefies, and at the same time living animals—maggots, infusoria, and others, according to the nature and conditions of the substance—appear in it. The question is, whence do the living animals come; from the organic stuff or from germs present in it or in the air? There is a further question—what is the cause of the putrefaction; is it an ordinary process of slow oxidation or is it caused by the living organisms? If the dead organic matter can give rise to life, then we know something of the mode of origin of life upon this planet, for we can make solutions of inorganic salts that will support life, and might therefore also give origin to it; if not, then we are entirely ignorant as to that origin. For many years no one has doubted but that, if one is careful to exclude all germs from the organic stuff, no life can proceed from non-living matter, even if it has once formed part of some living organism and is in the most complex state in which such matter is known to us. The matter is therefore one of historic interest chiefly. As long ago as 1870 Huxley, in his presidential address to the British Association, was able to say that it appeared to him, within certain limitations, that the doctrine of Biogenesis, that life proceeds from life only, was victorious along the whole line. These limitations were, he said, that if he could have been a witness of the early stages of the earth's history, when the physical and chemical conditions were different from those that now hold, he would have expected to see the evolution of living protoplasm from non-living matter. As these limitations are still often thought inconsistent, and as by other people the denial of spontaneous generation seems inconsistent with a belief in evolution, it will be well to quote Herbert Spencer's reply to a critic who urged objections on this ground of inconsistency. In his *Principles of Biology* (vol. I., Appendix, 1868) he says, 'I do not believe in the "spontaneous generation" commonly alleged, and so little have I associated in thought this alleged "spontaneous generation," which I disbelieve, with the generation by evolution, which I do believe, that the repudiation of the one never occurred to me as liable to be mistaken for repudiation of the other. That creatures having *quite specific structures* are evolved in the course of a few hours, without antecedents calculated to determine their specific forms, is to me incredible. Not only the established truths of Biology, but the established truths of science in general, negative the supposition that organisms having structures definite enough to identify them as belonging to known genera and species can be produced in the absence of germs derived from antecedent organisms of the same genera and species. If there can suddenly be imposed upon simple protoplasm the organisation which constitutes it a *Paramecium* I see no reason why animals of greater complexity, or indeed of any complexity, may not be constituted in the same manner. In brief, I do not accept these alleged facts as exemplifying evolution, because they imply something immensely beyond that which evolution, as I understand it, can achieve. In the second place, my disbelief extends not only to the alleged cases of "spontaneous generation," but to every case akin to them. The very conception of spontaneity is wholly incongruous with the conception of evolution.' On the other hand he says, 'Granting that the forma-

tion of organic matter and the evolution of life in its lowest forms *may* go on under existing cosmical conditions, but believing it more likely that the formation of such matter and such forms took place at a time when the heat of the earth's surface was falling through ranges of temperature at which the higher organic compounds are unstable, I conceive that the moulding of such organic matter into the simplest types must have commenced with portions of protoplasm more minute, more indefinite, and more inconstant in their characters than the lowest Rhizopods—less distinguishable from a mere fragment of albumen than even the Protophenes of Professor Haeckel. The evolution of specific shapes must, like all other organic evolution, have resulted from the actions and reactions between such incipient types and the environment, and the continual survival of those which happened to have specialities best fitted to the specialities of their environments. To reach by this process the comparatively well specialised forms of ordinary infusoria must, I conceive, have taken an enormous period of time.' Again, 'That organic matter was not produced all at once, but was reached through steps, we are well warranted in believing by the experience of chemists. Organic matters are produced in the laboratory by what we may literally call *artificial evolution*. Chemists find themselves unable to form these complex combinations directly from their elements, but they succeed in forming them indirectly by successive modifications of simpler combinations.' We may say then that it is certain that living organisms, large enough to be visible with the help of a microscope and definite enough in form and structure to be classified with other known genera, do not grow at present from non-living matter. But it is not therefore certain that protoplasm or living matter may not be so formed in extremely small quantities, too small to be visible and of simple or no structure, but yet sufficiently complex in composition to serve as food for other and more highly developed animals. Whether this be so or not, Huxley and Spencer in their time and nearly all biologists since have been agreed in believing that in past time molecules of simple matter by some series of reactions became aggregated until a matter, sufficiently complex and sufficiently unstable to be called living matter, was formed, whilst there is no evidence that any such generation is taking place at present. When conditions on this planet became favourable, protoplasmic substance presumably came into being. The origin of protoplasm was in all probability the result of a combination of circumstances that never occurred before in the history of the earth, and which has never happened since.

History. It must always have been a matter of common experience that many articles of food are apt to become mouldy and to putrefy if kept too long. Associated with mould and with putrefaction are various sorts of low forms of life. The ancient philosophers never doubted that these were generated in the matters in which they made their appearance. Indeed, all men believed this until past the middle of the 17th century. But in 1660 in Italy, in those days the home of learning, Francesco Redi published his *Esperienza intorno alla Generazione degli Insetti*. He was no theorist, but a careful experimenter. Here, said he, is meat; if I expose it to the air in hot weather, in a few days it putrefies and swarms with maggots; but if I protect similar pieces of meat by covering them with fine gauze, then, though they still putrefy, not a maggot makes its appearance. From this experiment it becomes obvious that the maggots are not generated in the meat, but that the cause of their formation is something that is kept away by fine gauze. This something can be easily shown to be

blowflies, for these, attracted by the meat, swarm near it and lay their eggs on the protecting gauze, eggs from which maggots are shortly hatched. Now this is the principle of the whole matter; keep away all living things which might come to the meat and the meat will not create any living things, will not even putrefy if one kills any living animals or germs of animals that may be in the meat. The protecting gauze must be fine enough, that is all. Redi of course was accused of controverting Scripture, because of the story of the bees which were said to be generated in the carcass of the lion. But his doctrine of Biogenesis flourished for a century. Indeed when, through the development of the microscope, the numerous provisions for the production of germs were made known, the hypothesis of Abiogenesis, that life could come from what was not living, appeared absurd. Leeuwenhoek (q.v.), 1632-1723, is remarkable as being the first man to demonstrate existence of unicellular organisms. During the 18th century the microscope was greatly improved. The animalcules (infusoria) which in a few days will swarm in any infusion of organic matter became visible, and Needham, on theoretical grounds, doubted whether Redi's generalisation, 'no life without antecedent life,' held true for these lowly forms of life. He put his doubts to the test. He argued that if the infusorial animalcules came from germs, then the germs must exist either in the substance infused or in the water used to make the infusion or in the air that touches both of them. The life of all germs is destroyed by heat. If, therefore, the infusion be boiled, any germs present will be killed; and then if the infusion be shut off from the air no more germs can get into it. Now, if after this treatment animalcules still appear in the infusion they will have been generated from the infused substance or from the water; but if they do not appear, then Redi's dogma will be true for infusoria. He therefore boiled and corked infusions of various substances, and in every case after a longer or shorter time animalcules appeared and flourished. Needham was associated in much of his work with Buffon. The French naturalist had a theory of life to which Needham's experiments lent support. Life, he thought, was the indestructible property of certain molecules, which he described as 'organic molecules.' All living organisms, he said, are built up of such molecules; death is nothing more than their dissociation. When they are thus set free they take the form of infusorial animalcules. It is necessary to distinguish this theory, which is so ingenious, from the theory of Abiogenesis, the antithesis to that of Biogenesis, which supposes that life may and does arise from non-living matter.

But the theory of Buffon, and especially the experiments of Needham, which lent it support, did not seem satisfactory to Spallanzani. He saw two sources of error—first, the germs present in the infusion might have escaped death through not having been boiled long enough; and secondly, the corks, perhaps, were not perfectly effective, and air containing germs might have got into the flask and infected the infusion. So he too prepared infusions; but he boiled them for three-quarters of an hour, and then fused the necks of the flasks. He found after this treatment that the infusions remained perfectly free from living organisms for as long as he chose to keep them. It might seem that this must be the end of the whole matter; but the event proved otherwise. This time it was the chemists who reopened the discussion. Oxygen was discovered, the theory of respiration was begun, and it was proved that a supply of free oxygen is one of the conditions of life and also of putrefaction. So it

was possible that Spallanzani's infusions did not produce life either because the 'organic molecules' were altered in some way by being boiled, or because they were unable, owing to the absence of oxygen, to live. So the experiments had to be repeated in such a manner that the organic matter was not altered, and so that there was sufficient oxygen. Schulze and Schwann in 1836 took up the matter. They carefully boiled their infusions, and then supplied air; but they made it pass through red-hot tubes first, so that any germs present in it would be burned. In these conditions no animalcule appeared in the infusions; but if they were exposed to air which had not been heated then animalcules appeared in abundance. Therefore boiling does not injure the vitality of the 'organic molecules,' if there are such, and there is only one possible objection to the conclusions drawn from such experiments, if they be properly conducted, and that is that what the red-hot tubes destroy is not germs, but something else that may be non-living and yet essential to life. Now about this time Cagniard de la Tour discovered that fermentation, like putrefaction, is always accompanied by the presence of minute living creatures. Common yeast, for instance, is a mass of minute plants. When it was suggested that the living creatures not only accompanied but actually caused the processes of fermentation and putrefaction, the chemists, led by Liebig and Berzelius, laughed the idea to scorn. But in 1843 Helmholtz ingeniously separated a putrescent from a putrescible fluid by a membrane, so that the products of putrefaction could mix with the putrescible matter; but that did not in consequence putrefy. Therefore it followed that the cause of putrefaction must be either a colloid—indiffusible stuff—or a solid. In 1854-59 Schroeder and Dusch cleared up this point by experiments which were simply refinements upon the original ones of Redi; instead of using a screen of gauze to keep off blowflies they used a screen of cotton-wool, a screen with meshes so fine that not even the tiny germs can pass through them. They boiled infusions, and while the steam was coming off freely they plugged the neck of the flask with cotton-wool. Now this plug did not keep away oxygen, nor did it in any way heat or alter the air that passed to the fluid, as the red-hot tubes of Schulze and Schwann had done, and yet no animalcules appeared in the boiled infusion screened by cotton-wool. It is therefore proved that the cause of putrefaction and fermentation and the origin of the living forms that accompany these processes must be small particles that exist in the air.

But in 1859 Pouchet published his *Intérogénie*. He once more raised clouds of doubt. It seemed evident to him that spontaneous generation was one of the means that nature employed for the reproduction of living beings. If, he said, all putrefaction is the result of life present, as germs, in the air, then the air in which we live would have almost the density of iron! About this time Pasteur took the matter up, although advised by his friends, in view of the difficulty of the subject, not to do so; at least, said Dumas, do not spend too much time over it. But in 1862 he published a paper on *The Organised Particles existing in the Atmosphere*. He had collected the floating dust of the air and examined it with a microscope. He saw that much of it actually consisted of organised particles, and on his sowing these in suitable sterilised infusions they grew from them rich crops of animalcule. He also showed that these germs of life were not universally diffused in the air. He opened his sealed flasks in the pure air of the Mer de Glace. Only one out of twenty such flasks thus opened became filled with life; while eight out of twenty opened

in the air of the plains did so, and all of them did so if opened in the air of towns. These researches of Pasteur were necessary before Lister could have brought his system of antiseptic surgery to a successful issue; while he himself, as is well known, did great work upon the relations of these forms of life to many industries and diseases. The germs of the air were then studied by Cohn, shown by him to be bacteria, and the basis of a sound knowledge of them was laid. In 1869 Tyndall hit upon a very precise method of determining the absence or presence of dust particles in the air, a method much more searching than that furnished by the most powerful microscope. He was experimenting in another direction, and had need of air free from dust. He noticed that such matter (dust) passed easily through liquids. A beam of light shows the presence of dust particles in the air by the reflection that occurs from the surface of such. Tyndall showed that whenever dust was present the putrefaction occurred sooner or later, when it was absent it did not. Tyndall's apparatus was a box with glass sides, into the bottom of which the mouths of flasks penetrated, the lower parts being outside the box, so that the contained infusions could be boiled. A beam of sunlight was allowed to pass through the box; it showed the presence of dust in the air in a way with which every one is familiar. The inside of the box was then coated with glycerine, and the whole was kept as still as possible. After some time the dust particles sank to the floor of the box, and stuck to the glycerine, and a beam of sunlight passing through was quite invisible, there not being anything to reflect it. The infusions were then boiled for a long time, and then allowed to cool, after which they might be kept for months without putrefying or showing any signs of the presence of life. Here all the conditions of the infusions were natural, save that there was no dust in the air above them. In the dust of the air therefore are solid germs of life. The opponents of the doctrine of Biogenesis had long made objection to it, saying that 'if true then the air must be thick with germs; now this is absurd, therefore the doctrine is untrue.' An argument this that shows that a *reductio ad absurdum* is not always a proof.

See BACTERIA, BATHYBIUS, LIFE, PROTOPLASM, PUTREFACTION; and Haeckel's *Natural History of Creation*.

Spontini, GASPARO LUIGI PACIFICO (1774-1851), Italian composer, was born at Majolati in the March of Ancona, and studied at Naples. In Paris his one-act opera, *Milton*, attracted notice; and the grand opera *La Vestale* (1807) was greeted with enthusiastic acclaim, and was adjudged the prize of 10,000 francs instituted by Napoleon. An equally warm reception was accorded to *Ferdinand Cortez* in 1809. In the following year Spontini was appointed director of Italian opera at the Odéon. *Olympia* (1819) was less successful. In 1820 Frederick-William III. summoned him to Berlin. There he remained more than twenty years, though during the greater part of the time it was only court influence that supported him against the enmity of the Berlin public and of the Prussian press. Spontini was jealous of Weber, and was by nature quarrelsome and vain; but as a musician he entertained the loftiest aims, possessed true artistic taste, was grandiose in his conceptions, and breathed the spirit of genuine melody into his compositions. In Berlin he wrote three other grand operas—*Nourmahal* (1822), *Alcidor* (1825), and *Agnes von Hohenstaufen* (1829), his greatest work. Dismissed by Frederick-William IV. in 1842, he gradually withdrew into private life. See monograph by Robert (Berlin, 1883), and Grove's *Dictionary of Music*.

Spontoon. See PIKE.

Spoonbill, a family of birds, *Plataleidae*, allied to the *Ibidae*, and more distantly to the storks, and distinguished by the remarkable form of the bill, which is long, flat, broad throughout its whole length, and much dilated in a spoon-like form at the tip. The species are not numerous, but are widely distributed; the birds, are, however, becoming scarce owing to the drainage of their native haunts. The only European species is the White

Spoonbill (*Platalea leucorodia*).

Spoonbill (*P. leucorodia*), till the 17th century nesting in Britain, but now only a visitor. This bird was known as the Shovelard or Shovelar, while the duck now known as the Shoveler was then called the Spoonbill. In Northern Europe the Spoonbill is uncommon; it breeds in Holland, in the south of Spain, and the Black Sea district. Eastward in summer it ranges to India, Ceylon, and northern China; it is resident in North Africa. In South Africa it is represented by another species, *P. tenuirostris* or *cristata*. It is gregarious, but its nesting habits vary in different countries: in Holland the nests are made of reeds, and placed on the mud among rushes; in Slavonia on the submerged branches of willows; and in India on trees. It is about 32 inches long. Its colour is white, slightly tinged with pink; the bill and legs are black. A curious convolution of the windpipe, in the form of a figure 8, is found on dissection in the adult spoonbill, but does not exist in the young. The flesh of the spoonbill is said to be tender and of good flavour. The spoonbill is easily tamed, is quiet and inoffensive, and feeds readily on any scraps. The Roseate Spoonbill (*P. ajaja*) is an American species, and the only one; very abundant within the tropics, and found in the most southern parts of the United States. It is nearly equal in size to the White Spoonbill, which it resembles in its habits. It is a beautiful bird, with plumage of a fine rose-colour, deepest on the wings; the tail-coverts are crimson. *P. regia* or *melanorhynchus* and *P. flavipes* are found in Australia.

Sporades. See ARCHIPLAGO.

Sporadic (Gr. 'scattered') is a term applied to any disease that is commonly epidemic or contagious, when it attacks only a few persons in a district and does not spread in its ordinary manner.

Spore. This is a general name used for the asexual and sexual reproductive bodies produced by plants and animals, but applied more particularly to those of plants. The simple word spore is commonly qualified by some prefix indicative of origin, development, or behaviour. The older terminology given in ignorance of these principles was slowly modified as discovery

progressed; hence a considerable nomenclature of old and new terms has arisen to the perplexity of students. Individual spores are generally invisible to unaided vision, being commonly less than $\frac{1}{100}$ inch in longest diameter. Some, indeed, even 100 times smaller than that. Certain multicellular spores, however, like the macrospores of *Selaginella*, are visible to the unaided eye, and in former eras there were giants the size of a pea, or even of a hazel nut. Each unicellular spore consists of a particle of protoplasm, a nucleus and a supply of food substance, all enclosed within a protective covering which may be excessively thin or relatively very thick. This covering may be smooth or covered with warts, prickles, reticulations, or otherwise ornamented externally. The usual shape of spores is spherical or elliptical, others are attenuated, even needle like, while a few are irregular in outline. The majority are immotile, but many are endowed with locomotive power, swimming in water or even creeping on soil. Various methods of production and development may be found in articles mentioned below. In certain Algae and Fungi spores normally asexual may become sexual in an unusual environment, and the converse may occur. Because asexual spores and female spores when fertilised commonly reproduce the organism, they are often regarded as the seeds of cryptogams, an assumption due to misapprehension of form and function, and confusion of analogy with homology. The seeds by which all normal flowering plants are reproduced are not comparable with spores. A seed differs vastly from a spore in that it contains an embryo plant, although in a condition of latent life. A seed is the product of a fertilised female spore, the embryo from which suspends its activity at a certain stage; by which time it has been supplied with a store of nutriment for beginning future development; its spore-case, too (not spore-coat), having become modified into the protective seed-coat. One or more such seeds is contained in the ripened ovary, the whole, botanically speaking, forming the fruit. Among the lower plants and animals the spores are often cast into the surrounding element to live or perish. The higher organisms, however, provide their female spores with a protective chamber for early development, the spore then being variously termed oospore, egg or ovum, &c., and in due time the infant plant (the seed), or the baby animal is introduced to the arena of the world. The fertilised spore of a cryptogamic plant grows into a new being without an arrest of energy in the embryonic condition, consequently its embryo needs neither the store of nutriment nor the protective case of the seed. A survey of the existing and fossil plants and animals, from lowest to highest types, with regard to the gradual advance afforded for the protection of the female spore forms an exceedingly interesting study.

Many Thallophytes are reproduced, through perhaps several generations, by asexual spores which, in the various species, may arise in different ways receiving thus divers names. In most of the higher Thallophytes sexual spores are also produced either in regular or irregular succession with the asexual spores. The sex spores, again, receive a variety of names which emphasise some peculiarity. In many cases asexual spores produce plants which bear only sex spores, the female spore of which after fertilisation develops into a plant producing only asexual spores, the rhythm of alternating generations being thus maintained. In other cases, particularly in flowering plants and mammals, the fertilised female spore produces an organism which gives origin to sex spores again, so that alternating generations are, at least, not so evident.

In the body cells of plants and animals there exists a governing portion termed the nucleus. This organ consists chiefly of exceedingly minute, often rod-like, bodies called chromosomes which are supposed to be the chief vehicles of inheritance. Every plant and animal possesses its own specific number of chromosomes for its nuclei. Now as the sex cells are off-growths from certain body cells, one would suppose the former to contain the same number of chromosomes as the latter. Were this the case the number of chromosomes would be doubled at every generation that was the product of their union. To overcome this difficulty the chromosomes of the sex cells (the spores) are halved in number, so that in the fusion of male and female spores the normal body number is restored to the resulting embryo. One reason for difficulty in obtaining hybrids between certain different species of organisms is that they possess a difference in number or character of chromosomes. With the higher plants and animals the necessary reduction of chromosomes usually occurs during the production of the sex spores themselves, but this is by no means the general law among the lower plants and animals, for with them the reduction may occur at a period in the life-cycle of the organism entirely remote from the formation of the sex spores, and even in a different individual. Thus among the ferns reduction occurs during the formation of the asexual spores, which are produced in spore-cases on the underside of the fern frond. These spores having half the number of chromosomes, compared with those in the body cells of the fern plant, give origin to prothalli whose body cells, having the reduced number, produce sex cells without further chromosome reduction.

In the red sea-weed *Polysiphonia fastigiata* there are male, female, and neuter individuals concerned in the life-cycle, all morphologically alike except that each bears a different kind of spore: in horse-tails also three individuals but all different morphologically, the neuter horse-tail plant and the male and female prothalli: in ferns but two individuals, the neuter fern plant and the bisexual prothallus: in flowering plants only one individual, as the two sex individuals have become reduced to microscopic proportions and exist as parasites upon the neuter, which is the ordinary plant. This ascent of the neuter generation to the position of dominant partner in the life-cycle of organisms has been partly in response to the stimulus of hunger, and partly to the stimulus of providing more effectually for its offspring.

See BACTERIA, ALGAE, FUNGI, MOSSES, LIVERWORTS, FERNS, FLOWER, OVULE.

Sporophyte, the spore-bearing or asexual generation in plants, that is, in flowering plants and ferns what we recognise as the plant itself; while in Bryophytes the gametophyte is the 'plant,' the sporophyte growing upon it. See GENERATIONS (ALTERNATION OF), MOSSES, LIVERWORTS, FERNS, &c.

Sporozoa, a class of parasitic Protozoa, more or less equivalent to the Gregarinida (q.v.), including many very important forms, such as those which cause malaria and silk-worm disease. See Minchin, in Lankester's *Treatise on Zoology*, Part I. (1903); Doflein, *Protozoen als Parasiten und Krankheitserreger* (1901); Brumpt, *Parasitologie* (1910).

Sports. See ATHLETIC SPORTS, CRICKET, CURLING, CYCLING, FOOTBALL, FOX-HUNTING, GOLF, ROWING, TENNIS, &c.

Sports, BOOK OF, was the name popularly given to James I.'s Declaration in 1618, that on Sundays, after divine service, 'no lawful recreation should be

barred to his good people, which should not tend to the breach of the laws of his kingdom and the canons of his church'; some Puritan authorities in Lancashire having caused much discontent (and strengthened the Roman Catholic cause) by illegally suppressing the customary recreations of the common people. The sports specified were dancing, archery, leaping, vaulting, May-games, Whitsun-ales, morris-dances, and the setting up of May-poles. Among the excepted unlawful sports were bear-baiting, bull-baiting, bowling, and interludes. Persons not attending church were prohibited from joining in the sports, nor was any one allowed to go out of his own parish for that purpose, or to carry offensive weapons. By republishing this Declaration in 1633, and enforcing with great severity the reading of it by the clergy in their churches, Charles I. and Laud excited among the Puritans a degree of indignation which contributed not a little to the downfall of the monarchy and the church. In 1644 the Long Parliament ordered all copies to be publicly burned. See L. A. Govett, *The King's Book of Sports* (1890).

Spotted Fever. See MENINGITIS.

Spottiswoode, JOHN, Archbishop of St Andrews, son of John Spottiswoode, Superintendent of Lothian, was born in 1555. He was educated at the university of Glasgow, and at eighteen succeeded his father as parson of Calder. In 1601 he attended the Duke of Lennox as chaplain on his embassy to France, and in 1603 King James to London. Soon after he succeeded James Beaton as Archbishop of Glasgow, but was only consecrated in London in 1610. As Moderator of the General Assembly at Glasgow in 1610 he laboured to confirm episcopal government, and he forced the Perth Assembly (1618) to sanction the five points of discipline known as the Perth (q.v.) Articles. He was translated to the see of St Andrews in 1615. He officiated at the coronation of Charles I. at Holyrood in 1633, and in 1635 became Chancellor of Scotland. He reluctantly entered into the king's unwise measures for the introduction of a liturgy into Scotland, and naturally became hateful to the Covenanters. The king compelled him to resign the chancellorship in 1638, and that same year the Glasgow General Assembly deposed and excommunicated him. Spottiswoode died at London, 26th November 1639, and was buried in Westminster. His chief work is the well-known *History of the Church of Scotland* (1655; 3 vols., ed., with a Life, by Bishop Russell for the Spottiswoode Society, 1849-51).

Spottiswoode, WILLIAM (1825-83), mathematician, born in London, was educated at Harrow and Balliol College, Oxford. He took a first-class in mathematics in 1845, and later both the junior and senior university mathematical scholarships. For some time he lectured at Balliol, and in 1846 he succeeded his father as the head of the great printing-house of Eyre and Spottiswoode. Although throughout life an energetic man of business, he found time for much original work in abstract mathematics and experimental physics; as well as for travels in Eastern Russia (1856), Croatia and Hungary (1860), and for a large hospitality at his houses both in London and at Sevenoaks.

Spottsylvania Courthouse, a small village of Virginia, 55 miles N. by W. of Richmond, the scene of one of the most desperate and sanguinary battles of the civil war. On 10th May 1864, during the Wilderness campaign, Grant attacked Lee in his earthworks, and was repulsed with dreadful slaughter; yet on the next day he wrote to the secretary of war, 'I propose to fight it out

on this line, if it takes all summer,' and on the 12th repeated the assault, when Hancock's corps carried and held the 'bloody angle' (see HANCOCK). The next morning Lee, unable to bear his share of the heavy losses, withdrew within an inner line of entrenchments, and on the 20th Grant, having failed to dislodge him, moved round his flank towards Richmond.

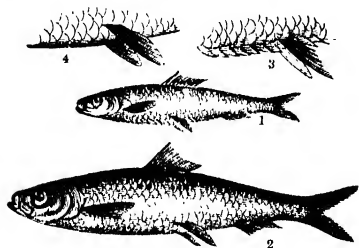

Sprain, or **STRAIN**, is a term employed in Surgery to designate a violent stretching of tendons or ligamentous parts with or without rupture of some of their fibres. Sprains are very frequent in all the joints of the upper limbs, especially in the wrist and the articulations of the thumb. In the lower extremity the ankle is the joint by far the most frequently affected; and this is accounted for anatomically by the small size of the articular surfaces, the great weight the astragalus (the bone presenting the lower articular surface) has to support, and the unyielding nature of the leg bones. In slight sprains of this joint the ligaments are only stretched or slightly lacerated, but in more severe cases they may be completely torn through. Sprains of the ankle are sometimes mistaken for fractures, and *vice versa*; and the two injuries may co-exist. The pain and swelling sometimes make an accurate diagnosis difficult, especially if the patient is not seen for some time after the accident; and if any doubt exists the case should be subjected to X-ray examination, which shows the presence of any fracture or crack in the bone, and indicates the necessity for more thorough treatment; the treatment proper for a fracture will also suit a sprain well, and a severe tearing of ligaments is sometimes as disabling as a fracture of the bone. Sprains of the knee are not uncommon, and are characterised by great swelling from effusion of fluid within the joint. Sprains of the back are not unfrequent accidents, e.g. among miners, and are the most serious of any, but in most cases it may be anticipated that after confinement in bed for two or three weeks, and with proper treatment, the patient will be able to walk, although he may feel stiffness and pain for several weeks longer.

The best treatment of a sprain depends chiefly upon the time that has elapsed since the injury. If the patient is seen before swelling has occurred the application of cold by means of ice-bags or running water, especially if a thin india-rubber bandage is previously applied, does much to control the swelling and the pain. At a later stage, if the pain be severe, warm applications (hot water, hot fomentations, or poultices) are generally very soothing; or lead and opium lotion may be employed. Where the swelling is very great a light elastic bandage gives relief. When the pain is not very intense the joint may be enveloped in a large quantity of cotton-wool, and gently but very firmly bandaged. It is important not to keep the injured joint too long at rest. As soon as the pain has subsided *massage* and gentle movements should be commenced; the patient should not be allowed to use the limb himself till these can be quite freely borne. In sprains of the back rest is the main requisite; and a belladonna plaster is both soothing and affords support; a supporting jacket may have to be worn for some time in severe cases.

Amongst horses sprains or strains are very common, owing to the severe exertions required of them, often whilst they are young, and unprepared for such work. Various muscles, ligaments, and tendons are liable to strain, but none more frequently than the large tendons passing down the back of the legs. In slight cases cold water continuously applied for several hours gives relief; but in all serious cases diligent fomentation with water about the temperature of 100° F. is preferable;

or the injured part may be swathed in a thick woollen rug, kept constantly moist and warm by frequent wetting with the hot water. Perfect rest is essential, and in order to ensure the relaxation of the large tendons of the horse's limbs he may in bad cases be put in slings for several days. Blisters, hot oils, firing, and all such irritants are on no account to be used until the inflammation abates and the part becomes cool and free from tenderness. Such remedies are then useful for causing the reabsorption of swelling, and perhaps also for invigorating the weakened part.

Sprat (*Clupea sprattus*), a fish of the family Clupeidae, very abundant on many parts of the British coast, and elsewhere in the northern parts of the Atlantic. It is smaller than the herring, being only about five inches in length when full grown, but much resembles it. It is, however, easily distinguished by the serrated belly, and by the position of the fins, the ventral fins beginning immediately beneath the first ray of the dorsal fin, and not beneath the middle of it, as in the herring

Sprat and Herring :

1, sprat; 2, herring; 3, belly of sprat; 4, belly of herring.

and pilchard. Another easily observed distinction is the want of axillary scales to the ventral fins, which both the herring and pilchard have. The dentition is also different, and on this account Valenciennes constituted for the sprat and a number of other species the new genus *Harengula*, characterised by having teeth on the jaws, tongue, palatines, and pterygoids, but no teeth on the vomer. The herring has teeth on the vomer. The sprat has only forty-seven to forty-nine vertebrae, whilst the herring has fifty-six to fifty-eight. The eggs are pelagic, like those of the pilchard. Perfectly ripe sprats are only found in the sea, to which they repair for the purpose of spawning, not, however, wandering very far from land. At Plymouth they spawn from December to May, on the east coast of Scotland in May or June. The young are found, with young herrings, in estuaries, and are taken in large numbers to be consumed as Whitebait (q.v.). Sprats abound especially on the coasts of Norfolk, Suffolk, Essex, and Kent in November and several following months. Drift-nets are used for the capture of sprats off the coast of Kent, but the usual instrument for the purpose is the stow-net worked from a moored boat in estuaries and tide-ways. The stow-net is a large bag-net suspended between two horizontal beams beneath the boat, and about a fathom from the bottom of the water; ropes from the ends of the upper beam enabling the fisherman in the boat to keep the mouth of the bag always open and against the tide. Vast quantities are taken in this way, to be used as manure, and to supply London. The Firth of Forth produces sprats—in Scotland called *garvies*—in great abundance. But there are many parts of the British coast where the sprat is rare, some of these being parts

where the herring is plentiful. Notwithstanding its cheapness the sprat is a very fine fish, of flavour quite equal to the herring, although decidedly different. Dried sprats are a very common article of provision, and sprats are also sometimes salted. The *kilkie*s brought from Riga and other ports on the Baltic are sprats cured with spices, as also are the 'Norwegian Anchovies' sent in small wooden barrels from Norway to England. The value of the sprat does not seem to be as yet fully appreciated in Britain. Very closely allied to the sprat is another fish (*Clupea latula*), the *Blanquette* of the French, which is caught in great abundance on some parts of the west coast of France. Other allied species are found in other seas. One of them (*C. humeralis*), which abounds in the West Indies, and southwards as far as Rio de Janeiro, is much esteemed, but becomes poisonous at certain seasons, from some unknown cause. The question of species is very difficult, but there is no doubt that many a sprat is sold as a Sardine (q.v.).

Spree, a river of Prussia, rises in the east of Saxony, on the borders of Bohemia, and after a winding course of 227 miles, but bearing generally north and north-west, falls into the Havel (q.v.) at Spandau. Area of drainage basin, 3655 sq. m. The principal towns on its banks are Bantzen, Kottbus, and Berlin. In the Spreewald, a district near Kottbus much cut up by the interlacing arms of the river, there still exists a colony of Wends.

Sprengel, CHRISTIAN CONRAD (1750-1816), botanist, for some time rector at Spandau. His enthusiasm for botany led to neglect of clerical duties, and he was removed from his post. Though 'an observer of genius' and a generaliser ahead of his time, he won no recognition from his contemporaries, and lived in straitened circumstances in Berlin, giving lessons in languages and botany and leading excursions on Sundays. He discerned, as Sachs says, that 'all the peculiar characters of a flower can only be understood from their relations to the insects that visit them and effect their pollination'; he detected 'dichogamy' or the fact that the stamens and pistil of flowers are often mature at different times; he saw that 'nature appears not to have intended that any flower should be fertilised by its own pollen.' Though he did not discover the object of the crossing which he recognised to be a fact, he laid some of the foundations on which Darwin built. His book—one of the botanical classics—which did not make him famous until Darwin recognised its merits, was entitled *Das neu-entdeckte Geheimniss der Natur in Bau und Befruchtung der Blumen*, and was published in 1793. See Sachs, *History of Botany* (1890, from the German, 1875).

Sprengel, KURT, physician and botanist, was born at Boldekow in Pomerania on 3d August 1766, and died at Halle on 15th March 1833. All his life was spent in quiet labour at Halle, from 1789 as professor of Medicine and from 1797 as professor of Botany. He won a reputation as a writer on the history of medicine and as a student of the anatomical structure and functions of plants. His principal books are *Pragmatische Geschichte der Arzneikunde* (5 vols. 1792-1803), *Geschichte der Botanik* (2 vols. 1817-18), and *Neue Entdeckungen im ganzen Umfang der Pflanzenkunde* (3 vols. 1819-22). Rosenbaum edited in 1844 Sprengel's *Opuscula Academica*, with a biography.

Sprenger, ALOYS, orientalist, was born 3d September 1813 at Nassereit in the Tyrol, studied medicine, the natural sciences, and the oriental languages at Vienna, next at London assisted Count Münster, and in 1843 sailed to Calcutta. He was teacher, interpreter, librarian, and translator in turn, until in 1857 he became professor

be its temperature. Local conditions may affect the thermal state of springs, as in the case of the geysers in the active volcanic district in Iceland, and the warm springs near Naples; but where no such local influences exist the depth of the bed from which the water comes may be to some extent estimated by its temperature. Thermal springs occur in Britain at Matlock (66° F.) and Buxton (82°) in Derbyshire, at Bath (117°) in Somerset, and at Clifton (76°) in Gloucestershire. When water is brought to the surface from deep-lying strata, the temperature is found to increase in proportion to the depth of the bore (see ARTESIAN WELLS). The Wiesbaden springs have a temperature of 156°; others are actually at boiling-point. Remarkable thermal springs are those of New Zealand, and the geysers of Iceland and the Yellowstone (q.v.) Park. The presence of radium has been certified in the water of many springs.

Intermittent springs are sometimes produced by the ebb and flow of the tide, as at Richmond, where the rise at high-water is seen in the wells which flow from the arenaceous strata on the banks of the Thames; and sometimes they depend on the supply of rain-water. But there is a kind of spring the intermittences of which are believed to be owing to the structure of the internal cavities from which the supply is obtained. This will be more easily understood by a reference to the accompanying diagram (fig. 2). The large reservoir, A, is fed by the rain percolating through the rock. It communicates with the surface by a siphon-shaped tube, BCD. As long as the water in the reservoir

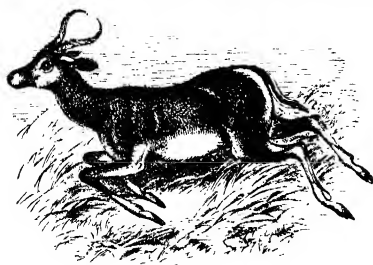

Fig. 2.

is at a lower level than the arch of the siphon at C no water can escape; but as soon as it reaches its level the whole of the water in the cavity will be drawn off, the spring will then cease, and will only make its appearance when sufficient water has accumulated to permit the siphon again to act.

Spring-balance. See BALANCE.

Springbok (*Antidorcas euchores*), an antelope, which like many others is getting scarcer; it is still,

Springbok (*Antidorcas euchores*).

however, abundant a little south of the Zambezi. It is an extremely beautiful creature, of graceful

form, and fine colours. It is larger than the roebuck, and its neck and limbs much longer and more delicate. The general colour is fulvous brown on the upper parts, pure white beneath, the colours separated on the flanks by a broad band of deep vinous red. The whole head is white, except a broad brown band on each side from the eye to the mouth, and a brown spot in the centre of the face. There is a peculiar erectile white fan of long hairs on the middle of the back, exposed when the animal runs. The springbok derives its name from the prodigious leaps which it takes either when alarmed or in play, often to the height of 7 feet, and sometimes more. Its ordinary haunts are in the *karruos* or arid sandy plains; but when all pasture there is burned up great herds congregate, and migrate to more fertile regions, often devastating the fields of the colonist. When taken young the springbok is easily tamed, and becomes very familiar, troublesome, and tricky.

Springer. See SPANIEL.

Springfield, (1) the capital of Illinois, stands in a fertile prairie country rich in bituminous coal, 185 miles by rail SW. of Chicago, at the meeting-point of seven railway lines. It is regularly laid out with broad streets and gardens, possesses a handsome federal building, a state arsenal, colleges, and one of the largest state capitols in the Union (of marble, 385 feet long by 296 wide). Its coal-mines have made it an active industrial centre: here are large factories for stoves, boilers, watches, shoes, and flour, and much else. Springfield, which became the capital in 1837, was the home of Abraham Lincoln, who is buried in the beautiful Oak Ridge cemetery, in the crypt of the great national monument—a granite obelisk (1874). Pop. (1880) 19,746; (1920) 59,183.—(2) A thriving city of Massachusetts, capital of Hampden county, on the left bank of the Connecticut River, by rail 99 miles W. by S. of Boston and 25 N. of Hartford. The river is crossed by five bridges to West Springfield (pop. 13,000), and four railways meet here. The city is stretching out over an elevated plain to the east; the older streets are broad, shaded avenues, and there is a large and beautiful park. The public buildings include a cathedral and numerous other churches, a brown-stone post-office, city hall, granite court-house, and a notable railway station. Springfield is remarkable for the great variety of its manufactures. Among its larger factories is the United States Armoury (since 1794), employing about 1000 men; the others embrace foundries, railway and motor car-works, and manufactories of cottons and woollens, paper, machinery, pistols, and many varieties of metal goods. The town was settled in 1635. Pop. (1880) 33,340; (1920) 129,614.—(3) Capital of Greene county, Missouri, 232 miles by rail WSW. of St. Louis, with machine-shops, car-works, and many other factories. Here is Drury College (Congregational; 1873). Near Springfield was fought the battle of Wilson's Creek, 10th August 1861. Pop. (1880) 6522; (1920) 39,631.—(4) Capital of Clark county, Ohio, on Lagonda Creek and Mad River, 80 miles by rail NE. of Cincinnati. Six railways meet here. The city contains the Wittenberg College (Lutheran; 1845), and handsome county and municipal buildings. Its principal products are various kinds of machinery (steam-engines, motor-cars, farm implements, &c.). Pop. (1880) 20,730; (1920) 60,840.

Spring-gun, a gun having wires connected with its trigger, and so fixed and planted that when wild animals, trespassers, &c., stumble against the wire the gun shall be discharged at them so as to wound them. Since 1827 it is illegal in Britain to set Man-traps (q.v.) or spring-guns save indoors as a defence against burglars.

Spring-tails (*Collembola*), an order of primitive wingless insects which, along with the somewhat similar *Thysanura*, are included in the small group Apterygota. The popular name refers to a peculiar springing fork which is usually present on the abdomen. It seems to result from a pair of abdominal appendages which are united at the base and bent forward when the animal is at rest. 'By a process analogous to that by which the common toy frogs are made to jump,' the spring-tails leap to a considerable height. The *Collembola* are all small, usually under a quarter of an inch in length; there are six or fewer abdominal segments; there are no compound eyes, nor hints of wings, nor metamorphosis. They usually live in damp and sheltered places—e.g. under bark or stones. Among the representative forms may be noted *Podura aquatica*, common on stagnant water in England; *Orchesella cincta*, among dead leaves and moss; *Desoria glacialis*, on the glaciers; *Sminthurus*; *Isotoma*; *Macrotona*. See Sir John Lubbock, *Monograph of the Collembola and Thysanura* (Ray Society, 1873).

Spruce. See FIR.

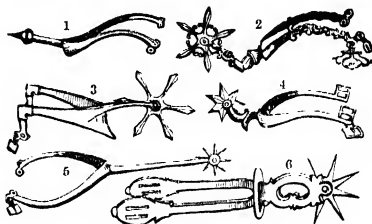

Spruce-beer. The essence of spruce is obtained by boiling the green tops of the Black Spruce (*Picea nigra*) in water, and then concentrating the decoction by another boiling without the spruce tops. The young shoots of this fir, like most others of its family, are coated with a resinous exudation, which is dissolved in the water. Spruce-beer was made by adding the essence of spruce to water in which sugar or treacle has been dissolved, in the proportion of about four ounces of essence of spruce to ten pounds of sugar, or three quarts of treacle, and ten or eleven gallons of water, with about half a pint of yeast. Various spices are used for flavouring. A similar beverage was made largely in the north of Europe, from the buds of the Norway Spruce (*Picea caesia*), and was known as Black Beer, that of Danzig being the most famous.

Spruce, RICHARD, botanist, was born the son of a schoolmaster on 10th September 1817 at Ganthorpe, in the North Riding of Yorkshire, and educated by his father. In his boyhood he showed a strong inclination towards plant collection, and, except for some five years spent in teaching mathematics at the collegiate school in York, his whole life was subsequently devoted to botanical research and collecting. He concerned himself especially with the study of mosses and liverworts, publishing, among other things, papers on their distribution in Eskdale, Teesdale, and Yorkshire. Ill-health sent him in 1845 to the Pyrenees, where he spent a year collecting the specimens described in the *Musci and Hepaticae of the Pyrenees* (Trans. Bot. Soc. Edinburgh, 1850). In 1849 he left on an expedition to South America, and for fifteen years he botanised in the Amazon basin, sending his specimens home periodically to George Bentham (q.v.), who acted as his agent in England. The species collected by Spruce during these years amounted to over 7000 in number. Of his numerous writings describing his work in South America the most important are *Palme Amazonice* (Linn. Soc. Journ. Bot., 1870) and *Hepaticae Amazonice et Andine* (Trans. Bot. Soc. Edinburgh, 1885), while his discoveries of South American mosses are included in the work on that subject published by William Mitten in 1867. After his return in 1864 Spruce retired to a small house in Coneythorpe, Yorkshire. He soon became a close invalid, and could only work under great difficulties. Completely bedridden in the end, he died 28th December 1893. Russel Wallace condensed and edited his *Notes of a*

Botanist on the Amazon and Andes, with a biographical introduction (2 vols. 1908.).

Spruner von Mertz, KARL, author of some useful historical atlases, was born at Stuttgart on 15th November 1803, joined the army of Bavaria, and taught geography in the Bavarian cadet college from 1855. His name is associated with a well-executed, and painstaking and accurate, *Historisch-geographischer Handatlas*, in three parts (1853-64), embracing in all 139 maps; besides this he published historical atlases of Bavaria (1838), Austria (1860), and Germany (1866), and a few historical works dealing with Bavaria. He received the rank of General-lieutenant in 1869, and retired in 1886. He died at Munich, 24th August 1892.

Spur, an apparatus fastened to the heel of a horseman, for goading the horse. It is much less

Various Kinds of Spurs

(From Antiquarian Museum, Edinburgh):

1, bronze puck spur found at Linlithgow Palace; 2, iron spur found near Hamockburn; 3, bronze spur found at Colchester; 4, brass spur found at Chuloden; 5, spur found at Haldon Hill; 6, spur found in making a drain in High Street, Edinburgh.

used than formerly, and the modern apparatus, having only minute serrations on its rim, does not possess the cruel effect of the formidable spiked spurs of old times here illustrated. All cavalry soldiers wear spurs, but their use, except in the heat of an actual charge, is discouraged as much as possible. In the age of chivalry spurs were an essential ensign of knighthood, the spurs of knights (*equites aurati*) being golden or gilt, while those of squires were of silver. In the degradation of a knight—a ceremony now rarely performed—one part of the proceedings consisted in hacking the spurs from his heels. Till into the 19th century knights of the shire might enter the House of Commons wearing spurs.

Spurge (*Euphorbia*), a genus of plants of the family Euphorbiaceae, having a very peculiar inflorescence described at CYATHUM. The fruit has three valves and three cells, the cells one-seeded, and bursting elastically. The species are very numerous, natives of warm and temperate climates, mostly herbaceous, but some of them woody. About twelve species are natives of Britain. All contain a resinous milky juice, which in most is very acrid. Several tropical species are cultivated for their great beauty in hothouses. No other genus in the whole vegetable kingdom shows such extreme diversity of form. Some, like *E. humifusa* and *E. maculata*, insignificant tiny weeds, may be seen between the paving-stones of Lugano, Como, and cities further south, accidentally introduced there from America. *E. nutans*, about 2 span high, from America too, covers the St Gotthard Line. *E. dendroidea* is plentiful on the coast from Nice to Naples, and forms there bushes from 3 to 10 feet high. *E. abyssinica* presents itself in the shape of huge leafless columns, like a cactus; and so do *E. Dinteri* and

E. resinifera in South and North Africa respectively. *E. meloformis* is like a melon; *E. candelabrum*, a mighty candelabrum; *E. Caput-Medusæ*, a turnip just peeping out of the ground, from which run long branches of the thickness of a rope, twisting themselves on the ground like snakes; and this resemblance explains the name of a somewhat smaller plant growing in South Africa too, which is called *E. viperina*.

Spurge Laurel. See DAPHNE.

Spurgeon, CHARLES HADDON, preacher, the son of an Independent minister, was born at Kelvedon, Essex, 19th June 1834. He was educated at Colchester and Maidstone, and in 1849 became usher in a school at Newmarket, where he studied French and Greek, spent his leisure time in religious work, and began to give addresses in the hall of the Independent chapel. In 1850 he removed to Cambridge, connected himself with the Baptist church there, and was received as a member of the Lay Preachers' Association. In his eighteenth year he had a call to be pastor of the Baptist chapel, Waterbeach, and soon the small congregation was doubled. In 1853 he was invited to preach in New Park Street Chapel, London, and in 1854 he was unanimously called to become its pastor. Growing popularity made enlargement of the chapel a necessity in 1855 and 1856, services being conducted first in Exeter Hall, and then in the Surrey Music Hall in the interim. A panic occurred (19th October 1856) while Spurgeon was preaching in the latter place, and when 7000 persons were assembled; seven persons lost their lives, and many were injured. At a service in the Crystal Palace, on a day of national humiliation in connection with the Indian Mutiny, Spurgeon preached to an audience of about 24,000. The vast Metropolitan Tabernacle was erected in 1859-61; it was burnt down in 1898. Strangers flocked thither from all parts of the world to hear the popular preacher. In 1879 he received a pastor's silver-wedding testimonial of over £6000; a further sum of about £5000 was presented to him on his attaining his fiftieth year, all of which he devoted to benevolent schemes. In 1887 he withdrew from the Baptist Union, because no action was taken by its leaders against persons charged with fundamental errors, whom he thought on the 'down-grade' theologically and spiritually. In his later years repeated illnesses led to his wintering in the south of France; he died at Mentone 31st January 1892. A musical voice, clearness, directness, independence, and simplicity of style, combined with humour, common sense, a rich store of anecdote and continuous hard work, contributed to his power. Around the Metropolitan Tabernacle grew up almshouses, the Pastor's College (1856), and the Stockwell Orphanage (1867).

Besides his weekly sermons and a monthly magazine, *Sword and Trowel* (1865), Spurgeon gave to the world upwards of a hundred volumes, mainly based on his sermons. He always preached extemporaneously, had his notes written on a half-sheet of note-paper, and the sermons, taken down in shorthand, were afterwards carefully revised by himself. The average weekly circulation of his sermons was 30,000; one reached 200,000. Some 3500 sermons have been published. Other books were the very popular *John Ploughman's Talk* (1868) and the *Treasury of David*, a commentary on the Psalms in 7 vols. (1865-80). The authorised life, largely autobiographical, was published by his wife and Mr Harrauld (1897-99). There is also a *Life* (1920) by Fullerton; and his letters were collected (1924) by his son.—Of his twin sons one, Thomas, born 1856, studied at the Pastor's College, and, after some years' service in New Zealand, accepted the pastorate of the Metropolitan Tabernacle in 1893. His health failing, he resigned this post in 1908 to become president of the Pastor's College and of the orphanage, and died 21st October 1917.

Spurn Head, a promontory stretching 2½ miles into the mouth of the Humber (q.v.), and forming the south-eastern extremity of Yorkshire. It is connected with the mainland by a causeway of pebbles and sand 300 yards wide, and, unlike so many headlands, rises only a few feet above sea-level. The spit seems largely to be composed of shingle and drift washed by the sea currents from the coast of Holderness to the northward, and seems to have come into existence only in the early part of the 16th century. Outside the Spurn is deep water; to the west the desolate Trinity Sands, and beyond them Sunk Island, an embanked tract of 6000 acres of rich farming land. Close by what is now the Spurn stood the old port of Ravenspur, which, like Hedon (close to Hull), was a notable place before Hull grew great. There Bolingbroke landed in 1399; but the sea was even then making ravages on the coast, and by the early part of the 16th century Ravenspur had almost completely disappeared. Since 1895 one lighthouse with a flashlight has superseded the two lighthouses (one of them by Smeaton) which used to mark the headland. See books on the lost towns by Boyle (1889) and Sheppard (1912).

Spurrey (*Spergula*), a genus of Caryophyllaceæ. The species are annuals, dichotomously branched; their leaves linear-filiform, with membranaceous stipules, in tufts owing to the growth of internodes being checked; the flowers in terminal cymes. The flowers have a calyx of five sepals, five white petals, five or ten stamens, and five styles; the capsule is five-valved, with numerous round seeds, surrounded with a membranous border. Common Spurrey, or Yarr (*S. arenaria*), is plentiful in cornfields, especially on light stony or sandy soils in Britain and most parts of Europe. In some parts of Europe a larger variety is frequently sown for fodder, and is much relished by cattle. Sand Spurrey is a kindred genus, *Spergularia*, mostly fleshy-leaved halophytes.—Knotted Spurrey is *Sagina nodosa*.

Spurs, BATTLE OF. See COURTRAI, GUINEGATE.

Spurzheim, JOHANN GASPAR, one of the founders of the so-called science of Phrenology (q.v.), was born near Trier on 31st December 1776. Whilst studying medicine at Vienna he became acquainted with Franz Joseph Gall (q.v.), and became a proselyte to his doctrines. The two in 1805 started on a lecturing tour through the principal countries of central Europe, and in 1807 they settled in Paris. In 1813 the two friends, their teachings disagreeing in some particulars, separated; Spurzheim proceeded (1814) to England, and lectured and wrote and laboured in the principal cities of the United Kingdom for four years, gaining a powerful adherent in George Combe (q.v.). After remaining at Paris from 1817 to 1825, Spurzheim again went back to England and renewed his propaganda, this time with much greater success. In 1832 he sailed to the United States, but died suddenly at Boston on 10th November that same year. Spurzheim advocated his doctrines with great eloquence and enthusiasm, and greatly popularised phrenology. He wrote on that subject and education. See Carmichael's *Memoir* of him (1833).

Spy, a place in the province of Namur in Belgium, where in 1886 were found in a cave, along with Mousterian flints, two skeletons which, in respect of brain-case, jaws, dentition, and other features, represented a very low type of humanity, the Neanderthal race. See ANTHROPOLOGY.

Spy, in WAR, is a useful but not highly honoured auxiliary employed to collect information and ascertain the enemy's intended operations. Spies are always used in war, and their employ-

ment is quite recognised by the law of nations as interpreted by Grotius, Vattel, and Martens; nor is it held to be any dishonour to a general to avail himself of their services. On the other hand, the spy himself is looked upon as an outlaw, and when taken is put to death ignominiously and without mercy. A spy is well paid, lest he betray his employer. In the British army spies are employed by the Intelligence branch under the quartermaster-general. In minor expeditions they are generally friendly natives. Military law, though distinct enough in ordering his death, is not clear in defining what constitutes a spy. A man, not belonging to the army, found within the lines, either in uniform or civil dress, if unable to give a good account of himself would certainly be arrested as a spy, and if anything suspicious could be proved against him would probably be hanged or shot; but if found in one camp in the uniform of the opposite side, he may not be treated otherwise than as a prisoner of war, or else as a deserter from the enemy.

Squadron. See CAVALRY, REGIMENT, TROOP.

Squarione, FRANCISCO (1394-1474), originally a tailor, but founder of the Paduan school of painters, best known as teacher of Mantegna (q.v.).

Square Root. See INVOLUTION.

Squares, METHOD OF LEAST, an arithmetical process of great importance, for combining observations, or sets of observations, so as to obtain the most probable value of a quantity which depends on these observations. It is in fact the scientific method of taking certain averages, and it finds its most constant use in astronomy and other physical sciences. The necessity for applying the method arises from the fact that, when the greatest precision of measurement is sought, repeated measurements of the same quantity do not agree. Thus, the altitude of a star at culmination, if carefully measured night after night by the same observer through the same instrument, will in general come out a little different in the different observations. All the measurements will, however, lie within a certain range of variation; and if all are equally trustworthy, the arithmetical mean will give the most probable value of the real altitude. The differences between this mean and the individual measurements on which it is founded are called the residuals. The important mathematical property of these residuals is that the sum of their squares is less than the sum of the squares of the differences between the individual measurements and *any* other single quantity that might be taken. Now, this principle of 'Least Squares' holds not only for the simple case just described, but also for more complicated cases in which one observed quantity (y) is to be expressed as an algebraic function of another or of several independently observed quantities (x). Here the object is to find the most probable values of the assumed constants or parameters which enter into the formula. When these values are calculated we can calculate in terms of them and the observed x 's a value of y corresponding to each set of observations. Comparing the calculated y 's with the observed y 's, we get a set of residuals, the sum of whose squares is a minimum if the parameters have been calculated according to a particular process. It is this process which is described as the method of least squares. Its basis is found in the mathematical principles of Probability (q.v.). See Professor Merriman's *Textbook on the Method of Least Squares* (8th ed. 1901), or Chauvenet's smaller treatise (1879), Constock's (1890), and for elementary discussion any good treatise on practical astronomy and geodesy.

Squaring the Circle. See QUADRATURE.

Squash, a term loosely used, especially in the United States, for two or three kinds of Gourd (q.v.), including the pumpkin.

Squid. See CALAMARY.

Squier, EPHRAIM GEORGE, American author and archaeologist, was born at Bethlehem, New York, 17th June 1821. From 1841 to 1848 he was a newspaper editor, latterly in Ohio; and his attention being attracted to the antiquities of the Scioto Valley, he made an exploration of similar monuments through the Mississippi Valley, an account of which was published in vol. i. of the *Smithsonian Contributions to Knowledge* (1848). He made similar explorations in New York in 1848; and next year being appointed *chargé d'affaires* to the states of Central America, he used his official position as a means of making extensive geographical and archaeological explorations in those regions. For his researches he received the gold medal of the French Geographical Society. In 1853 he surveyed a railway route through Honduras, and extended his archaeological inquiries. In 1863 he was appointed U.S. commissioner to Peru; and afterwards he edited Frank Leslie's publications. He died in Brooklyn, 17th April 1888. Among his works are *Neotiquia: its People, Scenery, and Ancient Monuments* (1852); *Serpent Symbols* (1852); *Notes on Central America* (1854); *Waukua, or Adventures on the Mosquito Shore* (1855); *Central America* (1857); and *Peru. Explorations in the Land of the Incas* (1877).

Squill (*Scilla*), a genus of bulbous rooted plants of the family Liliaceae, with radical leaves, and flowers in terminal racemes or loose corymbs. The species, which are numerous, are natives chiefly of the Mediterranean and Caucasian regions. Three

A, *Scilla verna*; B, Official Squill (*Urginea Scilla*): a, plant with flowering scape in blossom; b, plant with full-grown leaves. (From Bentley and Trimen.)

are natives of Britain, *S. verna*, which is abundant on the east coast of Ireland, the west and north coasts of Scotland, more sparingly on the east coast of Scotland, and very locally in north-eastern England; *S. autumnalis*, which is confined to some of the southern counties of England; and *S. festalis* (better known as *S. nutans*), otherwise *Endymion*

non-scriptum, the wood-hyacinth or blue-bell of England, which is very abundant in most parts of Great Britain and Ireland. These and many exotic species are frequently cultivated for the sake of their beauty in British gardens.

Very different in habit from these, and now separated from the genus, is the Official Squill (*Urginea Scilla*; formerly called *Scilla maritima*), a native of the sandy and rocky shores of the Mediterranean, which has a scape from two to four feet high, with a raceme of many whitish flowers and large leaves. The bulb is of the size of a man's fist, or sometimes as large as a child's head, and contains a viscid juice so acrid as to blister the fingers if much handled, whilst the vapour arising from it irritates the nose and eyes. Squill was used in medicine by the ancients, and is still largely employed. The bulb is dug up in autumn, divided into four parts, the centre being cut out as being inert, and the remainder being cut into thin slices, which are quickly dried by a gentle heat. The dried slices are white or yellowish white, slightly translucent, odourless, disagreeably bitter, brittle, and easily pulverisable if very dry. The bulb contains a number of active principles, the chief of which is a glucoside, *scillarin*, having much the same action as digitalis; other active ingredients have been described under the names *scillitorin*, *scillin*, and *scillipierin*. This medicine is prescribed as a diuretic and expectorant, and occasionally as an emetic; but it must be recollected that in moderately large doses it acts as a narcotico-irritant poison, twenty-four grains having proved fatal. When given as a diuretic it is usually prescribed in combination with digitalis and calomel, when it seldom fails to produce an increased secretion of urine, and thus promotes the absorption of the dropsical effusion which is generally present when diuretics are ordered. Its dose as a diuretic is from one to three grains of the powdered bulb, or about twenty minims of the tincture. As an expectorant it is much employed in the subacute stages and chronic forms of pulmonary affections, and is very serviceable in bronchitis and pneumonia of children. From its property of promoting the secretion of mucus, it gives relief by facilitating the expectoration in cases of asthma, &c., in which the sputa are viscid. In these cases it is usually prescribed with some of the more stimulating expectorants, as carbonate of ammonium. As an expectorant the dose of the powdered squill should not exceed one grain, repeated several times daily. For children the syrup, in doses of from ten to thirty minims, may be given. As its action as an emetic is uncertain and dangerous, it should not be prescribed with the view of inducing vomiting.

Squilla, a genus of Crustaceans, representative of the order Stomatopoda. The members are sometimes called *Mantis Crabs* or *Mantis Shrimps*, from the slight resemblance to the insects of the genus *Mantis* (q.v.). The body is slightly flattened; the carapace does not completely cover the thorax; the pincers of the large anterior forceps are formed by the last joint closing on the second last; the gills are borne by the first five pairs of abdominal appendages; the last pair of abdominal appendages form a broad tail fin. The species are numerous, especially in tropical seas. They are active, voracious crustaceans, fond of burrowing in the mud; they are often very brightly coloured; the young forms undergo a marked metamorphosis, which has not been completely followed.

Squint, or HAGIOSCOPE, a narrow aperture cut in the wall of a church (generally about two feet wide), to enable persons standing in the side-chapels, &c., to see the elevation of the Host at the high altar.

Squinting (technically, *Strabismus*) is a well-known and common deformity, which may be defined as a want of parallelism in the visual axes, when the patient endeavours to direct both eyes to an object at the same time. It may be due to loss of power (paralysis or paresis) of one or more of the eye muscles; and this may depend on a merely local affection, or may be a symptom of serious brain disease. But in the majority of instances, and in all ordinary cases of squint (to which this article will be confined), no such condition is present. The squint is said to be *convergent* when the squinting eye is directed towards the nose, and *divergent* when it is directed towards the temple; the convergent is much the more common. Misdirection of one eye upwards or downwards is of rare occurrence. If sometimes one eye and sometimes the other is misdirected, the squint is said to be *alternating*: if always the same eye, *monocular*.

Convergent squint usually comes on during childhood, most often from the second to the seventh year. If present at birth it is caused by some serious defect in the muscles. It is sometimes due to defective sight in the squinting eye, from congenital abnormality, severe inflammation, or injury; but very often no such condition is present. In a large proportion of cases it is accompanied by *hypermetropia* (see EYE), and is due to the increased effort of accommodation required to see near objects, being associated with an increased and disproportionate effort of convergence. In such cases, if suitable glasses can be worn as soon as the squint begins to show itself, it may be prevented from becoming permanent. It is but seldom, however, that the surgeon is consulted at a sufficiently early stage for this treatment to have a fair chance to succeed, and even at an early stage it is by no means certain to prevent the development of a squint. In other cases the presence of a squint may be traced to the presence of worms, the irritation of teething, &c.; and it disappears when the cause is removed. In early childhood, when one eye is less useful than the other, the child may gradually acquire the habit of using only the better eye. The power of vision in the less efficient eye then gradually deteriorates through disuse, unless the squint, refractive error, &c., are corrected at an early stage by suitable glasses, so that the child is forced to use both eyes.

Divergent squint is very rarely present without considerable defect in the sight of the squinting eye, except where it is the result of over-correction of a convergent squint by operation. It is often associated with myopia, as the other form is with hypermetropia. When the vision of one eye is damaged by disease or injury in the adult, and takes a faulty position in consequence, divergence is much more common than convergence; in children, as has been said, the latter is the usual result.

The surgical operation for the correction of a squint consists in the division of the muscle whose excessive activity leads to the faulty position—in convergent strabismus the internal rectus, in divergent the external. It is often necessary to operate on both eyes in the same manner, even where the squint is monocular. In some cases it is requisite in addition to shorten the opposing muscle (i.e. in divergent strabismus, where this procedure is most often resorted to, the internal rectus).

Squire. JOHN COLLINGS, English poet and critic, was born 2nd April 1884 at Plymouth, and educated at Blundell's School, Tiverton, and St John's College, Cambridge, where he graduated B.A. in 1906. He worked for a time in the press gallery of the House of Commons, and, over the name of 'Solomon Eagle,' wrote reviews for the *New Statesman*, with which periodical he was

editorially connected from 1913 to 1918. In 1919 he founded the *London Mercury*, and became its editor. Of his writings, which include poems, parodies, essays, reviews, and some short stories, the chief are: *Poems and Handclaire Flowers* (1909), *Steps to Parnassus* (1913), *Tricks of the Trade* (1917), volumes of *Poems* (1918, 1922, 1926), *Books in General* (1918, 1920, 1921), *Collected Parodies* (1921), *Grub Street Nights* (1924), *The Comic Muse* (1925). He edited a collection of J. E. Flecker's poems in 1916.

Squirrel, the vernacular name of the *Sciurus vulgaris*, and in a wider sense of all members of the sub-family Sciurinae. These are characterised by their slender body, cylindrical hairy tail, and large prominent eyes; the ears are of variable size—often tufted; anterior limbs shorter than posterior, the former have four fingers and a rudimentary thumb, the latter five complete toes. Their habits are for the most part arboreal; some few excavate subterranean retreats. Their distribution is cosmopolitan, excluding the Australian region. There are seven recent genera and several fossil ones. (1) *Sciurus*, in addition to the characters of the family above mentioned, has the tail long and bushy, ears pointed—often tufted, the digits with long, curved, sharp claws, skull delicate, with long post-orbital processes, penultimate upper premolar, when present, minute. *S. vulgaris*, the common squirrel, measures 18 inches long (including the tail, which is 8 inches), and weighs about half a pound; its colour in summer is brownish red above, mixed with gray on the side of the head, white below from the chin; in winter

Common Squirrel (*Sciurus vulgaris*).

the brownish red above becomes mixed with grayish hairs, whilst in Siberia and northern Europe the whole animal becomes whitish gray without a trace of red; black varieties occasionally appear. It occurs at the present day all over the Palaearctic region, from Ireland to Japan and from North Italy to Lapland, whilst its remains occur as far back in the geological history as the Cromer Forest Bed. In Scotland it bade fair to become extinct towards the end of the 18th century, but a rapid recovery was made between 1800 and 1850. Its favourite dwellings are dry and shady woods, especially of beech and oak, whose nuts furnish it with a winter food-supply. It is always in motion, and in fine weather may be seen skipping from tree to tree as if in pure enjoyment; on the ground its pace is so rapid that a dog can scarcely catch it, but it is still more at home among the branches, where its sharp claws enable it to cling safely to the smoothest bark. When undisturbed it seems to be constantly on the lookout for food, which, if abundant, is stored up for future use. It eats berries, nuts, bark, and buds, and is a greedy and

successful plunderer of birds' nests. Thus it helps to check the multiplication of wood-pigeons, but it does great harm in forests by eating off the tips of the main shoots and by gnawing the bark. The squirrel will use a bird's nest for a temporary lodging, but the home is always constructed afresh, though the materials collected by others may be utilised. The nest is usually situated in the fork of a branch near the stem, and has a roof to keep out rain, a main entrance opening downwards, and a smaller accessory opening near the stem. The squirrel lies curled up when asleep. It is very sensitive to the weather. It swims freely on occasion. Pairing takes place in spring, when there are often savage fights between the males; four weeks later three or four, occasionally more, young ones are born, which remain blind for about nine days; for five days or so after the young leave the nest the whole family sports together among the trees, and then breaks up. The squirrel is not a hibernator, though it may doze in very hard weather. It has very few enemies. Young ones are easily tamed and make interesting pets. The long hairs are used for 'camel's hair' paint-brushes. The fur of the squirrel has some commercial value, and large numbers are trapped in Russia and Siberia. In the early years of the 20th century the American Grey Squirrel (*S. carolinensis*) was inconsiderately allowed to establish itself in various parts of England and Scotland—an introduction to be watched with foreboding. The genus includes between seventy and eighty other species, some of those from the Oriental region being very highly coloured; in one of them (*S. caniceps*) the back becomes of a bright orange colour during the breeding season, a rare phenomenon among mammals. (2) *Pteromys* includes the Tanager or Flying Squirrel (*P. pteristista*), the largest of the sub-family, being nearly as large as a cat; see FLYING ANIMALS. (3) *Rhithrosciurus* is a large squirrel from Borneo, with black and white striped sides and grooved incisor teeth. (4) *Tamias* is an American genus, though one species extends into Asia and even to eastern Europe. All the four species have check-pouches, and the back is ornamented with darker and lighter stripes; see CHIPMUNK. (5) *Xerus* includes the so-called 'Spiny Squirrels,' of which there are four species, all African; the fur is coarse, the claws straight, and the external ear small or absent. They inhabit the dry steppes, and dig holes in the roots of trees or among rocks. The Prairie Dog (q.v.) was sometimes called the 'Barking Squirrel.' See J. A. Harvie-Brown's *History of the Squirrel in Great Britain* (Edin. 1881).

Squitch. See COUCH-GRASS.

Srinagar, or KASHMIR, the capital of the native state of Kashmir in Northern India, stands in a lovely valley of the Himalayas (besung by Moore in his *Lalla Rookh*), on both sides of the Jehlam (Jhelum) at an elevation of 5276 feet. Its appearance and situation are described under KASHMIR. Pop. (1921) 141,735.

Srirangam. See SERINGHAM.

St. For places named after saints (St Albans, &c.), see at SAINT.

Staal. MARGUERITE JEANNE, BARONESS DE, usually distinguished from the greater Mue. de Staël-Holstein as Madame de Staël-Delaunay, was born at Paris, 30th May 1684, the daughter of a poor painter named Cordier, whose name she dropped for that of her mother, Delaunay. She had a sound education at the convent of Saint Louis at Ronen, and at twenty-seven was attached to the person of the imperious and intriguing Duchesse de Maine at the little court of Sceaux. Here she saw before her eyes all that comedy of life which she was later

to describe with such penetrating insight. Her position was at first a servile one, and she must often have been sorely tried by the temper of her mistress, but in herself remained not one whit of what she calls the 'caractère indécidable de femme de chambre,' and all her life was ruled in harmony with her own words, that it is only our own actions which can degrade us. Her devotion to the interests of the Duchesse brought her two years in the Bastille, where she had a love affair with the Chevalier de Menil. In 1735 she married the Baron de Staal, an officer of the Guard. She died at Paris, 16th June 1750. Her *Mémoires* (1755; ed. Lesclapart, 1878; trans. by Bathurst and by Bell) show intellect and observation, as well as remarkable mastery of subtle irony, and are written in a style clear, firm, and individual. 'Je ne me suis peinte qu'en buste,' she says, by which must not be understood that this lofty soul and admirable writer was ever consciously or unconsciously untrue. For indeed sincerity is her first characteristic, and throughout she reflects things like a mirror, without addition, omission, or distortion. 'Le vrai est comme il peut, et n'a de mérite que d'être ce qu'il est.' Her *Œuvres Complètes* appeared at Paris in 2 vols. in 1821. See the study by Fray (1863), and Sainte-Beuve, *Portraits Littéraires*, vol. iii.

Staaten Island. See STAATEN ISLAND.

Stabat Mater. a celebrated Latin hymn on the seven dolours of the Blessed Virgin, whose authorship has been assigned to Jacopone da Todi, a Minorite who flourished in the 13th century. It has been set to music by many composers of eminence—e.g. Palestrina, Pergolesi, Astorga, Haydn, and Rossini.

Stability. the name given to the property possessed by all material systems whose configuration remains permanent or never departs far from a permanent average type. There are two kinds—static and kinetic. Of static stability, or stable equilibrium, we have numerous examples of a simple character. A pendulum or any body hanging under the influence of gravity by a point which is not its centre of mass; a ball resting inside a basin; any object resting on supports in such a way that a vertical line through its centre of mass falls well within the polygon formed by joining the points of support—all these are familiar instances. If any displacement (within certain limits) is given to the body, it will, when released, tend to recover its original condition. In dynamic language the forces brought into play by the displacement resist it. If, however, the ball is placed on the top of a convex surface, or if a chair, for example, is tilted until the vertical line through its centre of mass falls outside the original area of its base, then the configuration is no longer stable. Both bodies will fall away from these positions until a new configuration of stable equilibrium is reached. In general, stability is proved by a system recovering its configuration after a slight displacement. Instability is demonstrated when any slight displacement is followed by a complete change of configuration, forces being brought into existence which assist the displacement. When a displacement brings into play no forces, so that the system tends neither to recover nor to fall away from its original configuration, the equilibrium is said to be neutral or labile. A uniform sphere resting on a plane is a simple example of this kind of equilibrium.

In kinetic stability, or stability of steady motion, a new factor comes into play. Neither a spinning-top nor a bicycle can rest upright unless it is in more or less rapid motion. The moon would fall into the earth, and the earth into the sun, if it were not for the orbital velocity sustaining each in

its path. The perturbations produced by the planets cause the earth to be constantly deviating from its mean orbit; yet in virtue of kinetic stability this deviation is never large, and takes place now in one direction, now in another. If no frictional effects existed in the solar system, all the planetary orbits would never vary beyond certain assignable limits.

Stachys, a genus of plants of the family Labiatae, containing a great number of species found in all parts of the world except Australia and New Zealand, having a ten-ribbed calyx, with five nearly equal teeth, the upper lip of the corolla entire, and the lower lip three-lobed. Several species are natives of Britain. *S. sylvestris* is very common in shady places, a coarse herbaceous plant, sometimes called *Hedge Nettle*, with stem two to three feet high, ovate heart-shaped leaves on long stalks, whorls of purple flowers, and unpleasant smell. *S. palustris* is another very common British species, growing in moist places, and sometimes proving a very troublesome weed in meadows. The plant was formerly used as a vulnerary, and has therefore the English name *Woundwort*. Several species are not unfrequently to be seen in flower-gardens. Common Betony or Wood Betony (*S. Betonica*, or *Betonica officinalis*), plentiful in woods and thickets in the southern parts of Britain, is a plant one or two feet high, with hairy stem, oblong heart-shaped leaves, whorls of purple or white flowers, and a fetid smell. It was formerly much used in medicine. The roots, in small doses, are emetic and aperient.

Stade, an ancient town of Hanover, near the mouth of the Schwinga, a tributary of the Elbe, 22 miles W. by N. of Hamburg. There are large brickworks. Pop. 11,000. The *Stade Dues* was a toll charged by the Hanoverian government on all merchandise carried up the Elbe to Hamburg. First formally recognised in 1691, they gradually increased till they brought a revenue of £40,000 a year. They were abolished in 1861, Hanover receiving £428,600 as compensation, of which Britain and Hamburg contributed each £155,555.

Stadtholder (Dutch, 'stead-holder,' literally *lieutenant* or *Statholder*), is not connected with the German word *Stadt*, 'city,' as the barbarous English form Stadtholder suggests. The title of Stadtholder (i.e. royal lieutenant or viceroy) of the provinces Holland, Zealand, and Utrecht was in defiance of the rights of these provinces conferred in 1540 on a foreigner, René, Prince of Orange, at whose death (1544) it passed to his cousin, William the Silent. In 1559 there were in the Low Countries eight other Stadtholders of provinces, or groups of provinces, besides the Prince of Orange; all were commanders-in-chief of their provinces, and all except Count Egmont were also supreme civil and criminal judges. In Brabant there was no Stadtholder other than the Regent. After the United Provinces had thrown off the yoke of Spain (see the section *History* in the article HOLLAND) this title, now grown dear, was retained (though a misnomer) for the head of the republic, and became hereditary in the House of Orange until superseded by the title of king.

Stadium, the course on and over which the foot-races were run in Greece. That of Olympia was oblong in shape, and 631 feet long. Seats were provided overlooking the course for more than 40,000 spectators. Besides foot-races, leaping, discus-throwing, wrestling, and other sports were celebrated on the same racetrack. The stadium at Athens, levelled and laid out by the orator Lycurgus in the first half of the 4th century B.C., was 600 feet long by 130 wide, and its seats could accommodate as many onlookers as those at Olympia.

The length of the Olympian stadium was adopted as the Greek standard measure of length or distance. Seven and a half stadia, or 4732 English feet, were reckoned as equivalent to a Roman mile, at least in the time of the empire.

Stadtholder. See STADTHOUDER.

Staël, MADAME DE, one of the most illustrious of Frenchwomen, was born at Paris, 22d April 1766. Her full name was Anne-Louise-Germaine Necker, and she was the only child of Necker and his irreproachable but colourless wife, who as Suzanne Curchod had loved the young historian Gibbon at Lausanne. Germaine was an extraordinarily precocious child, figured at receptions at eleven, and grew up in an atmosphere of admiration. She ever loved and respected her mother, but her father throughout life she loved on this side idolatry. Rousseau, Clarissa, and Werther were her first idols, she was steeped in the sensibility of the age, and already in her girlhood she wrote romantic comedies, tragedies, novels, essays, and one book which has lived, *Lettres sur Rousseau* (1789). She was fifteen when her father was dismissed from office for publishing his famous *Compte Rendu*, and withdrew into retirement, carrying with him the admiration of the whole of France. A great marriage was desired for the young heiress, and it seems certain that William Pitt on his visit to the Continent in 1783 was a suitor for her hand, and one favoured especially by her mother, although displeasing to herself. At length after long negotiations she married on January 14, 1786, the Baron de Staël-Holstein, whom Gustavus III. of Sweden pledged himself to retain as his ambassador at Paris. He was drowned in debt, and seventeen years her senior, but proved an inoffensive and easy husband. She bore him two sons (1790 and 1792) and a daughter (1797), but to protect her fortune separated formally from him in 1798, although she hastened dutifully to his bedside when he died four years later. The deepest feeling of her heart was a woman's craving for love, and those who can read between the lines of *Delphine* (1802)—the real romance of her life—will understand how little she had realised her youthful dream in marriage. But hardly less deep within her heart was the desire to shine and to please, and this she gratified to the full as a society-queen in the brilliant world of the Paris of her day. She lacked the special charm of beauty, she was careless of dress, impulsive and abrupt in manners, but her vast capacity for enthusiasm and the passionate intensity of her affections gave force and colour to her rich and versatile character, and combined to form a personality whose influence was irresistible. Society and conversation were a necessity of her nature, and called forth from the depths of her heart that flowing impromptu eloquence that subdued all hearers into admiration. The simplicity and directness of her thought was no less remarkable than its impetuosity and force, and words and ideas flowed from her lips in a kind of glorified improvisation that suggested at once the exalted inspiration of the prophet, the refined sensibility of the woman, and the clear understanding of the thinker. 'Were I queen,' said Madame de Tessé, 'I would order Madame de Staël to talk to me for ever.'

She shone brilliant and solitary in Paris, but many envious enemies—her father's before her own—embittered her triumph. Meanwhile the dawn of revolution promised to open up new horizons for France, but events moved quickly to their inevitable end, and Necker's elevation and unregretted fall but hastened on the dénouement of the tragedy. She mistrusted Mirabeau, and saw with sinking heart the ruin of the monarchy, but only quitted Paris for Coppet at the last moment, in September 1792. Indeed she

risked her own life with characteristic unselfishness to save some of her friends, and only fled when it was impossible longer to remain. From Coppet she went to England, where at Mickleham in Surrey she was surrounded by Narbonne, Talleyrand, Montmorency, Lally, and Malouet, and cast her unailing spell over that warm-hearted little pride Fanny Burney. Even here, victim of the Revolution as she was, Necker's daughter was shunned by the royalist exiles; still with all her mortifications she acknowledged that she owed to England 'four months of happiness saved from the shipwreck of life.' She joined her husband at Coppet in May 1793, and launched into the world her *Réflexions sur le Procès de la Reine* in the vain hope to save the head of Marie Antoinette. The Terror literally crushed her sympathetic heart, and all work became for a time impossible. Her mother died in May 1794; in September of the same year she found some consolation in a new friendship with Benjamin Constant, which formed an epoch in the lives of both. In May 1795 she returned to Paris, where her husband had re-established himself as ambassador. She prepared for a political rôle by her *Réflexions sur la Paix intérieure* (1795), and published some of the novels of her youth, with an *Essai sur les Fictions*, but the Directory found her inconvenient as a citizen of Paris, and she was advised to return to Coppet in December. Her book *De l'Influence des Passions* appeared in the autumn of 1796: the chapters on ambition and suicide are forced and feeble; those on woman's love, unsatisfied, misunderstood, betray the living heart. She was allowed to return to Paris in April 1797. The young conqueror, Bonaparte, overawed her with a vague pre-eminence of fear. He disliked clever women, and received her friendly advances with such studied coldness that their mutual feelings soon turned to hatred. In April 1800 she published her famous book *De la Littérature considérée dans ses Rapports avec les Institutions sociales*—a thesis of 600 pages on that perfectibility of the human mind which finds its consecration in the liberty guaranteed by republican institutions.

She returned again to Paris in March 1802, when her salon was more brilliant than ever. Here the vulgarity and charlatanism of the Napoleonic régime were heartily laughed at, but at length the epigrams of Constant, her own friendship with disaffected men like Moreau and Bernadotte, and last of all the appearance of Necker's *Dernières Vues de Politique et de Finances* exhausted the patience of Napoleon. And now commenced that ten years' duel between Caesar and a single woman of genius, which drew towards her the pity and admiration of the world. If she does pose somewhat too complacently throughout as the victim of a tragedy, and if there is still something of theatrical exaltation in her exile's despair, it cannot be denied that Napoleon belittled himself by his malignant and spiteful persecution. Already in 1802 her friends fell off from her under Napoleon's displeasure, and in the autumn of 1803 she received orders to keep forty leagues from Paris. Her husband had died in May 1802, and she was now free to marry Constant, but she determined not to convert a slave into a master, and in December 1803 set out with her children for Weimar. Schiller received her with warmth, but Goethe paid a more unwilling homage. She dazzled the whole court with the extraordinary volubility and force of her ideas, yet even the generous Schiller breathed a sigh of relief when she departed for Berlin. Here she made acquaintance with the erudite August Schlegel, afterwards to be added to the circle of intimates at Coppet to the displeasure of Sismondi, Bonstetten,

and the rest. She next turned her steps towards Vienna, but on the way learned of her father's death, and at once returned to Coppet, her heart weighed down under the deepest grief of her life. She found relief during the spring in writing the sincere and touching eulogy, *Du Caractère de M. Necker et de sa Vie privée*. Then she set out for Italy accompanied by Schlegel, Wilhelm von Humboldt, and Bonstetten, and returned to Coppet in June 1805 to write *Corinne*, a romance unfolded in a journal of travel mingled with meditations on history, the heroine again herself, exalted indeed, but recognisable down to close personal traits. It at once brought her a European fame, and it revealed to Frenchmen all the mystery and charm of Italy.

She visited Germany again in the end of 1807, thought for a moment of travelling in America, and about this time began to turn for consolation to religion, or at least to what the Duc Victor de Broglie terms with a happy and pious vagueness, 'un latitudinairisme piétisme.' Her famous book *De l'Allemagne* was finished in 1810, submitted to the established censorship, and then entrusted to the same publisher who had printed *Corinne*. To see it through the press she established herself at Chammont, and ten thousand copies had already been struck off when the whole was seized by Savary and destroyed, and herself ordered instantly to Coppet. It was the crowning act of Napoleon's malignity, but fortunately her son had preserved the manuscript, and at length the work was safely published by John Murray at London in 1813. But her exile had now become a bitter reality, and she found herself encompassed with spies, the post-masters between Coppet and Geneva forbidden to supply her with horses, and her faithful friends, Montmorency, Schlegel, Madame Récamier, and others exiled or imprisoned for visiting her. Overwhelmed with despair, she escaped secretly to Berne, and thence made her way through Innsbruck, Vienna, and Galicia to Russia, then to St Petersburg and Stockholm, and finally in June 1813 to London. The progress of the enemy of Napoleon through the northern capitals was a continuation of triumph, and in England she found herself the object of an unbounded admiration that reached its climax in the enthusiasm which followed the publication of *De l'Allemagne*, the most finished of all her works. She made acquaintance with Lord Grey, Lord Lansdowne, Sir James Mackintosh, Lord Holland, Canning, Willherforce, and Byron. The last, while acknowledging his admiration for the writer, has not spared some characteristic sneers against the woman. The autumn of 1814 found her again at Paris. She was received with the utmost cordiality by Louis XVIII., but it sickened her patriotic heart to see that French freedom was the work of strangers whose foreign uniforms darkened the streets of Paris. Her old friends flocked to her salon; Madame Récamier, Madame de Krüdener, and Benjamin Constant, already twice married, disillusioned, and forty-eight years old, but still in love with her, although her own feeling had long subsided into quiet affection; even the time-serving Talleyrand, who had so long forgotten his early friendship, was generously forgiven. She returned for the summer to Coppet, but spent the winter of 1814-15 again at Paris, where the two millions which Necker had left in the Treasury was honourably paid back to her. The escape of Napoleon from Elba drove her hurriedly from Paris, and after Waterloo she did not return to witness the humiliation of the second occupation. She spent the winter in Italy for the sake of the health of Albert de Rocca, whom she had met about the end of 1810 at Geneva, and married secretly, though

twenty-one years his senior, in the beginning of 1811. Her daughter Albertine married the Duc Victor de Broglie in February 1816. Her own health now began to give way, but she forgot her sufferings in the devoted affection of her husband, himself in enfeebled health and destined for an early grave. She died without pain on the morning of 14th July 1817, and was buried at her father's feet at Coppet. Her surviving son and daughter made public the marriage with Rocca, and received as a brother the son she had borne him. They published with pious care in 1818 her unfinished *Considérations sur la Révolution Française*, which Saint-Beuve thought her finest work, and in 1821 the *Dix Années d'Exil*.

A complete edition of her works was issued by her son, the Baron Auguste de Staël (17 vols. 1820-21), with a Notice by her cousin, Madame Necker de Saussure.

Madame de Staël has not maintained the place unanimously given her by her contemporaries and her immediate posterity, but she still remains as a woman and a writer a unique phenomenon in the history of letters. She had little creative power, was careless of style, and was steeped in a sensibility long since happily forgotten; but her remarkable personality can never lose its attraction, and her work remains entire in its influence on the one side on Royer-Collard, Guizot, and the Doctrinaires, and on the other on Lamartine and the whole Romantic movement in France. She has given an endless subject to the ablest critics of France. Sainte-Beuve says 'she has been one of the idols of my youth, and that idolatry I have not abjured.'

See the elaborate Lives by Stevens (2 vols. Lond. 1880), Lady Blennerhassett (3 vols. Berl. 1887-89; Eng. trans. 3 vols. 1889), and the shorter studies by Bella Duffy (1887) and Albert Sorel (1890; Eng. trans. 1892). See also Gérando, *Lettres inédites et souvenirs biographiques de Mad. Récamier et de Mad. de Staël* (1868), and the Comte d'Haussonville's book, *Le Salon de Madame Necker* (1882; trans. 1882). Criticisms will be found in Sainte-Beuve's *Portraits de Femmes*, and in the collected studies of Caro, Seherer, and Brunetière. See also D. G. Lang, *Mme. de Staël - Her Life as revealed in her Work* (trans. from French, 1926).

Staff, in a Military sense, consists of a body of skilled officers, whose duty it is under orders from the commanding officers of various grades to arrange the movements and supply of the various bodies which go to make up an army, and to issue the orders of the commander of each body. Regimental officers deal personally with the men under their command. Staff officers deal only with the commanders of the larger units into which the troops are grouped for tactical or administrative purposes. Thus in arranging the march of an army, the officers of the *Army Staff* would, amongst other things, allot the available roads to the divisions of the army, and to the extra-divisional or 'Army' troops. The officers of each *Divisional Staff* would direct the order in which their brigades, &c., would move along those roads. The *Brigade Staffs* would give more detailed orders, arranging what battalions were to form advanced guards, &c., while the *Regimental Staffs* of these battalions would order the actual formation to be assumed by them under the command of their *Regimental Officers* (captains and lieutenants). On the staff of each army corps and division there are representatives of the Artillery, Engineers, Army Service Corps, Medical Staff, Ordnance Store Corps, Veterinary and Pay Departments, Chaplains, Post-office, and Military Police. A good staff is all-important to the success of a military enterprise.

The *General Staff* of an army comprises the general in actual command, with the subordinate generals commanding the several divisions and brigades; the assistants to these—viz. the officers of the adjutant-general's department—i.e. the adjutant-general, his deputy, assistants, and deputy-assistants; the officers of the quartermaster-general's

department; the brigade-majors; the provost-marshal; and the judge-advocate—the functions of all of whom are described under their respective heads. An officer before he can be appointed to the general staff must have passed the Staff College or become qualified for the staff by having been employed as a staff officer with a force on active service. The *Personal Staff* consists of the aides-de-camp and military secretaries to general officers. These officers are appointed, within certain limits, by the generals whom they serve. The *Regimental Staff* of a battalion of infantry or regiment of cavalry consists of the lieutenant-colonel commanding, the adjutant, quartermaster, surgeon, veterinary surgeon, and transport officer.

In 1906 an army order was issued for the formation of a *General Staff* for the British army. See *ARMY (Army Administration)*.

Staff Corps.—During the wars of Wellington the generals and staff officers were aided by a staff corps composed of intelligent officers and men who performed engineering and siege duties, made reconnaissances, and executed other necessary labours for which regimental officers or soldiers were unsuited. This corps died out after the peace. The whole body of officers (British) of the Indian army was until 1902 designated the Indian Staff Corps, but the term thus used was a misnomer, and has been dropped; but the Indian army has a staff on the lines of the British.

In the Navy the staff of a fleet consists of the captain of the fleet (who is chief of staff), Flag-officers (q.v.), the Flag-lieutenants (q.v.), and secretaries; also of the inspector-general of hospitals (see *ARMY, NAVY*), and an inspector of machinery. In 1912 a War Staff for the Navy was formed, corresponding to the General Staff of the Army. It is a development of the Naval Intelligence Department, branches of which dealt with foreign intelligence, mobilisation, trade, war schemes respectively.

Staff, LEOPOLD (b. 1878), Polish poet, started his poetical career with his *Dreams of Might and Power*, and has written an epic *Master Twardowski*, and a number of lyrics.

Staffa (Scand., 'pillar-island'), a celebrated islet on the west of Scotland, lies 4 miles SW. of Ulva, 6 N. by E. of Iona, and 54 W. of Oban. It

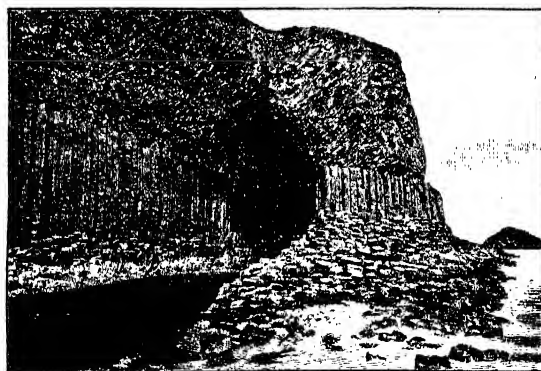

in the lee of the prevailing winds, is a tract of low shore, stretching out in beaches, and forming a landing-place; but elsewhere the coast is girt with cliffs from 84 to 112 feet high. Regarded in section, the rocks show themselves to be of three kinds—conglomerated tufa, forming the basement; columnar basalt, arranged in colonnades, which form the façades and the walls of the chief caves; and amorphous basalt, overlying the columnar basalt, but pierced here and there by the ends of columns and by angular blocks. The most remarkable feature of the island is Fingal's or the Great Cave, the entrance to which is formed by columnar ranges on each side, supporting a lofty arch. The entrance is 42 feet wide, and 66 feet high, and the length of the cave is 227 feet. The floor of this marvellous chamber is the sea, which throws up flashing and many-coloured lights against the pendent columns, whitened with calcareous stalagmite, that form the roof, and against the pillared walls of the cave. First described (in *Pennant's Tour*) by Sir Joseph Banks, after a visit in 1772, Staffa has since been frequently visited—among others by Fajfjas de St. Fond, Wordsworth, Kents, Scott, Mendelssohn, Tennyson. Traces of a chapel have been found.

Staff College. See *MILITARY SCHOOLS*.

Stafford, the county town of Staffordshire, on the left bank of the Sow, 3 miles above its junction with the Trent, and 25 miles SSE. of Crewe, 29 NNW. of Birmingham, and 133 NNW. of London. St Mary's Church, formerly collegiate, is a good cruciform structure, with an octagonal tower. Transition Norman to Decorated in style, it was restored by Scott in 1844-47, and in 1878 received a bust of Stafford's chief worthy, Isaac Walton, who was baptised in its font. St Chad's, Norman, was very thoroughly restored during 1855-85; and there are also King Edward's grammar-school (1550; rebuilt 1862), the town-hall (1798), a free library (1882), the William Salt Library (1874), the Clement Wragge Museum, the infirmary (1766), the county lunatic asylum (1818), &c. Stafford Castle, finely situated on an eminence outside the town, which commands a magnificent view, is an unfinished castellated pile. It was built by Sir G. Jerningham in 1810-15, successor to a Saxon fortress of the Princess Ethelfleda, and to a later Norman stronghold, which was finally taken by the parliamentarians in 1643, and demolished. Boot and shoe making is the staple industry, and Stafford is an important railway centre. Chartered by King John, it returned two members from Edward I.'s reign till 1885, one till 1918. Pop. (1851) 11,829; (1871) 14,437; (1901) 20,894; (1921) 28,632.

Stafford, WILLIAM HOWARD, VISCOUNT (1614-80), a Roman Catholic nobleman, beheaded on Tower Hill as a victim of the perjuries of Titus Oates (q.v.).

Staffordshire, a west midland county of England, bounded by Cheshire, Derbyshire, Leicestershire, Warwickshire, Worcestershire, and Salop. Measuring 54 by 35 miles, it has an area of 1158 sq. m. or 741,318 acres. The only hilly district is in the north, where the wild 'Moorlands,' the southern extremity of the Pennine range, extend from north-west to south-east in long ridges, separated by deeply-cut valleys, and subside as they

Fingal's Cave, Staffa.

forms an oval uneven tableland, rising at its highest to 144 feet above the water, $\frac{1}{2}$ mile in circumference, and 71 acres in area. In the north-east,

near the valley of the Trent. Several points exceed 1500 feet above sea-level, but Axe Edge Hill (1756) falls just within Derbyshire. The rest of the county is gently undulating, with the low upland of Cannock Chase in the centre. The Trent, flowing first south-eastward through the interior, and then north-eastward along the Derbyshire border, is the chief river, and receives the Sow, Tame, Blythe, and Dove. New Red Sandstone occupies nearly three-fourths of the total area; and in the north and south are the Pottery and Dudley coalfields, which, besides containing nearly 600 collieries, yield also (especially the northern one) vast quantities of ironstone (see IRON). The climate is cold and humid, with a rainfall of 36 inches; and, though more than four-fifths of the area is arable, much of the soil is cold and clayey, and agriculture is in rather a backward condition. In the 'Potteries' of North Staffordshire, embracing Stoke-on-Trent, Newcastle-under-Lyme, &c., most extensive manufactures of china and earthenware are carried on (see POTTERY); and in the 'Black country' in the south, with Wolverhampton and Walsall, iron is very largely manufactured in all its branches. The Burton breweries are world-famous. There is a perfect network of railways and canals. For parliamentary purposes the county has been divided since 1918 into seven divisions, each retaining one member—Leek, Burton, Lichfield, Kings-winford, Cannock, Stafford, and Stone. The county boroughs are Burton-on-Trent, Smethwick, Stoke-on-Trent, Walsall, West Bromwich, and Wolverhampton. Stoke-upon-Trent, Hanley, Burslem, Longton, &c., were united in 1910 as the county borough of Stoke-on-Trent. The other municipal boroughs are Lichfield, Newcastle-under-Lyme, Stafford, Tamworth, and Wednesbury. Pop. of county (1801) 242,693; (1841) 509,472; (1881) 981,009; (1921) 1,349,225. Staffordshire has no great wealth of antiquities, and has been the scene of no battles more important than Blore Heath (1459) and Hopton Heath (1643). Among its natives have been Lord Anson, Ashmole, Dr Johnson, Thomas Newton, Cardinal Pole, Earl St Vincent, Isaac Walton, Josiah Wedgwood, Arnold Bennett.

See county histories by Plot (1686), Erdeswick (1717), Shaw (1798-1801), R. C. Garner (1844-60), and the Victoria History (1908-12); the *Proceedings* of the William Salt Archaeological Society (1880 *et seq.*); *Collections for a History of Staffordshire* (vol. xii. 1893); and works cited in Summ's *Bibliotheca Staffordiensis* (Lichfield, 1894).

Stag is the male of the Red Deer (q.v.). In Scotland the pursuit of the stag is mainly by deer-stalking, a long and laborious approach on foot allowing at best a chance of a rifle shot at the deer from a place of concealment. In England wild red deer are still hunted on horseback on Exmoor. The hounds are like foxhounds (see BUCKHOUNDS), and a good run may extend to 20 or 30 miles. The hunting season is 12th August - 8th October, and 25th March - 10th May. See DEER FORESTS, EXMOOR FOREST.

Stag-beetle (*Lucanus*), a genus of Lamellicorn beetles, nearly allied to the Scarabæes. The males are remarkable for the large size of their mandibles, the branching of which in *L. cervus* and *L. elaphus* has suggested stags' antlers. The common European Stag-beetle (*L. cervus*) is a large formidable-looking insect, the males being fully 2 inches long, and able to give a sharp bite with their strong mandibles. It flies about in the evening in the middle of summer, chiefly frequenting oak-woods. The larva feeds on the wood of the oak and willow, and is injurious to the trunks of trees, into which it eats its way very rapidly. It is supposed by some to be the *Cossus* of the ancient

Romans, much esteemed by them as a delicacy. It lives for several years before undergoing its transformations (see BEETLE). Most species of

Stag-beetle (*Lucanus cervus*).

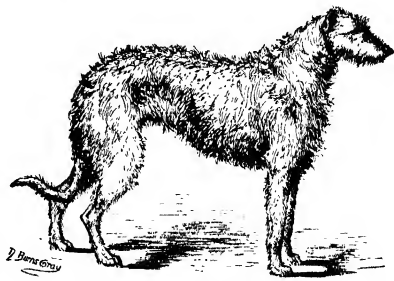

Lucanus, and of the nearly related genus *Passalus*, are some shade of brown, but the tropical forms are often brilliant.

Stage. See DRAMA, THEATRE.

Stage-coach. See COACHING.

Staggers is a popular term applied to several diseases of horses. Mad or Sleepy Staggers is inflammation of the brain, a rare but fatal complaint, marked by high fever, a staggering gait, violent convulsive struggling, usually terminating in stator; it is treated by bleeding, full doses of physic, and cold applied to the head. Grass or Stomach Staggers is usually occasioned by overloading the stomach and bowels with tough hard grass, vetches, or clover, a full meal of wheat, or other indigestible food. It is most common in summer and autumn, is indicated by impaired appetite, dull aspect, unsteady gait, and is remedied by full doses of purgative medicine, such as six drachms of aloes and a drachm of calomel rubbed down together, and given in a quart of thin, well-boiled gruel. Frequent clysters, with hand-rubbing and hot water to the belly, are likewise useful. Where the dullness increases, non-alcoholic stimulants should be given. See also HYDATID.

Staghound, a name applied both to the Buckhound (q.v.) and to the Scottish deerhound. The latter breed has been established in Scotland from time immemorial, and has probably sprung from the same source as the Irish wolfhound and the

Deerhound, 'Rossie Ralph.'

smooth greyhound. A contest between two deerhounds is vividly described in Ossian's poems. The breed seems to have been in danger of extinction about the beginning of the 19th century, when crosses of fresh blood were tried, and the

breed successfully revived. Owing to the altered conditions of sport the staghound can only be looked on now as an ornamental dog, as he is rarely used for pulling down the wounded deer, the purpose for which he was originally kept. The deerhound is an immense shaggy dog, standing nearly 30 inches high in some cases, and has a peculiar swing in his action suggestive of great speed, with a keen, determined expression. In conformation the deerhound is similar to the greyhound, but with more bone and power; the head is long, with powerful jaws. The body is covered with wiry hair about 3 inches long. The colour varies from dark gray to white. As an ornamental and graceful dog the deerhound is without an equal, and as a rule combines good temper with his other companionable qualities.

Stagira. See ARISTOTLE.

Stahl, FRIEDRICH JULIUS, writer on law and jurisprudence, was born of Jewish parents at Munich on 16th January 1802. He became a Protestant when seventeen, studied law at the universities of central Germany, and in 1830-37 published his greatest book, *Die Philosophie des Rechts*. In this work, improved in 1854-56, Stahl proclaimed the doctrine that belief in the revealed truths of the Christian religion is the only satisfactory basis of jurisprudence and politics. From 1832 to 1840 he taught alternately at Erlangen and Wurzburg, and in 1840 was called to the chair of Philosophy of Law at Berlin. There he acquired an influential position as a leader of the 'Junkers' in the Chamber of Magnates (of which he was a life-member) and as an uncompromising opponent of all political change, and the mouthpiece of a stern Lutheranism in the church assemblies. He died at Bruckenaue (Bavaria) on the 10th August 1861, a determined opponent to the last of the various liberal parties in both civil and ecclesiastical politics. *Der Christliche Staat* (1847) advocated a doctrine very similar to the 'divine right of kings.' He wrote several other books.

Stahl, GEORG ERNST, author of the Phlogiston (q.v.) theory in chemistry and of the theory of Animism (q.v.; and see ANIMA MUNDI) in medicine, was born at Aushach on 21st October 1660, and held successively the appointments of court-physician (from 1687) to the Duke of Saxe-Weimar, professor of Medicine (from 1694) in Halle, and body-physician (from 1714) to the king of Prussia. He died at Berlin on 14th May 1734. His chemical theory was expounded in *Experimenta et Observationes Chemicae* (Berl. 1731), and his medical in *Theoria Medica Vera* (Halle, 1707).

Ståhlberg, KAARLO JUHO, first president of the Finnish republic, born in 1865, was professor of Law at Helsingfors, minister of commerce (1905), prime-minister, president of the diet (1914), and president of the Supreme Court. A progressive, with the support of social democrats and agrarians, he defeated General Mannerheim, the White leader, in the presidential election, July 1919, and held office till 1925.

Stained Glass. See GLASS (PAINTED).

Stainer, JAKOB, violin-maker, was born at Absam near Hall in Tyrol on 14th July 1621, and was apprenticed to a maker of stringed musical instruments at Innsbruck. There is a legend, devoid of foundation, however, that he worked under some of the Amati at Cremona. He did somehow learn the secret of the Italian method of constructing violins, and so won a reputation that passed beyond Germany, into Italy and England, and lasted for more than a century. At the present day his violins are valued as curiosities, but are not esteemed of use by practical musicians. Stainer died in 1683, insane, and, in spite of grand-

ducal favour, in a state of poverty. There is a Life by Ruf (Innsbruck, 1872).

Stainer, SIR JOHN, organist and composer, was born in London, 4th June 1840, and became a chorister in St Paul's Cathedral. He was made organist of Magdalen College at Oxford in 1859, took degrees in arts and music, in 1872 became organist of St Paul's, and in 1880-99 was professor of Music at Oxford. In 1888 he was knighted. Among his works are the cantatas *The Daughter of Jairus* (1878) and *The Crucifixion* (1887), a *Treatise on Harmony*, and a *Dictionary of Musical Terms* (with Barrett). He died at Verona, 31st March 1901.

Staines, a picturesque town of Middlesex, on the left bank of the Thames, 6 miles SE. of Windsor and 19 WSW. of London ($35\frac{1}{2}$ by river). It took its name from the 'London Stone' (1280), marking the county boundary; it has a granite bridge by Rennie (1832); and in the neighbourhood are Rinnimede, Egham, and Cooper's Hill, all noticed separately. The reservoir (begun 1898) to store the flood-waters of the Thames valley for the supply of London (in use since 1904) has an area of 424 acres with a total capacity of 3,338,000,000 gallons. Pop. 7000.

Stair, a village in central Ayrshire, gives the title of Earl to the ancient Scottish family of Dalrymple. A Dalrymple of Stair was among the Lollards of Kyle summoned before James IV.; his great-grandson was one of the earliest to make public profession of the Reformed doctrines.—James Dalrymple of Stair (1619-95) studied at Glasgow University, served in the army, and acted six years as Regent in Philosophy at Glasgow, next joined the bar (1648), and scarcely ten years after was recommended by Monk to Cromwell for the office of a lord of session, as 'a very honest man and a good lawyer.' He was confirmed in office, and created a Nova Scotia baronet in 1664. It was the death of his daughter Janet in 1669, within a month of her marriage to Dunbar of Baldoon, that gave Scott the tragic plot of *The Bride of Lammermoor*. His wife, who survived till 1692, was credited in Galloway with being a witch. About the close of 1670 Dalrymple was made president of the Court of Session and member of the Privy-council, and during the next ten years, if he distinguished himself by reforms in legal process, he must have winked hard at much wickedness and illegality in high places. The Duke of York took up the work of government at Edinburgh in 1679, and Dalrymple, who honestly hated Popery at least, soon found himself obliged to retire to the country. In his leisure he prepared his famous work, the *Institutes of the Law of Scotland*. His wife and his tenants were devoted to the Covenant, and accordingly he soon became involved in a fierce dispute with Claverhouse, who was ravaging Galloway with a military commission. In October 1682 he found it necessary to flee to Holland, returned with the Prince of Orange, and soon after was restored to the presidency in Lockhart's room. He was created Viscount of Stair, Lord Glenluce and Stranraer in 1690, was much molested by factious attacks during his last years, and died at Edinburgh, 25th November 1695. See J. G. Mackay's *Memoir* (Edin. 1873), and *The Stair Annals*, edited by J. Murray Graham (Edin. 1875).—His second son was Sir James Dalrymple (q.v.). Collaterally connected was the learned Lord Hailes (q.v.), whose own younger brother was the hydrographer Alexander Dalrymple (q.v.).

The eldest son, Sir John Dalrymple, first Earl of Stair, was born in 1648, and followed the hereditary profession of his family. He came into violent collision with Claverhouse in Galloway, and was flung into prison in Edinburgh and heavily fined,

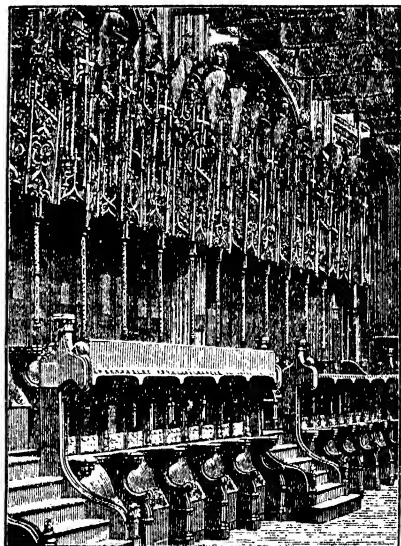

but early in 1687, by a remarkable turn in the royal policy, 'the springs' of which Wodrow prudently leaves 'to the civil historian of the period,' he had all his charges remitted, and became king's advocate, Lord Justice-clerk the next year. He acquiesced easily in the accession of William, became Lord Advocate, and for some years as Secretary of State had the chief management of Scottish affairs. On his shoulders, therefore, with Brendalbane and the king, mainly rests the infamy of the massacre of Glencoe (q.v.). He was created Earl of Stair in April 1703. He took an active part in the debates and intrigues that preceded the carrying of the Treaty of Union, and indeed fell a victim to his zeal in its cause, dying suddenly the morning after a long and vehement debate, 8th January 1707. 'He was,' says Defoe, 'justly reputed the greatest man of counsel in the kingdom of Scotland.' See Omond's *Lord Advocates of Scotland* (vol. i.), and J. Murray Graham's *Stair Annals* (2 vols. 1875).—John Dalrymple, second Earl of Stair, was the second son of the second viscount and first earl, and was born at Edinburgh, 20th July 1673. At eight he shot his elder brother dead by accident at the family seat of Carscough Castle in Wigtownshire. He was brought up in Holland, studied at Leyden, and early attracted the notice of the Prince of Orange. He volunteered for service, was present at Steenkerk, and by 1701 was lieutenant-colonel in the Scots foot-guards, in 1706 colonel of the Cameronians. He was aide-de-camp to Marlborough in 1703, and showed conspicuous courage at Venlo. He commanded a brigade of infantry at Ramillies, and was rewarded with the colonelcy of the Scots Greys in August 1706. He distinguished himself greatly at Oudenarde (1708), was promoted major-general, and commanded his brigade at the siege of Lille and at Malplaquet. His rank of general he received in 1712, after which he retired to Edinburgh to intrigue for the Hanoverian succession. In 1714 he married the beautiful and strong-willed widow, Eleanor, Viscountess Primrose, forcing her consent for the sake of her reputation by the artifice of concealing himself in her house and showing himself at her bedroom window. This audacious ruse afforded a foundation for Scott's story, *My Aunt Margaret's Mirror*. On the accession of George I. Stair returned to favour, and soon after was appointed ambassador to Paris. He lived with splendid magnificence, yet checkmated at every turn the Pretender and the vast schemes of Alberoni. Recalled in 1720 with fortunes sadly impaired, he mainly devoted himself thereafter to agricultural improvements, introducing turnips and cabbages, while his clever wife became a leader of society in Scotland, and helped to make Moffat the fashion. On Walpole's fall he was made field-marshal (1742), and governor of Minorca, without residence. He took the command of the army which was to support Maria Theresa in conjunction with a Dutch and Austrian force, but had already lost ground strategically in presence of Noailles, when George II. came to take command in person. Stair showed his usual courage at Dettingen, but after the victory was allowed to resign. He died at Queensberry House, Edinburgh, 9th May 1747. See the *Annals* by Graham.

Stalactites, Stalagmites. See CAVE, LIME-STONE.

Stalin (or DZHUGASHVILI), JOSEPH, Russian politician, the son of a peasant, was born in 1879 in the Tiflis region of Georgia. From his youth he harboured revolutionary tenets, for which he was expelled from college and repeatedly imprisoned and exiled. He edited the Bolshevik organ *Pravda* in 1917, and served with Lenin in stout support of the Communist party, attaining chief power in 1926.

Stalingrad, formerly TSARITSYN, a great port and industrial town of Russia, above the last great bend of the Volga; pop. 100,000.

Stall, the technical English name for the seats in churches reserved for the clergy and choir, and usually lining the choir or chancel on both sides, sometimes in two or more rows. In cathedrals and other large churches they are generally enclosed at the back with a high screen, and are often surmounted with pinnacled canopies of tabernacle work, the backs and arms being usually carved in a more or less ornate manner. At the west end are often 'return' stalls, facing east, for the dean, warden, chancellor, or other dignitaries.

Stalls, Westminster Abbey.

In Henry VII.'s Chapel (1502-20), Westminster Abbey, the dark oak choir stalls, with their finely-carved misericords (q.v.), are appropriated to the Knights of the Bath, and the lower seats to their squires; and each stall bears its occupant's armorial bearings in brass, with a sword and banner above. At Winchester, Chester, Windsor, and King's College, Cambridge, are also fine examples of stalls.

Stallbaum, GOTTFRIED (1793-1861), born near Delitzsch in Saxony, was rector of the Thomas-schule, and professor at Leipzig. He edited Herodotus, Plato (12 vols. 1821-25), and other classics.

Stalybridge, a cotton-town of Cheshire, with machine-shops, &c., 7½ miles E. by N. of Manchester. Made a municipal borough in 1857, it was a parliamentary borough (partly in Lancashire) from 1867 to 1918. Pop. 25,000.

Stambolov, STEPHAN NIKOLOV. Bulgarian statesman, was born, the son of an innkeeper, in 1854, at Trnova, studied there and at Odessa, and bore a part in the rising of 1875-76. He held office during the Russian occupation after the war of 1878, and, now an advocate in Trnova, became conspicuous as a radical leader in the new National Assembly. He was the chief member of the regency

after Prince Alexander's abdication (1886), and strenuously opposed all Russian partisans. After the election of Ferdinand he was premier 1887-94, and ruled with as little regard for the prince as for the Assembly. Forced then to retire, on 15th July 1895 he was attacked by assassins and savagely mutilated, and died on the 18th. See Life by A. Hulme Beaman (1895).

Stamboul. See CONSTANTINOPLE.

Stamens constitute the male portion of the flower (q.v.). Each stamen consists of a stalk or filament and a pollen chamber or anther. The *androecium*, as the group of stamens in a flower is termed, is situated between the parts of the floral axis occupied by carpels and petals. But their position on the axis, whether below the carpels, as is most commonly the case, or on a level with them, or above them, varies, and is used as an aid to classification. When they are inserted on the thalamus (flower receptacle) below the carpels the flower is said to be *hypogynous*; when, carried upwards by the continued growth of the outer part of the flower receptacle, they are inserted on the same level as the carpels, then the flower is *perigynous*—when, carried up still farther, they are inserted above the carpels, the flower is *epigynous*. If the stamens are adherent to the petals they are *epipetalous*; if adherent to the pistil (united carpels) they are *gynandrous*. If the filaments only are more or less coherent (mallow) the stamens are *monadelphous*; if united into two bundles (pea) they are *diadelphous*; if only the anthers cohere, then the stamens are *synanthrous*. The stamens vary in number from a single one in a flower to as many as several hundreds. These variations also are used in classification. When the stamens are *definite*—i.e. ten or less in number—the individuals are inserted alternately with each of the petals, or each of the sepals, or alternately with both whorls. If they are less in number than the petals or sepals of the flower, then their position varies. When there is more than one whorl of stamens, then the individuals of each whorl alternate with the individuals of the next whorl below it. Often the full number of stamens, that comparison with other flowers of the same order would lead us to expect, is not present; but usually aborted traces of them may be seen. Thus most of the Scrophulariaceae are peculiar in having only four stamens, but the fifth is represented by a minute scale. Remnants of this description are called *staminodes*.

The stamens are commonly said to be metamorphosed leaves. A leaf is often defined as an appendage of the axis or stem; this, however, is only an assertion of the general homology, or similarity of origin, of the two kinds of appendages. Often, too, stamens are said to be altered flower-leaves—i.e. petals. But this is a case of putting the cart before the horse. Stamens very commonly become petaloid, as, for instance, when a flower becomes 'double' under cultivation, and in a few cases in the natural state—the white water-lily, for instance. In all such cases there may be seen in the same blossom a complete series of transition forms between stamens and petals. This indicates the homology of the two kinds of appendages, but of itself gives no evidence as to which form is the precursor of the other. But the fact that the Gymnosperms (q.v.), conifers for example, which are older forms and are less highly developed than the true flowering plants, have stamens but not petals, indicates that the petals of the Phanerogams are a more recent evolutionary introduction than stamens. The further facts that the characteristic colour of stamens is yellow, and that the simplest, lowest flowering plants have yellow flowers, are

again examples of evolution leading to the same conclusion.

The anther which contains the fertilising pollen is the essential part of a stamen. The pollen is set free by the splitting—*dehiscence*—of the anthers. The mode of dehiscence is sometimes characteristic of the plant. Thus the anthers of the Rhododendron open and shed their pollen through a small circular pore at the upper end of each lobe; and in a few cases the dehiscence is transverse, or across the anther. But the most usual mode of dehiscence is by a longitudinal slit in each lobe, either on the inner or outer face of the anther.

The time at which the stamens dehisce relatively to the ripening of the stigma is important. For if the anther dehiscence when the stigma is ready to receive pollen, then the flower may be self-fertilised; but if it does not open at that time, then self-fertilisation will be impossible, or nearly so, and that flower must be cross-fertilised. Stamens present numerous modifications of form that are apparently adaptations to the process of fertilisation.

The particular functions of a stamen are the production and liberation of pollen-grains. In comparison with the higher Cryptogams, such as Horse-tails and Lycopods, the pollen is essentially a microspore whose microscopic structure and ultimate development are adapted to terrestrial instead of aquatic or semi-aquatic conditions. In short, whereas the microspore of the Cryptogam produces a prothallus which liberates a free active spermatozoid into the outer world to find its way to the egg by wriggling through water, the pollen-grain is conveyed by wind, insect, or other agent to the stigma of a flower, where it develops a tube that bores its way through the tissues of the style, ovary, and ovule to the egg; then the non motile sperm passes from the tip of the pollen tube to the egg, with which it fuses, as in Cryptogams, and thus effects fertilisation. The recognition of this homology has introduced a change of nomenclature, bringing the parts of the stamen into harmony with structures of the same equality in the Cryptogams. The filament is a microsporophyll, the anther is a microsporangium, the pollen-grain is a microspore, the pollen-tube is a male prothallus, and the generative nucleus or sperm is the equivalent of the spermatozoid; in Gymnosperms the antheridial cell of the pollen-grain represents the antheidium of the male prothallus of Cryptogams, but this is suppressed in Phanerogams.

See FLOWER, SPORE; Aitchison's *Flowers in their Relation to Insects*; Körner and Oliver's *Natural History of Plants*; and the better class of botanical text-books.

Stamford, a municipal borough chiefly in Lincolnshire, but partly also in Northamptonshire, on the Welland, and on the Great North Road, 12 miles WNW. of Peterborough. Hengist is said to have here defeated the Picts and Scots in 449, and Stamford thereafter is notable as one of the Danish 'five boroughs,' for the persecution of its Jews (1190), as having between 1266 and 1334 only missed becoming a rival to Oxford, for its colony of Flemish Protestants (1572), as the birthplace of the earliest provincial newspaper, the *Stamford Mercury* (1695), and for its famous ball-running on 13th November from King John's time until 1839. It has lost ten of its sixteen churches, an Eleanor Cross, two castles, six religious houses, and two hospitals. Existing edifices are St Mary's, with a fine spire; All Saints, with a fine tower and steeple; St Martin's, with Lord Burghley's grave, and, in the churchyard, Daniel Lambert's; a town-hall (1777), corn exchange (1859), literary institute (1842), bridge (1849), Browne's Hospital (5th century), and boys' and girls' high schools (1874-76), 'Burghley House, by Stamford town,' is a magnificent Renaissance pile, dating from 1575, with

a noble park, carvings by Grinling Gibbons, and a great collection of pictures. The trade and industries are mainly agricultural. Chartered by Edgar in 972, and afterwards by Edward IV., Stamford was a parliamentary borough, but lost one of its two members in 1867, and the other in 1885. For good services rendered by the inhabitants at the battle of Loose-coat-field (in 1469) the town seal bears the royal arms. Pop. 10,000.

Stamford, a city of Connecticut, on Long Island Sound, 33 miles by rail N.E. of New York. It has a handsome town-hall, and the hills around are embellished with the summer residences of well-to-do New Yorkers. There are iron and bronze foundries, and manufactories of hats, drugs, sashes and blinds, and Yale locks (see LOCK). Stamford was settled in 1641. Pop. (1880) 11,297; (1890) 15,700; (1900) 15,997; (1910) 25,138; (1920) 35,096. Pop. of the 'town,' including the 'city,' 40,067.

Stamford Bridge, a small town in the East Riding of Yorkshire, on the river Derwent, 9½ miles N.E. of York by rail. It was the scene of the great victory of King Harold (q.v.) over the invading Norwegians under Harold Haardrauda.

Stammering, or STUTTERING, is an infirmity of speech, the result of failure in co-ordinate action of certain muscles and their appropriate nerves. It is analogous to some kinds of lameness; to cramp or spasm, or partial paralysis of the arms, wrists, hands, and fingers, occasionally suffered by violinists, pianists, and swordsmen; to the scrivener's palsy, or writer's cramp, of men who write much. For speech—like writing, fencing, fingering a musical instrument, and walking—is a muscular act involving the co-ordinate action of many nerves and muscles.

The words stammering and stuttering practically denote the same infirmity. Any distinction that may have come to be established in the usage of them respectively would seem to be that stuttering—an onomatopoeic word—is now limited more or less to the futile repetition of sounds, while stammering covers the whole defect, the hesitation, glide, stop, holding on to the sound as well as repeating it. With defective articulation due to malformation—cleft palate, high-roofed mouth, disproportionate tongue and tonsils; or due to affectation and bad habit—interjection of meaningless sounds, lisping, burring, and other such imperfections of speech—we have nothing further to do in this article beyond remarking that a fault of habit may be entirely cured, a faulty formation can only be mended, its irksomeness alleviated.

Since speech at a high degree of excellence is a fruit of advanced civilisation, it is not startling to be told that stammering does not prevail among Negroes in Africa and North American Indians. But when it is proved to be pretty widespread in Prussia, Great Britain and its colonies, and the United States of America, and uncommon in Italy and Spain, the question suggests itself whether languages of Teutonic origin are not more apt to generate stammering than languages of Latin origin. A much larger proportion of males stammer than of females.

Stammering, the chief of the imperfections of speech, may be hereditary, and it may be acquired by imitation. Like yawning, it is infectious. It may be the abiding result of mental strain or shock. Fever may bring it on, epilepsy, hysteria, any nervous affection, temporary failure of health, any excitement, soreness of the mouth. It rarely shows itself earlier than at four or five years of age. It usually begins in youth, but may be produced at any later age. It used to be ascribed exclusively to the organ of articulation, the mouth; to faulty setting of the teeth or the jaws; to the largeness

and thickness of the tongue, its weakness of movement, its excessive vigour. Formerly various operations were performed on the tongue with the idea of freeing it or altering its shape. The tongue was thought to lie too flat on the bottom of the mouth; a plug was inserted to raise it, Demosthenes and the pebbles being referred to. It was one of the secret cures to tell the stammerer to keep the tip of his tongue on the roof of his mouth. An improvement on this was to keep the whole breadth of the tongue lying on the palate. When, by and by, the breathing began to be taken into account, stammering was explained exclusively by reference to the organ of respiration, and the cure was breathing exercises which were kept secret. A later step in the research for the cause and cure of stammering was to take full account of the vocal cords or cushions and the vocal chink.

Stammering occurs in the mouth, the organ of articulation. Its proximate cause is always in the larynx, the organ of voice. Sometimes the lungs, the organ of breathing, complicate the uncertainty and unsteadiness of the vocal cords and the vocal chink in the larynx. A current of air, variously shaped by the mouth as a whole, is what we call a vowel. A stammer on a vowel can only take place in the vocal chink, *rima glottidis*. The sounds called consonants are produced by closures, more or less firm, of contents of the mouth. Thus, *b, p, m, n*, by the closure of the two lips; *f, v*, of the lower lip and upper teeth; *j, ch*, and *sh*, of the teeth; *l* and *th*, tongue and upper teeth; *t, d, n, s, z, y*, tip of the tongue and fore gum; *g* (hard) and *k*, back edges of the tongue and back gum. Stammering may occur at any of these six closures. It is, perhaps, most apt to occur at the labials *b, p*, the dentals *d, t*, the gutturals *g, k*, because for these the closure is firmest. The stammerer has no difficulty in setting lips, teeth, tongue, and gums against each other as required. His difficulty is to relieve the closure, to get at the vowel which is to follow the consonant. The tongue, for example, will not part from the teeth, seems to cling spasmodically to them. Why? Because the current of air, the vowel, does not come at the proper instant through the vocal chink to relieve it. In this way the three observable modes of stammering are explained. If the vocal chink does not open soon enough, there is a stop stammer; if it flutters, there is a stutter; if it opens too soon, there is a glide stammer. But, further, the chest expands and contracts by nervous and muscular energy; and the muscular and nervous machinery of the breastbone, ribs, diaphragm, and upper abdomen are all concerned in that expansion and contraction. These complicated and delicate bellows which supply air under pressure to the organ of voice may be defective, out of order, misused. Their working is to be closely observed in the case of each stammerer. Stammerers, as a rule, breathe badly. They constantly try to speak when their lungs are empty.

Stammering can be cured. It often disappears gradually without effort at cure. Improvement generally takes place as age advances. In some cases resolute endeavour is demanded. A waving motion of the arms, time kept to a baton, were favoured as cures at one time. They were on the lines of the musical methods of cure—intoning, chanting, singing—which were based on the fact that most stammerers can sing. The doctrine of this article suggests as instructions for cure: Regulate the breath. Work for an habitual use of the chest voice—i.e. for deeper, sturdier vibration of the vocal cords—because people generally stammer in a head voice. Take exercise, in a chest voice, on the sounds (seldom vowels) at which a stumble is apt to be made.

Stampa, GASPARA (1523-54), Italian poetess and classical scholar, born at Padua, was a member of the Venetian Academy. She wrote love-poems to Collatino di Collalto, Count of Treviso, who deserted her.

Stamp Act, a measure which required all legal documents in the colonies to bear stamps, proposed by Grenville, then premier, and passed by parliament in 1765. The Americans denied the right of the English parliament, in which they were not represented, to impose taxes upon them, and offered violent opposition. Riots took place in many of the towns, the offices were seized, and the stamped paper destroyed; while a congress of delegates of nine of the states met at New York in October, and passed resolutions claiming for the provincial assemblies the exclusive right of taxation. In the January of 1766 the subject was brought before parliament. In the great debate that followed Burke made his maiden speech, and Pitt, who had been absent for a year, in one of his greatest speeches denied the absolute right of parliament to tax the colonies, as taxation and representation went hand-in-hand. After examining witnesses, chief among them Franklin, the ministry proposed the repeal of the Stamp Act, and carried it on February 21. Thus Pitt's wisdom staved off for a time the breach between England and her colonies.

Stamps, impressed and adhesive, are extensively used for making and verifying payments of money. Stamp-duties were first imposed in England in 1694. For the protection of the public revenue penalties are imposed; thus any person receiving a premium of insurance without issuing a properly stamped policy is liable to a fine. Where the law requires a stamp, an unstamped document cannot be given in evidence in civil proceedings unless the party producing it is willing to pay the duty and an additional penalty. Stamp-duties are a form of indirect taxation, and ought to be moderate in amount; excessive duties on legal documents discourage business. Forgery (q.v.) of stamps is severely punished. See *Highmore, Stamp Taxes* (4th ed. 1921).

Stamps for postal purposes were used, or were proposed to be used, in Paris as far back as 1653. Stamped paper or covers, both with impressed and embossed stamps, were used for official correspondence in the kingdom of Sardinia in 1819-21, several values being provided for. Mr Charles Knight suggested stamped covers for the prepayment of newspaper postage in 1833-34. Stamps or labels, to be gummed or pasted on articles liable to duty, have been in use by the British Revenue authorities ever since 1802, though prior to 1840 they were not issued ready gummed. The use, for postal purposes, of a piece of paper just large enough to bear the stamp, with a glutinous wash on the back rendered adhesive by moisture, was recommended by Sir Rowland Hill (q.v.) as part of his scheme of uniform rates of postage, combined with prepayment, in his pamphlet on post-office reform in February 1837. From the death of Sir Rowland Hill in 1879 till 1891 a pamphlet controversy was carried on by his son and the son of James Chalmers, a Dundee bookseller, by whom, it was asserted, the idea had been fully developed as early as 1834. Chalmers, however, whose scheme was not very workable, had himself recognised Hill's priority.

With the postal reform of 1840 the Franking (q.v.) of letters was abolished in the United Kingdom, and postage-stamps introduced.

The first English postage-stamp (issued on 6th May 1840) was black. The famous 'Mulready envelope,' issued at the same time, and intended to be both cover and stamp, was not a practical success, and was withdrawn the same year.

Stamp-collecting, philately, or timbrology, began to be a common and fashionable hobby about 1861, which spread from Britain to the Continent. Many societies and periodicals devote themselves to it. Some countries have made the stamp-collector a source of revenue by frequent issues of new stamps. Centenaries and events of national importance have been seized as excuses for an elaborate series of artistic designs. Times of war and revolution have added to the number, when ephemeral states and provisional governments have produced a succession of new stamps, often by overprinting those of their predecessors. Rare stamps bring high prices.

See the handbooks issued by the Royal Philatelic Society, London (1879-1920), by Fred. J. Melville, and by D. B. Armstrong; and for forgeries, *Album Weeds*, by the Rev. K. I. Farce. See also *POST OFFICE*.

Ständchen. See SERENADE.

Standing Orders is the name given to permanent regulations made by either House of Parliament for the conduct of its proceedings, and enduring from parliament to parliament unless rescinded. A standing order of the House of Lords when rescinded is said to be *revoked*; in the Commons the corresponding term is *repealed*. In the Lords a motion for making or dispensing with a standing order cannot be granted on the same day that the motion is made, or till the House has been summoned to consider it; and every standing order as soon as agreed to is added to the 'Roll of Standing Orders,' which is carefully preserved and published from time to time. In the House of Commons there was until 1854 no authorised collection of standing orders, except such as related to private bills. In that year a manual of rules, orders, and forms of proceeding relative to public business was drawn up and printed by order of the House. Standing orders are occasionally suspended when it is desirable that a bill should be passed with unusual expedition. See *May, Parliamentary Practice*.

Standing Stones, or monoliths of unheaven stone, erected singly or in groups, are met with

Standing Stones, Lundin Links, Fifeshire.

almost everywhere. They are not in all cases necessarily of ancient origin, but the motive of

their erection may be presumed to have been in general honorary or commemorative either of events or individuals. In certain cases, however, they marked the boundaries of sanctuary or proprietary rights. Single stones, sometimes of great size, are often found standing in sites where no memory or tradition of their purpose exists. Occasionally accident or investigation discloses the fact that they mark the sites of prehistoric burials. They are sometimes arranged in groups of two or four, placed at short distances apart, as at Lundin Links, near Largo, in Fife, three of which are still standing (about 18 feet in height), as shown in the engraving. Such groups, if composed of a large number of stones, may be arranged in the form of circles, or avenues, or alignments, or groups of irregular lines converging slightly at one end. When arranged in the form of circles they are usually considered as belonging to a special class of prehistoric monuments or burial-places known as Stone Circles (q.v.). Other groups of standing stones arranged in lines like those of Carnac (q.v.) in Brittany, however, are as yet undetermined as to their purpose, though they are unhesitatingly assigned to the prehistoric period. Smaller groups than the famous ones of Brittany are found in the north of Scotland, and are sometimes associated with burial cairns, presumably of the age of Bronze. Several of these have been described in Caithness, the largest consisting of about 450 stones disposed in twenty-two rows of about 150 feet in length. In Norway groups of standing stones arranged in triangular and rectangular forms occur, and are known by investigation to be burial-places of the Iron Age. Commemorative monuments of the early Christian time frequently consist of unhewn blocks of stone having short inscriptions cut on their smoother faces, or incised with crosses or symbols. See Ferguson's *Rude Stone Monuments* (1872); T. E. Peet, *Rough Stone Monuments and their Builders* (1912); and other works cited at ARCHÆOLOGY and SCULPTURED STONES. See also CALLERNISH, CROMLECH, DOLMEN, STONEHENGE.

Standish, MYLES, was born at Duxbury, Lancashire, about 1584, served in the Netherlands, and, though not a member of the Leyden congregation, sailed with the *Mayflower* colony to Massachusetts in 1620, and became the champion of the Pilgrims against the Indians. During the first winter his wife died, and the traditional account of his first effort to secure another partner has been made familiar by Longfellow. In 1622, warned of a plot to exterminate the English, he enticed three of the Indian leaders into a room at Weymouth, where his party, after a desperate fight, killed them, and a battle that followed ended in the flight of the natives. In 1632 he settled at Duxbury, Massachusetts, where he died, 3d October 1656. Standish was the military head of the colony, and for long its treasurer. A monument, 100 feet high and surmounted by a statue, has been erected to him on Captain's Hill, at Duxbury. See De Costa's *Footprints of Miles Standish* (1864); Henry Johnson's *Exploits of Miles Standish* (1897).

Stanfield, CLARKSON, marine painter, was born of Irish Roman Catholic parents at Sunderland in 1794, his father being an actor and author. He became a sailor in 1808, was pressed into the navy in 1812, and served for a time in the ship in which Douglas Jerrold was a midshipman. He showed talent both in painting and drawing, and was taken note of by Captain Marryat. Stanfield left the navy in 1818, and thereafter took to scene-painting as a means of earning his bread—at first in the Old Royalty Theatre, and afterwards in Edinburgh and at Drury Lane. While painting for the theatres he by no means neglected

easel-painting. The first picture by him that attracted any considerable notice was 'Market-boats on the Scheldt,' exhibited at the British Institution in 1826. In 1830 he exhibited at the Academy his 'Mount St Michael, Cornwall,' which placed him at once in the foremost rank as a marine painter. In 1823 Stanfield, in conjunction with David Roberts and others, founded the Society of British Artists. Elected A.R.A. in 1832 and R.A. in 1835, he continued to send pictures to the Academy till his death at Hampstead, 18th May 1867. Among his best-known pictures, marked by truth, finish, and poetic feeling, were 'The Abandoned' and 'The Wreck of a Dutch East Indiaman.'

Stanford, SIR CHARLES VILLIERS (knighted 1902), was born at Dublin on 30th September 1852. He entered at Queen's College, Cambridge, and in 1873 was appointed organist at Trinity College there. Except his operas, most of his works have been produced at one or other of the musical festivals in the provincial capitals of England—Gloucester, Birmingham, Leeds, Norwich, &c. His best and most successful productions have been the choral settings of Tennyson's *Reverence* (1886) and the *Voyage of Macduff* (1889); the oratorios *The Three Holy Children* (1885) and *Eden* (1891); the operas *The Veiled Prophet of Khorassan* (1881), *Savonarola* (1884), *The Canterbury Pilgrims* (1884), *Shamus O'Brien* (1896), *Much Ado About Nothing* (1901), *The Critic* (1916); an orchestral serenade; half-a-dozen symphonies, particularly the *Elegiac symphony* (1882); much chamber music; church music; and pieces for the violin and pianoforte. In 1882 he was appointed professor of Composition and Orchestral Playing in the Royal College of Music, and in 1887 succeeded Sir G. A. Macfarren as professor of Music at Cambridge. He wrote *Studies and Memories* (1908), *Musical Composition* (1911), and *Papers from an Unwritten Diary* (1914). He died 29th March 1924.

Stanford, LELAND, railway constructor, millionaire, and senator, was born at Waterbury, New York, 9th March 1824, and in 1856 settled in business in San Francisco. A strong supporter of the Pacific Railway scheme, he was made president of the Central Pacific Company, and superintended the construction of the line. Already governor of California, he was in 1885 elected a United States senator, and died in 1893. He and his widow founded and endowed the Leland Stanford Junior University at Palo Alto (q.v.), California, in memory of their son. This magnificent building was opened for students in 1891, but was partly ruined by the great earthquake of April 18, 1906.

Stangeria, a south-east African cycad, formerly mistaken for a fern, and hence named *S. paradoxa*. The stem is subterranean. There are usually one or two leaves, sometimes three or four, very fern-like. Balloons eagerly devour the seeds.

Stanhope, a town in the county of Durham, on the Wear, 26 miles W. of Durham by rail. Its rectory, once known in the north country as the 'golden rectory,' was held by Bishop Butler (1725-40). The famous lead-mines are now much less profitable than of old. Pop. 2000.

Stanhope, an earldom created in 1718 for JAMES STANHOPE (1675-1721), a grandson of the first Earl of Chesterfield, an eminent military commander, who effected the reduction of Mahón in Minorca, and was the favorite minister of George I.—His grandson, CHARLES, third earl (1753-1816), was an advanced Liberal, distinguished for his scientific researches, and the inventor of a printing press (see PRINTING, p. 388) which bears his name. See Life by Glitia Stanhope and G. P. Gooch (1914).—PHILIP HENRY, fifth Earl Stanhope, historian and

biographer, only son of the fourth earl, was born at Walmley, 31st January 1805. He took his B.A. at Oxford in 1827, and seven years later was created D.C.L., having entered the House of Commons in 1830. He was greatly instrumental in 1842 in securing the passing of the Copyright (q.v.) Act, was Under-secretary for Foreign Affairs during the brief Peel administration (1834-35), and Secretary to the Indian Board of Control under the same minister (1845-46). He was a moderate Conservative in politics, and was warmly attached to Sir Robert Peel, who named him one of his literary executors, and whose Memoirs he edited in conjunction with (Viscount) Cardwell. His contributions to history are numerous and valuable. Macaulay, in a review of his *War of the Succession in Spain* (1832), credits him with some of the most valuable qualities of a historian—viz. perspicuousness, conciseness, great diligence in examining authorities, great judgment in weighing testimony, and great impartiality in estimating characters. His most considerable work is *A History of England from the Peace of Utrecht to the Peace of Versailles, 1713-83* (7 vols. 1836-54); and his other works include *Lives of Belisarius, Condé* (originally in French), and *Pitt: a History of Spain under Charles II.*; an edition of *Lord Chesterfield's Letters; Historical and Critical Essays*; and *Miscellanies*. He was elected President of the Society of Antiquaries (1846), and Lord Rector of the university of Aberdeen (1858). He was known by the courtesy title of Viscount Mahon till 1855, when he succeeded his father in the earldom. He helped to secure the appointment of the Historical Manuscripts Commission and the foundation of the National Portrait Gallery. In 1872 he was elected one of the six foreign members of the Academy of Moral and Political Sciences at Paris, and he died at Boune-mouth, 22d December 1875.

Stanhope. See CHESTERFIELD.

Stanhope. LADY HESTER LUCY, the eldest daughter of Charles, third Earl Stanhope, and his wife Hester, daughter of the great Lord Chatham, was born at Chevening, Kent, on 12th March 1776. She grew up to be a woman of great personal charm and of unusual force and originality of character. In 1803 she went to reside with her uncle, William Pitt, and as mistress of his establishment and his most trusted confidant during his season of power and till his death she had full scope for the exercise of her imperious and queenly instincts. On Pitt's death in 1806 a pension of £1200 a year was assigned her by the king. Fox proposed to provide for her much more unbecomingly, but she proudly declined his offers, as unwilling to accept benefit at the hands of the political enemy of her dead uncle. The change from the excitements of a public career, as it might almost be called, to the life of an ordinary woman of her rank with means somewhat insufficient was naturally irksome to her, and in 1809 she was tried still further by the death at Coruña of her favourite brother Major Stanhope, and of Sir John Moore, for whom she is known to have cherished an affection. Conceiving a disgust for society, she retired for a time into Wales, and in 1810 left England, never to return. In mere restlessness of spirit she wandered on the eastern shores of the Mediterranean, and finally in 1814 settled herself among the half-savage tribes of Mount Lebanon. Here she led the strangest life, adopting in everything the Eastern manners, and by the force and fearlessness of her character obtaining a wonderful ascendancy over the rude races around her. She was regarded by them with superstitious reverence as a sort of prophetess, and gradually came so to consider herself. She indulged in political

intrigues, to the annoyance of British consuls. With the garb of a Mohammedan chieftain, she adopted something of the faith of one, and her religion, which seems to have been sincere and profound, was compounded in about equal proportions out of the Koran and the Bible. Her recklessly profuse liberalities involved her in constant straits for money; and her health also giving way, her last years were passed in wretchedness of various kinds, under which her untamable spirit supported her bravely to the end. She died on 23d June 1839, with no European near her.

Sources of information about her are the notes of Lamartine, Kinglake, and other travellers who visited her; the *Memoirs and Travels* derived from her own lips, and (1845-46) published by Dr Meryon, the physician who went abroad with her (boiled down by Mrs Roundell, 1909); a biography by 'Frank Hamel' (1913); and the *Life and Letters*, at first privately printed by her niece, the Duchess of Cleveland, and published in 1913.

Stanhopea, a genus of tropical American epiphytic orchids. The flowers are often large and scented, in hanging inflorescences, with elaborate floral mechanism, the labellum and column forming a sort of cage. The Mexican *S. tigrina* has flowers eight inches in diameter. It is believed that pollination is effected by insects entering the cage, finding their way on to a slippery surface, and sliding out at the mouth.

Stanburst. See STANYHURST.

Stanislaus. See LESZCZYŃSKI, POLAND, POŃIATOWSKI.

Stanisławów, or STANISLAU, a town in Eastern Galicia, stands on the Bistritza, 87 miles by rail S.E. of Lemberg, has important railway workshops, brick-works, &c., and is the seat of a Greek-Catholic (Ruthenian) bishop. Pop. (1921) 51,391, including many Jews. It was several times taken and retaken in the Great War.

Stanko. See COS.

Stanley, capital of the Falklands Islands, on Stanley Harbour, on the east coast of East Falkland, was founded as a port of refuge; pop. 1000.

Stanley. (1) a coal-mining town of Durham, 8 miles W. of Durham; pop. 25,000. (2) A town of the West Riding of Yorkshire, 2 miles N.N.E. of Wakefield; pop. 15,000.—(3) A village 7 miles N.W. of Perth.

Stanley. See DERBY (EARL OF).

Stanley, ARTHUR PENRHYN, born at Alderley rectory, Cheshire, 13th December 1815, was the second son of Edward Stanley (1779-1849), from 1837 Bishop of Norwich. Educated at Rugby under Arnold, and at Balliol, he won the Ireland and the Newdigate, and graduated with a first-class in 1837. In 1839 he was elected a fellow of University College and took orders. In 1840 he travelled in the East, during 1841-51 was a college tutor, and in 1851 became a canon of Canterbury, in 1856 professor of Ecclesiastical History and canon of Christ Church, and in 1863 Dean of Westminster. A voluminous writer in the periodical press, he was author of the *Life of Arnold* (1844), *Sermons on the Apostolic Age* (1847), *Memoir of Bishop Stanley* (1851), *Commentary on Corinthians* (1855), *Memorials of Canterbury* (1855), *Sinai and Palestine* (1856), *Memorials of Cambridge* (1857), *Lectures on the Eastern Church* (1861), *Lectures on the Jewish Church* (1863-65), *Memorials of Westminster Abbey* (1868), *Essays on Church and State* (1870), *Lectures on the Scottish Church* (1872), *Addresses and Sermons delivered at St Andrews* (1877: he was elected Lord Rector, 1874), *Memorials of Edward and Catherine Stanley* (1879), and *Christian Institutions* (1881). Outstanding events in his life were his travels in Egypt and

Palestine (1852-53), and in Russia (1857); his accompanying the Prince of Wales on his Eastern tour (1862); his marriage (1863) to Lady Augusta Bruce (1822-76), of the Elgin family; a second visit to Russia (1874), when he celebrated the English marriage of the Duke and Duchess of Edinburgh; and his visit to America (1878). For all his large tolerance, charity, and sympathy, High Church Anglicans could never forgive him for championing Colenso and for preaching in Scottish Presbyterian pulpits. He was pre-eminently representative of the broadest theology of the Church of England. Christianity to him was sacred because of its moral and spiritual elements, and the divinely perfect life embodying these; but for systematic theology he had little reverence, and none at all for the pretensions of the priesthood; whilst he regarded as 'infinitely little' the controversies about postures, fights, vestments, and the like. The Evangelicals also deplored his lack of 'the root of the matter.' As a preacher he wielded a wide influence. His ancient lineage, his independent and exalted ecclesiastical office, his personal popularity, his alliance with a lady of mental ability and social charm, all combined to invest the Deanery with singular prestige and influence as a centre of society. He died 18th July 1881, and was buried by the Queen's commands beside his wife in Henry VII.'s Chapel. See Life by R. E. Prothero (Lord Ernle) and Dean Bradley (1891); *Letters and Verses*, edited by Prothero (1895); and *Recollections of A. P. Stanley*, by Dean Bradley (1883).

Stanley, Sir Henry Morton, G.C.B. (created 1899), the African explorer, was born at Denbigh, in Wales, in 1841. His parents were not married; his father died soon after, and his unloving mother left the child to her father's care. When old Moses Parry died in 1847, John Rowlands, as Stanley was then called, was sent to St. Asaph workhouse. After a hard, unhappy boyhood, he shipped in 1850 for New Orleans, where he was fortunate enough to win the sympathy of a broker named Stanley. He assumed the name of his benefactor; but on the death of Mr Stanley intestate in 1861, he was again thrown on his own resources. He served in the Confederate army, and was taken prisoner at the battle of Shiloh (1862). After further adventures Stanley joined the U.S. navy, serving as ship's writer till 1865, when he drifted into journalism. In 1867 he was acting as correspondent for the *New York Tribune* and the *Missouri Democrat* on a military expedition against the Indians, and towards the close of that year began his connection with the *New York Herald*. It was as its special correspondent that Stanley first entered Africa. He accompanied Lord Napier's Abyssinian expedition, and so ably did he make his dispositions that the first news of the fall of Magdala was conveyed to the British public—and also to the British government—by the *New York Herald*. Stanley next went to Spain for his paper, and while in Madrid received the famous telegram from Mr Gordon Bennett summoning him to Paris; he went at once, and received the laconic instruction 'Find Livingstone.' This was in October 1869, but Stanley did not at once proceed on his new mission; he visited Egypt for the opening of the Suez Canal, and travelled through Palestine, Turkey, southern Russia, and Persia, arriving in India in August 1870. In the following January he reached Zanzibar, and towards the end of March he set out on his first expedition into the heart of the dark continent. One white companion died; the other proved 'a mere burden'; there was the usual trouble with porters; but Stanley displayed qualities of courage, perseverance, and command over the native African which won for him

a high position in the long roll of African explorers. The road to Tanganyika was not then what it is now; but all difficulties were overcome, and on November 10th Stanley had the satisfaction of greeting Livingstone. For four months they remained together, and there can be little doubt that the influence and example of Livingstone during these four months had a lasting effect on Stanley's character and career. Stanley met Livingstone a special correspondent; he parted from Livingstone with the fever of African exploration burning in his veins. The two men had together explored the north end of Lake Tanganyika, and conclusively settled that the lake had no connection with the Nile basin. On March 14, 1872, Stanley left Livingstone and set out on his return to the coast, having left large quantities of goods with the veteran, and given promises of further assistance. In less than two months he arrived at Zanzibar, and in August in England, where he was awarded the medal of the Royal Geographical Society, and feted as the lion of the hour. His book, *How I Found Livingstone*, had an enormous sale. During the Ashanti campaign he followed the fortunes of Wolseley's troops, for the *New York Herald*, and he returned to London only just in time to assist at the funeral of Livingstone in Westminster Abbey. The news of Livingstone's death kindled in Stanley a great resolution to complete the work in which his master had lost his life.

An expedition fitted out at the joint charge of the *New York Herald* and the *Daily Telegraph* was projected, with Stanley in supreme command. In August 1874 he left England to attempt the solution of some of the great problems of Central African geography. In November, with some 350 men of all descriptions, he quitted Bagamoyo, following the ordinary route to Ugogo, when, turning suddenly northwards, he made for the southern shore of the Victoria Nyanza. From Kagehi, on Speke Gulf, he circumnavigated the lake, and approximately fixed its general outline. In Uganda he formed a close friendship with King Mtesa, and on his return home his reports of the readiness of the king to receive instruction in the Christian religion led to a great outburst of missionary enthusiasm, and the establishment of mission stations in Uganda. At Dambichen, an island off the south-west shore of the lake, he came into serious conflict with the natives, and the severe measures he adopted on this and other occasions aroused much hostile criticism in England. Passing through Kagarwé, he reached Tanganyika, and set himself to determine its exact configuration. This accomplished, he made his way to Nyangwé on the Lualaba, where he first met Tippu Tib, the Arab chief; and from Tippu he learned that Cameron had not attempted the solution of the problem suggested by this great mass of water flowing northwards. It is of course impossible to give even in the barest outline the story of Stanley's ten months' journey from Nyangwé to the sea, by which he traced the course of the Congo and filled up an enormous blank in the map of Africa. When he arrived at Boma (9th August 1877) all his white companions were dead, hardly a third of his native followers had survived, and Stanley's black man had turned white. It would be difficult to exaggerate the effect produced by this great journey. Politically it led directly to the founding of the Congo Free State (now Belgian Congo), and indirectly to that scramble for Africa among the European powers which left but an insignificant portion of the continent unpartitioned. Stanley returned to London in January 1878, published *Through the Dark Continent*, and in 1879 again went out to Africa to found, under the auspices of Leopold II. of Belgium,

the Congo Free State. Until 1884 this work engaged all his energies. He then returned to Europe, and in 1885 published *The Congo and the Founding of its Free State*. He took part in the Congo Congress at Berlin in 1884-85, and lectured widely, in Britain and in America, on his African work.

Towards the end of 1886 Stanley was summoned from America to take command of the expedition for the relief of Emin Pasha (see SCHNITZER). On 22d February 1887 he arrived at Zanzibar; on the 25th he, his officers, and the Zanzibari porters, Somalis, and Sudanese soldiers sailed for the mouth of the Congo, where they landed on 18th March. On 15th June the expedition had reached the village of Yambuya, 1400 miles from the sea, on the left bank of the Aruwimi, 96 miles above its confluence with the Congo. Here Stanley divided his forces. He left at Yambuya camp a large number of loads, which were to be brought on as soon as porters were provided by Tippu Tib. The entire force which left Zanzibar numbered, all told, 706 men. Between Zanzibar and Yambuya it was reduced to 649. Of this number 389, including Stanley and four Europeans, made up the advance force. Major Bartleot was left in command of the rear column, and on 28th June Stanley set out on his forced march through the forest. It is impossible to follow in detail the story of Stanley's indomitable struggle with almost insurmountable difficulties. Not till the end of April 1888 did Emin and Stanley join hands on the shores of the Albert Nyanza. Retracing his steps, Stanley found that disaster had overtaken his followers left behind at Yambuya. With amazing fortitude he reorganised his party and again joined Emin on Albert Nyanza. The return journey was made by an overland route to the east coast, and Bagamoyo was reached on 4th December 1889. Apart from the main object of this expedition, Stanley discovered Albert Edward Nyanza and the lofty snow-capped mountains of the Moon (Ruwenzori range), and established the existence of a vast pigmy-inhabited tropical forest to the west of the lake country, and occupying the northern portion of the Congo basin. This journey also led to the foundation of the British East African Protectorate. In 1890 Stanley, after reuniting his health in Egypt, returned to London, and met with a royal reception. He married Miss Dorothy Tennant (1890), abandoned American for British citizenship, settled in England, stood unsuccessfully as Unionist candidate for North Lambeth in 1892, was elected in 1895, sat—without attaining parliamentary distinction—till 1900. His health undermined by his African travels, he died 9th May 1904. His tombstone records the significant name given him by the Congo natives—*Bula Matari*, Breaker of Rocks—i.e. Maker of Roads.

His works include, besides those named above, *Cook-masse and Mayinda* (1874); *In Darked Africa: or the Quest, Rescue, and Retreat of Emin* (1890); a tale, *My Kibuka* (1873); *My Dark Companions and their Strange Stories* (1893); *My Early Travels in America and Asia* (1895); and *Through South Africa* (1898). See his *Autobiography* (1909), edited and completed by his wife, an accomplished artist, who afterwards married Dr H. Curtis, and died in 1926; and the articles SCHNITZER, CONGO.

Stanley, THOMAS, son of Sir Thomas Stanley, was born at his house of Gumberlow, in Hertfordshire in 1625. He had Fairfax, translator of Tasso, for private tutor, and studied at Cambridge, passing M.A. in 1641. He also had the Oxford master's degree, though he does not seem to have studied there. He became a member of the Middle Temple, and practised law throughout life, though his best energies were given to literature. He published translations from the Greek, Latin, French, Spanish, and Italian poets;

but his great works were the *History of Philosophy* (4 vols. 1655-62) and an edition of Æschylus, with Latin translation and commentary (1663-64). The former deals only with Greek philosophy, and is based on Diogenes Laertius; but it was long a standard work, having been translated into Latin by Leclerc and others. The Æschylus was generally considered to surpass its predecessors (though Stanley was blamed for 'plagiarism' from Casaubon, Scaliger, and others); the best edition is Butler's (1809-16). Stanley died in London, 12th April 1678. See Brydges' edition of his *Poems* (1814-15), Saintsbury's (in *Caroline Minor Poets*, vol. iii. 1922), and Miss Guiney's of his *Original Lyrics* (1907).

Stanley, VENETIA. See DIGBY (KENELM).

Stanley Falls, Stanleyville. See CONGO.

Stanley Pool. a lake-like expansion of the river Congo about 350 miles from its mouth, discovered by Stanley in 1877. It measures 25 miles by 16, and lies 1142 feet above sea-level. It is connected by railway with Matadi (see CONGO).

Stannaries (Lat. *stannum*, 'tin'), the mines from which tin is dug. The term is most generally used with reference to the peculiar laws and usages of the tin-mines in the counties of Cornwall and Devon. By an early usage peculiar to these counties, the prerogative of the crown, elsewhere reaching only to gold and silver mines, is extended to mines of tin, which are the property of the sovereign, whoever be the owner of the soil. A charter of King John to his tinnets in Cornwall and Devonshire, of date 1201, authorised them to dig tin, and tuit to melt the tin, anywhere in the moors, and in the fees of bishops, abbots, and earls, as they had been used and accustomed—a privilege afterwards confirmed by successive monarchs. When Edward III. created his son, the Black Prince, Duke of Cornwall, he at the same time conferred on him the Stannaries of Devon and Cornwall, which were incorporated in perpetuity with the duchy. Their administration is committed to an officer called the Lord Warden of the Stannaries, who has two substitutes or vice-wardens, one for Cornwall and one for Devon. In former times representative assemblies of the tinnets (called parliaments) were summoned by the warden, under a writ from the Duke of Cornwall, for the regulation of the stannaries and redress of grievances: the last of them was held in 1752. The Stannary Courts are courts of record held by the warden and vice-warden, of the same limited and exclusive character as the Courts palatine, in which the tinnets have the privilege of suing and being sued. They were remodelled and regulated by a series of acts of parliament. Appeals from these courts are now taken to the Court of Appeal, and there is a final appeal to the House of Lords. In Cornwall the right to dig tin in unenclosed or 'wastrel' lands within specified bounds may be acquired by one who is not the owner of the lands, on going through certain formalities, the party acquiring this right being bound to pay one-fifth of the value of the lands. An ancient privilege, by which the Duke of Cornwall had the right of pre-emption of tin throughout that county, has long fallen into abeyance.

Stannovoi Mountains. See SIBERIA.

Stanton Drew, a small village of Somersetshire, 7 miles S. of Bristol, with great megalithic remains, especially stone circles.

Stanyhurst, RICHARD (1547-1618), born at Dublin, studied at Oxford, and died a Catholic priest at Brussels. He wrote on Irish history,

commented on Porphyry, and translated part of Virgil and some Psalms into hexameters of the Gabriel Harvey kind. See HOLINSHEAD.

Stapelia. See CARRION FLOWERS.

Stapes, a stirrup-shaped bone of the Ear (q.v.).

Staphylea. See BLADDER-NUT.

Staphyleaceæ, a family of archichlamydeous dicotyledons, trees and shrubs, akin to Celastraceæ, mainly inhabitants of the Northern Hemisphere. The flowers are regular, with five sepals, five petals, five stamens, and a superior trilocular ovary of three carpels. The fruit is a capsule (see BLADDER-NUT). The axis is concave, and forms a disc within the ring of stamens. The leaves are imparipinnate (rarely simple), stipulate. In Staphylea, Turpinea, and Euscaphia they are opposite, in Tapiscia and Hueterea alternate.

Staple, a word representing both Old English *stapol* and Old French *estaple*, which, borrowed through mediæval Latin *stapola*, from Low German, is ultimately of the same origin as the Old English word. The history of the many meanings is obscure. Probably the Old Teutonic word meant a support; hence it came to mean a post, platform, heap, &c. Perhaps from the last-mentioned it came to mean a place where goods are stored up for sale. Or possibly the 'king's staple' was originally a raised platform from which judgment was administered. In the middle ages, when the term was in common use, a staple meant both the trading-town for particular commodities and the commodities that were wont to be exposed for sale there. The kings of England from the beginning of the 14th century issued various regulations affecting the staple towns for the sale of England's principal commodity in those ages—wool. In 1313 Edward II. enjoined that all English merchants trading abroad, in Flanders, Brabant, and the adjacent countries, should carry all their wool to one staple town in Flanders; from 1343 Bruges was the town that enjoyed this privilege. But the men of Bruges greatly hampered the trade, and put vexatious hindrances in the way of the English merchants trading with the towns that lay farther inland; so that in 1353 Edward III. transferred the staple to England, and shared its privileges amongst half a score of coast towns from Newcastle to Bristol. At the same time all questions in dispute affecting mercantile transactions at these towns were put under the jurisdiction of an officer (one in each town) called the mayor of the staple, who decided all such differences by 'merchant law,' with the assistance of foreign merchants as assessors. The change to England, however, which it was hoped would relieve the English merchant from the vexatious interference of foreign governments and advantage the island country by attracting foreign merchants, proved anything but satisfactory, and from about the year 1362 the staple for English wool was almost constantly fixed at Calais, and remained there down to the year 1558. The Scottish merchants had their staple at Campvere (q.v.) in Holland. But as commerce grew with the lapse of time, it gradually broke down the barriers imposed by the system of staples. This concentration of trade in particular commodities or of particular countries at certain cities and towns was owing to both economic and political reasons. It was a sort of established policy of the Plantagenet kings to regulate trade in the interests of the royal power. Important privileges were accorded to foreign merchants on condition of their agreeing to frequent certain towns for purposes of traffic. This, too, enabled the royal officers of the customs the more readily and easily to collect the revenues of the crown accruing from those sources. And this line of state policy was so far congruent with

the requirements of international commerce that it was the means of bringing buyers and sellers together at the same time and in the same place, and that it enabled the merchants trading from or to one town, or country, or association of trading-towns, to combine together for their mutual advantage and protection.

Stapes. See FARNE.

Stapleton-Cotton. See COMBERMERE.

Star. See STARS, ORDERS OF KNIGHTHOOD.

Star-Anise. See ANISE.

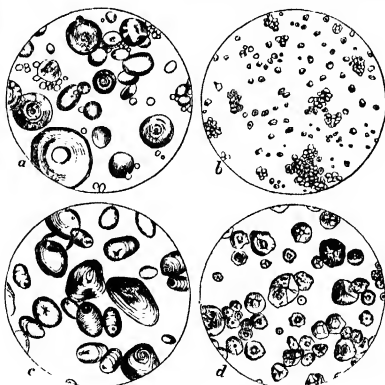

Star Apple (*Chrysophyllum*), a genus of trees and shrubs of the family Sapotaceæ. They are natives of tropical and subtropical countries. The Star Apple of the West Indies (*C. Caimito*) is a tree about 30 or 40 feet high. The fruit is large, purple or green, and has a soft sweet pulp of an agreeable flavour. Other species also produce edible fruit.

Staraya-Russa, a town of Russia, 62 miles S. of Novgorod by rail round Lake Ilmen, is remarkable for its salt springs.

Stara-Zagora (Turkish *Eski-Zagora*), a town of Bulgaria at the southern base of the Balkans, 70 miles NNW. of Adrianople, was almost destroyed during the Russo-Turkish war of 1877-78; pop. 25,000.

Starboard. See STEERING.

Starch. $C_6H_{10}O_5$. It is one of the essential functions of the leaves of plants to decompose carbon dioxide, by the help of sunlight which shines through the chlorophyll, with evolution of oxygen and the formation of starch. The starch becomes converted by a diastatic ferment into sugar, which passes from the leaves to various parts of the plants, and being reconverted into starch, is stored. See CHLOROPHYLL, LEAF, and SEED. It is in this way that fruits and seeds, stems—e.g. that of the sago palm, tubers like the potato—tap-roots, bulbs, &c. become stored with starch. The granules of starch are usually of a rounded form, consisting of a nucleus surrounded by a number of envelopes or layers. Each species of plant has its own peculiar

Starch Granules:

a, wheat; b, rice; c, potato; d, maize; all magnified 250 diameters. (From Dr Bell's *Chemistry of Food*.)

shape of granule which can be recognised under the microscope, but in the same plant these granules differ in size. The smallest size of a granule of oat-starch is '0001, while the largest-sized granule of Tous-les-mois starch is about '0015 of an inch.

Starch has the same elementary composition as sugar, gum, and cellulose. These all belong to a class of substances called *carbohydrates*, because they could be represented as compounds of carbon and water, as shown by the formula given above, which corresponds to six atoms of carbon and five molecules of water, H_2O . Starch contains no nitrogen, and is thus distinguished from characteristic animal compounds. The peculiar structure of starch granules and the way in which they occur in the vegetable cell permit of their being readily separated from other matters occurring along with them in plants. As usually prepared, starch is either a white glistening powder or it is obtained in irregular prisms which arise from the cracking up of a cake of the dried material. When pressed between the fingers a slight but peculiar sound is produced. Its specific gravity varies from 1.55 to 1.60. Starch is soluble only to a very slight extent in cold water, but when heated in water to above 150° F. the granules burst, and a clearropy solution is formed which, on cooling, becomes a translucent jelly called starch-paste. This paste gives a deep-blue colour with iodine and an orange-yellow with bromine, the former being a highly characteristic and delicate test for starch. If a salt of iodine, such as iodide of potassium, is used, the iodine must be liberated either by a drop of strong nitric acid or preferably by a little chlorine water. By the gentle action of nitric acid on starch an explosive compound called *xyloidine* is obtained. At a temperature of about 320° F. (160° C.) starch is converted into *dextrine* or *British gum*, and the same change is produced on starch by the action of dilute mineral acids. Dextrine is usually made on an industrial scale from potato-starch. It is this Dextrine (q.v.) which is the adhesive matter on postage-stamps, but it is otherwise largely used in the arts. By the further action of acids on starch *dextrose* or grape-sugar, and also the crystallisable sugar, *maltose*, are obtained. Maltose sugar is likewise produced during the operation of malting by the action of diastase on the starch of grain.

Starch is heard of in England as early as 1511, or even sixty or seventy years earlier, but was not much used till 1564, when, according to Planché, 'Mistress Bingham Vaudh Plasse, a Fleming, came to London, and publicly taught the art of starching. . . . Stubbes falls foul of this "liquid matter which they call starch, wherein the devil hath learned them to wash and dive their ruffs, which being dry will then stand stiff and inflexible about their necks."' Not only ruffs but beads were starched. Later yellow starch, introduced by Anne Turner, had a great vogue, which suddenly ended when Mrs Turner was hanged in yellow-starched ruff for complicity in the murder of Sir Thomas Overbury (q.v.).

Manufacture.—Starch is manufactured on a large scale in Europe from maize, wheat, rice, potatoes, and from sago flour.

Maize-starch.—Maize contains 65 per cent. of starch and about 14 of gluten and other nitrogenous matters. The grain is first steeped for forty-eight hours in water at a temperature not exceeding 120° F. It is then ground with water by millstones into a milky state, after which it is sieved to keep back the husks. From the sieve the starchy liquid passes into 'runs' or channels made of wood, from 2½ to 4 feet broad and 9 inches deep, in which the starch deposits. It is then removed from the runs and put along with water into vats or tuns (10 feet in diameter and 4 feet 6 inches deep) provided with stirrers, some very weak soda-lye being added. After it is sufficiently stirred the liquid is allowed to settle, when the starch falls to the bottom. At this stage the vats contain a layer of starch, over it a layer

of gluten, and above that again a stratum of yellowish water thick with gluten. The starch is again washed with water in the final settling vats, from which, after drawing off the water, it is removed and spread on clean cotton sheeting to be dried in stoves at a temperature between 120° and 130° F. A little bleaching powder is used to bleach maize and other kinds of starch.

Potato-starch.—In manufacturing starch from potatoes, the latter are first washed in machines of various kinds, of which one of the simplest is a revolving cage-like cylinder with wooden bars. Then follows the grating of the washed potatoes by forcing them against the saw-like teeth of rasps, which, as sufficient water is fed to the machine, reduces them to a paste. In order to separate fibrous and albuminous matters and other impurities, the starch-paste with an addition of water is passed through fine sieves, and at the same time agitated by various arrangements. From the sieves it is received into settling tanks in which the deposit of starch is again washed in clean water. It then descends in a milky stream over an inclined plane, on which the starch is deposited, and afterwards once more washed. A little alum or sulphuric acid is used to assist in the removal of albuminous matters. The starch is dried either on porous bricks or on slabs of gypsum, and for some purposes it undergoes another drying in a hot chamber.

Wheat-starch.—Owing to the huge amount of albuminous and other nitrogenous bodies (gluten or its equivalents) which wheat contains, amounting sometimes to more than 15 per cent., the methods of making starch from this grain are a little more complicated than the processes employed to obtain it from other cereals or potatoes. Wheat-starch is made by the old plan of removing the gluten by fermentation, and also by Martin's method of kneading the flour into a stiff dough and washing out the starch with water on a sieve. Good English wheat contains about 69 per cent. of starch, but in this grain the proportion of both starch and gluten varies much.

Rice starch is prepared by removing the gluten, which amounts to from 7 to 8 per cent. of the seed, by the action of soda in weak solution. The proportion of starch in rice is higher than it is in other cereals, varying from a little under to a little over 80 per cent. The *corn-flours* of commerce are prepared either from the purified starch of maize or from that of rice. These flours, being nearly pure starches, with the flesh and bone forming constituents extracted, are not flours of their respective seeds in the sense that wheat-flour is.

Sago-starch is obtained from the path of the stems of sago palms (see PALM and SAGO). Most of the sago imported into England is in the form of sago-flour, which is used in the manufacture of household starch and glucose sugar. Besides its use in the laundry, starch is extensively employed in dressing textile fabrics and as a thickener for the colours used in printing calico; also for mounting photographic prints and dusting foundries' moulds.

The principal starches prepared for food besides the 'corn-flours' are *Arrowroot* (q.v.), *Tapioca* (q.v.); and *Tous-les-mois*, from the rhizomes of a species of *Canna* cultivated in St Kitts, West Indies. *Curcuma Starch* is made to some extent in southern India from the tuberous root of *Curcuma angustifolia*, and is sometimes called by Europeans East India arrowroot. In France starch is manufactured from horse-chestnuts. Paisley is the principal seat of the starch-manufacture in Great Britain, where it is chiefly made from maize. Rice-starch is made on a large scale at Norwich, and wheat-starch at Belfast.

In the United States, where maize-starch was

first produced in 1842, the principal manufactories are at Oswego, New York, and at Glen Cove, on Long Island. Maize-starch is manufactured from a large porous-grained Indian corn.

It was discovered in 1912 that synthetic rubber could be prepared from starch. By a process of fermentation butyl alcohol is got from the starch. It is then converted into the hydrocarbon isoprene, which polymerises to rubber in contact with sodium.

Star-chamber, a tribunal which met in the old Council-chamber of the palace of Westminster, and is said to have got its name from the roof of that apartment being decorated with gilt stars. That 'starres' or Jewish bonds had been kept in it is not now believed. It is supposed to have originated in early times out of the exercise of jurisdiction by the king's council, whose powers in this respect had greatly declined when in 1487 Henry VII., anxious to repress the indolence and illegal exactions of powerful landowners, revived and remodelled them, or, according to some investigators, instituted what was practically an entirely new tribunal. The statute conferred on the Chancellor, the Treasurer, and the Keeper of the Privy Seal, with the assistance of a bishop and a temporal Lord of the Council, and Chief Justices, or two other justices in their absence, a jurisdiction to punish, without a jury, the misdemeanours of sheriffs and juries, as well as riots and unlawful assemblies. Henry VIII. added to the other members of the court the President of the Council, and ultimately all the privy-councillors were members of it. The resulting tribunal was, during the Tudor age, of undoubted utility as a means of bringing to justice great and powerful offenders who would otherwise have had it in their power to set the law at defiance. It was independent of a jury, and at that time juries were too easily terrified by the nobles. The civil jurisdiction of the Star-chamber comprised controversies between English and foreign merchants, testamentary causes, disputes between the heads and commonalty of corporations, lay and ecclesiastical, and claims to deadlands. As a criminal court it could inflict any punishment short of death, and had cognisance of forgery, perjury, riots, maintenance, fraud, libels, conspiracy, misconduct of judges and others connected with the administration of the law, and all offences against the state, in so far as they could be brought under the denomination of contempt of the king's authority. Even treason, murder, and felony could be brought under the jurisdiction of the Star-chamber, where the king chose to remit the capital sentence. The form of proceeding was by written information and interrogatories, except when the accused person confessed, in which case the information and proceedings were oral; and out of this exception grew one of the most flagrant abuses of this tribunal in the later period of its history. Regardless of the existing rule that the confession must be free and unconstrained, pressure of every kind, including torture, was used to procure acknowledgments of guilt; admissions of the most immaterial facts were construed into confessions; and fine, imprisonment, and mutilation inflicted on a mere oral proceeding, without hearing the accused, by a court consisting of the immediate representatives of prerogative. The proceedings of the Star-chamber had always been viewed with distrust by the commons; but during the reign of Charles I. its excesses reached a pitch that made it odious to the country, especially the punishments inflicted on Leighton, Prynne, Burton, and Bastwick; and in 1641 a bill carried in both Houses decreed the abolition of the Star-chamber and the equally unpopular court of High Commission (q.v.). See CHARLES I., LAUD.

See Leadam's *Select Cases before the King's Council of the Star Chamber* (Selden Society, 1904).

Starch-hyacinth. See GRAPE-HYACINTH.

Starfishes (Asteroidea), a class of Echinoderms, nearly allied to the Brittle-stars (Ophiuroidea) and to the Sea-urchins (Echinoidea). The Common Five-rayed Starfish (*Asterias* or *Asteracanthion rubens*) is sometimes seen in shore-pools about the low-water level, but its haunts are on the floor of the sea at depths of a few fathoms. It moves sluggishly by means of suckorial tube-feet on the under surface of each arm. It often feeds on young oysters and other bivalves, but it may live on much smaller booty. Although without any

Fig. 1.—Starfishes and Brittle-stars:

Common Starfish (*Asterias rubens*); 2, Gibbous Starlet (*Asterina gibbosa*); 3, Common Starfish, reproducing rays; 4, Eved Crinella (*Crinella oculata*); 5, Lesser Sand-star (*Ophiura albida*). (From Forbes's *British Starfishes*)

concentration of nerve-cells into ganglia, the starfish often exhibits genuine behaviour. Thus it will attack a small sea-urchin and gradually wrench off the snapping spines or pedicellariae which fasten on to its suckorial tube-feet, continuing to do so until the sea-urchin has no weapons left. Jennings has shown that a starfish is able to form habits and to profit by its experience. When it is in process of righting itself after being turned upside-down 'given parts sacrifice their own more direct turning, or even reverse it, in the interest of

Fig. 2.—Longitudinal Section of an Arm:

Section through arm and disk of *Solaster*, showing (a) mouth, (b) stomach, (c) digestive caeca, (d) reproductive organs, (e), madreporic plate, (f) stone canal, (g) tube-foot.

the general result.' There is a harmonious working together of the different parts under the action of the righting impulse, and experiment shows that one factor in this correlation is previous experience. For some time the starfish rights itself in awkward ways, certain rays playing a part that hinders rather than helps the process. But gradually it learns to right itself more effectively.

Although a typical starfish appears very different from a sea-urchin, there is a close homology of

parts. As regards shape, the dorsal surface of a starfish corresponds with the anal area or 'periproct' in the centre of the apical disc of a sea-urchin, the ventral surface with the ambulacral grooves to the ambulacral areas, and the sides of the arms to the inter-ambulacral areas. The tips of the arms of the starfish each with an eye-spot—a modified tentacle—correspond to the 'ocular plates' around the periproct of the sea-urchin. Through these plates in the common sea-urchin (*Echinus esculentus*) five sensitive tube-feet emerge. The five genital plates of the sea-urchin's apical disc correspond to the corners between the arms of the starfish.

Like most Echinoderms, the starfish is very calcareous. Forming the ventral groove of each arm there are important rafter-like plates called ambulacral ossicles; from the more external mesoderm are developed smaller ossicles, superficial spines, and snapping scissor-like pedicellariæ. The starfish is not very muscular, but the arms can be bent in various ways, part of the stomach can be protruded, and there are contractile elements in connection with the water-vascular system. Besides the five radial nerves and the circum-oral pentagon, there is a diffuse nervous network beneath the ciliated ectoderm covering the body. Thus the skin is diffusely sensitive, and the little red 'eye' at the tip of each arm is certainly sensitive to light. The mouth is in the centre of the ventral surface; from the median stomach a pair of digestive ceca grow out into each arm; from the short tubular intestine between the stomach and the central dorsal anus, two little outgrowths arise, comparable, it is said, to the respiratory trees of Holothurians. There is a distinct, though not spacious, body-cavity, lined by ciliated epithelium, and containing a fluid with some amoeboid cells, the brownish pigment of which perhaps aids in respiration.

When we watch a starfish crawling up the side of a rock we see that scores of soft tube-feet are protruded from the ventral groove of each arm, that these become long and tense, and that their sucker-like terminal discs are pressed against the hard surface. There they are fixed, and towards the attachment the starfish gently lifts itself. The protrusion is effected by the internal injection of fluid into the tube-feet; the fixing is due to the fact that the contained fluid, flowing back again from the tube-feet to the internal reservoirs, produces a vacuum between the ends of the tube-feet and the surface of the rock.

On the dorsal surface, between the bases of two of the arms, there is a complex calcareous sieve, somewhat suggestive of the rose of a watering-pot. Its pores converge into a 'stone-can', which, like a complex calcareous filter, extends vertically through the body, and leads into a ring around the mouth. This circum-oral ring gives off nine transparent vesicles and five radial tubes, one for each arm. Each radial vessel lies in the ventral groove of an arm, roofed by the rafter-like ossicles, and gives off internally reservoir-like bladders or ampullæ, and externally the tube-feet. The fluid in the system seems to pass from the radial vessels into the tube-feet, and from the tube-feet back into the ampullæ. It is evident

Fig. 3.—Bipinnaria with young Starfish developing within it.

end of each arm there is a long unpaired tube-foot which acts like a tactile tentacle. There are various channels and sinuses which have been called blood-vessels, but a true vascular system seems to be absent. Respiration is in great part discharged by numerous 'skin-gills,' contractile hollow outgrowths from the skin of the dorsal and lateral surfaces. Of excretion in the starfish we know almost nothing. The sexes are separate, but quite like one another; the reproductive organs—branched like elongated bunches of grapes—lie in pairs in each arm; the genital ducts open dorsally between the bases of the arms.

The ova are fertilised in the water. It is said that they occasionally begin to develop without fertilisation. The segmentation is complete; a blastosphere is formed and a typical gastrula. The free-swimming larva, as in other Echinoderms, is remarkably specialised, with two ciliated bands and peculiar arm-like outgrowths. It is known as a Bipinnaria or as a Brachiolaria. The adult is a new formation within the larva, retaining the water-vascular system, and midgut, but absorbing or rejecting the provisional larval structures. There is also in this indirect development a remarkable change from bilateral to radial symmetry. Parental care occasionally occurs among Asteroids; thus a large *Asterias* has been seen sheltering its young within its arms, while in *Pteraster* and some others there is a dorsal brood-pouch. Many Asteroids break very readily, throwing off then arms when seized. The lost parts are slowly regenerated, and strange shapes, especially the 'comet form,' often result in the course of regrowth. This 'autotomy' of members may sometimes be a means of multiplication, as in *Lucinia guldenquai*.

The commonest European starfishes are species of *Asterias* or *Asteracanthion*, *Astropecten*, *Cribrella*, *Solaster*, *Goniaster*. In *Astropecten* and several related forms the food-canal ends blindly; in *Beringa* the arms are very long and arise abruptly from a small central disc, as in Ophiroids; in *Lucinia* the pedicellariæ are three-bladed instead of two-bladed; and there are many minor differences like the above. There are also considerable differences in external form; witness the many-rayed *Solaster*, the pin-cushion-like *Goniaster*, the flat pentagonal *Palmipes*. The largest forms are such as *Asterias*

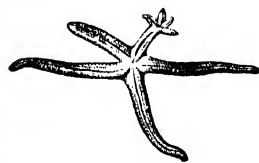

Fig. 4.—Process of budding from one of the arms of *Lucinia guldenquai*. (After P. and F. Sarasin.)

gigantea, from the Pacific coast of North America, which measures two feet in diameter, and *Pycnopodia helianthoides*, which measures about a yard in diameter, and has over twenty arms. The majority live in comparatively shallow water, but the Ophiroid-like *Beringa*, the widely distributed *Hymenaster*, the blue *Porcellanaster ceruleus*, and many others are deep-sea forms. The earliest occurrence of Asteroids is in Silurian strata.

The Brittle-stars (Ophiuroidea) differ from Asteroids in the more centralised body, more sharply defined arms, and more active habit. Compared more fully with starfishes, the brittle-stars are more muscular and less limy; the arms do not contain digestive ceca from the gut nor reproductive organs, and are supported by an axis of limy 'vertebral ossicles'; the tube-feet are smaller, apparently tactile and respiratory, and locomotion is effected by the muscular wriggling of the arms;

that the water-vascular system is modified for locomotion, but it is likely that it also helps in respiration and perhaps also in excretion. At the

the groove so well seen on the ventral surface of the starfish arm is here closed in by limy plates; the alimentary canal ends blindly; the entrance to the water-vascular system (madreporic plate) is ventral; the larval form is known as a *Pluteus*. The popular name 'brittle-star' refers to the extreme ease with which the arms break; another common name, 'sand-stars', refers less happily to their occasional occurrence on the shore; the technical title *Ophiuroid* describes the snake-like coils of their arms.

The brittle-stars creep about by wriggling their unsclerous arms. Some are found creeping on the shores at low-tide, but the majority keep to the floor of more or less deep water. On blocks of

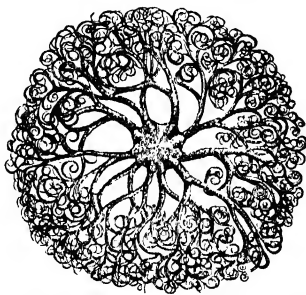

Fig. 5.—The Shetland Argus (*Astrophyton scintillans*). (From Forbes)

coral and the like they swarm in enormous numbers, twisting themselves most fantastically about the crevices. They are voracious animals feeding on small molluscs, crustaceans, worms, and much simpler organisms like *Potamifera*.

With few exceptions (e.g. *Amphura squamata*), the brittle stars are unisexual. In most the eggs are liberated as such, are fertilised externally, and develop in the water; but some species—e.g. *Ophiopholis bellis*, *Ophiocoma viripara*—produce their young alive (viviparously), and in these cases

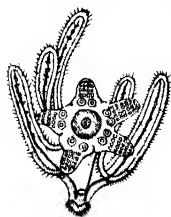

Fig. 6.—*Pluteus* larva with young *Ophiuroid* developing within it.

the genital clefts are enlarged to form distinct brood chambers. The openings of the clefts admit water, and thus aid in respiration. When the young are born viviparously they are more or less like the parent *Ophiuroid*, and have no free-swimming larval stage, but where the eggs develop freely in the water, the result is a strange swimming larval form utterly unlike a brittle-star. This so-called '*Pluteus*' is fancifully compared to a many-legged painter's easel, the legs being rods of lime which project from the body of the larva. Similar forms are characteristic of sea-urchins (*Echinoids*). As in other *Echinoderms*, the development is indirect. It is well known that in the panic of capture the brittle-stars justify their name by giving off their arms with singular facility. This pathological process is doubtless advantageous, for, like other *Echinoderms*, the brittle-stars have great powers of regeneration. They can grow new arms or new points, and thus recuperate their injuries; and in some species of *Linckia* and *Ophiaster* an isolated arm may produce other arms.

The brittle-stars are world-wide in their distribution, or occur at least in all seas yet dredged. The depth of their habitat varies greatly. 'More than two hundred species are restricted in their range to a zone of thirty fathoms,' but 'sixty-nine species descend below one thousand fathoms, and about eighteen below two thousand.' About fifty fossil species are known. Some are said to appear in the Silurian and Devonian, but about these very ancient forms not much is certainly known. In the higher Mesozoic strata, however, they become frequent, and are especially numerous in Jurassic beds.

The *Ophiuroids* form the most numerous class of *Echinodermata*, and may be divided into two distinct orders—(a) the *Ophiurida*, with unforked arms, which cannot be rolled up towards the mouth, and usually have distinct limy shields; (b) *Euryalida*, often with forked arms, which can be rolled up towards the mouth, and have not distinct limy shields.

Important Forms.—(1) *Ophiurida*.—Among the commonest British species are the Common Sand-star (*Ophiura texturata*), the Lesser Sand-star (*O. albida*), and the Common Brittle-star (*Ophiocoma rosula*). In North-European seas *Ophioglypha lacertosa* is very common. *Ophiopholis bellis* is viviparous. *Ophiactis oreus* divides spontaneously. The very widely distributed *Amphura squamata* is hermaphrodite, viviparous, and phosphorescent. *Ophiopsala aranea* is another luminous form. *Ophiotrix fragilis* is one of the most abundant species, and *Ophiotrix echinata* is common on Mediterranean shores. *Ophiomyxa* leads on to the *Euryalida*, which in its soft skin and general appearance it markedly resembles. (2) *Euryalida*.—The very curious (*Gorgonocephalus* or medusa-headed brittle-star is one of the best-known genera in this division. The arms are repeatedly forked, and as they curl in towards the mouth become intertwined in a living knot of the most fantastic appearance. *Euryale* is another important genus. One form has been occasionally caught on herring-nets off British coasts. They are sometimes called Basket-fish, Medusa-headed Starfish, or Argus Starfish.

See Forbes, *British Starfishes* (Lond. 1841); Hamann, *Beträge zur Histologie der Echinodermen* (Jena, 1885); Ludwig, in Bronn's *Thierreich*, and *Morphologische Studien* (1877-82); Lyman, *Challenger Report on Ophiuroidea* (1882); Romanes, *Jellyfish, Starfish, and Sea-urchins* (1885); Bell's *Catalogue of British Echinodermata* (1892); MacBride in the *Cambridge Natural History*, vol. 1. (1906); Bather in Lankester's *Treatise on Zoology* (1900).

Stargard, the chief town of Further Pomerania, Prussia, on the Hna, 22 miles by rail E. by S. of Stettin, has foundries, machinery and bridge-building works, and various mills and factories; pop. (1925) 32,575.

Starigrad (Ital. *Cittavecchia*), a small seaport of Yugoslavia, in the north-west of the Dalmatian island of Lesina or Hvar; pop. 4000.

Star Jelly. See *Nostoc*.

Starkenborg, a province of Hesse (q.v.), east of the Rhine.

Starling, a genus *Sturnus*, and family *Sturnidae* of Passerine birds. The family is a highly characteristic Old-World one, extending to every part of the Eastern continent and its islands, and even to Samon and New Zealand, but wholly absent from the Australian mainland. The Common Starling (*S. vulgaris*) is a beautiful bird, rather smaller than the song-thrush or mavis, brown, finely glossed with black, with rich metallic purple and green reflections, with a buff-coloured tip to each feather, giving the bird a fine speckled appearance, particularly on the breast and shoulders; in

advanced age it is more uniform in colour. The female is less brilliant than the male, and has the terminal spots larger. Both sexes are more speckled in winter than in summer. The starling is abundant in most parts of Britain, and nowhere more so than in the Hebrides and Orkneys. It is very abundant in nearly every district of England, but is less common in Cornwall and in Wales. It is found in all parts of Europe. It extends even to Iceland and Greenland. To the Mediterranean basin it is a cold weather visitor in enormous numbers; and it is also common in the north of Asia. Starlings make artless nests of slender twigs, roots, and dry grass (often in company with other birds), in hollow trees, in holes of cliffs, under eaves, in chimneys, or, readily, in boxes, which are often placed for them in trees or elsewhere near houses. Year after year they return and build in the same spot if the nest has been removed. They lay from four to seven pale-blue eggs, and breed twice, sometimes thrice, in a season. In autumn the young birds join to form flocks, which become augmented by the other birds, until there is a whole crowd of starlings executing aerial evolutions night after night before roosting time. In winter they disperse in search of food. Their food consists of worms, slugs, beetles, wireworms, and larvae, also berries; and since about 1896 they have greatly increased in numbers and become very destructive in cherry-gardens. Many ornithologists hold that three types of starling occur in Europe and north Asia, one with a green gloss, another (a Siberian) purple, and a third mixed; and that the influx of the stronger Siberian birds is driving the weaker green ones farther and farther west, even to Ireland, where starlings never nested till 1905. Introduced into Victoria and New Zealand as a farmer's friend, our starlings rapidly grew into a plague; the insect food supply ceased to suffice, and they took to grain and fruit. In Australia especially they became a serious economic problem; shooting and poisoning have failed to reduce their numbers. They breed not once or twice a season, but three and even five times, and are driving native

Starling (*Sturnus vulgaris*).

parrots, cockatoos, and laughing jackasses from their breeding-places. The starling becomes very pert and familiar in confinement, displays great imitative powers, and learns to whistle tunes, and even to articulate words with great distinctness. Its natural song is soft and sweet. In Spain, southern Italy, and Sicily the unspotted starling (*S. unicolor*) is found, and from Asia Minor to north-western India *S. purpurascens* and several other allied species. The Rose-coloured Starling (*Pastor roseus*), a crested bird with rose-pink back, shoulders, breast, and under parts, is an annual visitor to nearly every part of the British

Islands, and an irregular migrant over the greater part of Europe.

Star-nose. See MOLE.

Starodub, a town of Russia, 120 miles NE. of Tchernigov.

Star of Bethlehem (*Ornithogalum*), a genus of bulbous-rooted monocotyledons of the family Liliaceae, nearly allied to Squills and Hyacinths. The species are pretty numerous, natives almost exclusively of the eastern hemisphere, many of them of the Cape of Good Hope, and some of the south of Europe. The Common Star of Bethlehem (*O. umbellatum*), a native of France, Switzerland, Germany, the Levant, &c., is very common in flower-

Star of Bethlehem (*Ornithogalum umbellatum*).

gardens. Its flowers are large, six to nine, in a corymbose raceme, white and somewhat fragrant. This and other species of the genus have established themselves here and there in England. The name Star of Bethlehem is extended to other genera of Liliaceae (*Gagea*), Amaryllidaceae (*Hypoxis*), &c.—even to starwort and St John's wort. *Gagea lutea*, formerly called *O. luteum*, with yellow flowers, is found in some parts of Britain in woods and pastures.

Star of India. See INDIAN ORDERS.

Star of Night (*Clusia rosea*). See CLUSIA.

Stars are in general distinguished from other celestial bodies by their fixity of position in the celestial sphere, by the scintillation of their light, and by the fact that they show no appreciable size even under the highest telescopic power. The first quality renders them of great use in that department of astronomy which relates to accurate time-keeping and to measures of latitude and longitude. They form fixed points of reference whose place from their minuteness can be very accurately determined; and as they are far removed from terrestrial and even solar influence we can refer the motions of the earth and other members of the solar system to them as to unvarying landmarks. Themselves immovable, they determine for us our own movement. It is true that many possess minute motions of their own, but these, as we shall see, are so small as in most cases to affect but little in any moderate time the accuracy of such observations. This practical fixity of the stars enables us to determine two fixed points in the sky, called the north and south *poles* of the heavens. Our Pole-star (q.v.) is not far removed from the first of these. Stars near these points are but little affected by the diurnal motion of the heavens, moving with it in *small* circles, while

stars in the Equator (q.v.) move with great rapidity, requiring to complete the entire circuit of the heavens in the same time (twenty-four hours) as the others take to traverse their shorter paths. Thus the changing aspect of the heavens is confusing to an observer at first; but on attentive watching it is seen that all the various speeds and paths of the stars result from one simple motion, viz. the apparent revolution of the whole sky once in every twenty-four hours, as if it were a vast hollow ball hung on opposite points at the two poles. The observer looks as from the centre of this ball, and, were it not for the earth intercepting his view, would see stars on all sides, below as well as above him. At sea or in a sufficiently extensive plain he will see almost exactly one-half of this sphere, the earth hiding the other. A celestial globe represents this sphere, but is necessarily examined from *without*, while the sky is seen from *within*, which must be remembered in using such globes.

Owing to the sun's yearly motion the stars present different aspects at successive times. In June we see nearly one-half of the sky at midnight. By December the sun, pursuing his annual track, has gained a position among the stars we saw at June midnight. They are above the horizon when the sun is in the meridian at noon. At midnight in December we therefore see the stars in the other half of the heavens. At intermediate seasons the condition of things is of course intermediate also. Speaking generally, the starry sky at midnight on the first of any month is the same as that visible at ten o'clock in the evening of the first of the following month, while the ten o'clock aspect in the first case has of course moved to eight o'clock, and so on.

On the inner surface of the sky sphere the stars are irregularly scattered in groups called Constellations (q.v.). From these groups the stars are named by adding a letter or number to the name of the group. The Greek alphabet is used for the brighter stars— α denoting the brightest, β the next brightest, and so on. Roman letters are used when the Greek ones are exhausted, and afterwards numerals. Sometimes, however, the stars are named by their number from some catalogue in which their positions are given. Thus B. 750 means No. 750 in the catalogue of stars made from Bradley's observations about 1755. In recent years a very extensive catalogue of stars has been determined photographically by co-operation of a large number of observatories. This has been completed for a large part of the sky.

The Scintillation (q.v.) or twinkling of the stars, by which they are easily distinguished from the planets, is due to disturbances in our atmosphere, combined with the fact that the stars are to us mere luminous points. It is magnified by the telescope, and becomes often then sufficient to transform the star into something like a tangled mass of worsted. The various points on the surface of a planet, the sun, or the moon are similarly affected, causing an indistinctness of telescopic vision, which when the air is much disturbed renders accurate observation impossible. But the star, being one point of light, twinkles as a whole, while the planet, sun, or moon, being even in the smallest case many points, does not twinkle as a whole, and the *average* of its rays gives a steady impression to the eye. Scintillation is most observable on nights when the atmosphere is disturbed, and always greatest at the horizon, being least at the zenith and on quiet nights.

Movements of Stars.—The fixity of the stars relatively to one another is found to be only approximately true when sufficiently refined observations are made, or when they are compared after

a sufficient interval of time. Halley, by comparing the positions of Sirius and some other bright stars given in Ptolemy's catalogue with his own observations, found that they had moved through angles of about one-third the diameter of the moon. All the stars are, in fact, in motion. The largest 'proper motion' known, that of a very faint but near star, is $10''$ a year, so that the star will move a distance equal to the diameter of the moon in 180 years. About two hundred stars are known to have proper motions of more than $1''$ annually, but many thousands are known which have proper motions of a few seconds a century. These are at first sight very irregular. Herschel detected a general tendency to move directly away from a point in the neighbourhood of the bright star Vega. This he interpreted as due to a movement of the sun, carrying the whole solar system with it, in an opposite direction. Herschel's discovery has been confirmed many times, and, since the velocity of the sun has been determined by spectroscopic observations of the stars, has served as a most valuable method of determining the mean distances of stars of different magnitudes or of different colours.

A further systematic character in the proper motions of the stars was discovered by Kapteyn in 1905, who found that they were divided into two great streams moving in opposite directions along a line parallel to the plane of the Milky Way. It is not to be understood that the stars are moving in exactly parallel directions, but there is a general drift in these directions superposed on peculiar movements of their own. There are, however, several groups of stars, such as several of the stars in the Great Bear, and particularly a group in the constellation Taurus, discovered by Lewis Boss, to which the names of 'Moving Clusters' are given, and which consist of assemblies of stars having parallel and equal movements in space.

The application of spectroscopy to the stars enabled the velocities towards or from the earth to be determined in a large number of cases. If a star is approaching us, then the positions of the lines in its spectrum will be shifted to the violet side of their normal positions, and if receding from us, towards the red. This is known as Doppler's principle, and the amount of shift enables the velocity of approach or regression to be determined in kilometres per second. The first attempts by Huggins to put this into practice met only with partial success. The application of photography by Vogel, and still more the careful design of the large spectroscope mounted on the 36-inch refractor of the Lick Observatory, enabled results of high precision to be attained. For fainter stars the large reflecting telescopes of Mount Wilson and British Columbia have been very successful. It is found that the linear velocities of stars, after the effect of the earth's movement round the sun and the motion of the solar system in space have been eliminated, have average velocities to or from the earth of from 10 to 20 kilometres a second, and in individual cases are much larger. Discussion of the velocities found spectroscopically confirms the direction of the solar motion found from 'proper motions,' and also furnishes a value of the amount, viz. 19 kilometres a second. It has also confirmed the two-stream movement discovered by Kapteyn. The discussion of 'proper motions' and 'radial velocities' has led to a number of conclusions as to the difference in the movements of different kinds of stars. One of the most interesting of these, though it still needs more confirmation, is that massive stars move more slowly than those of smaller mass, presenting analogy to the equipartition of energy in a mixture of gases.

Stars are classed in *magnitude* according to their brilliance. The brightest stars, some 20 in number, were called by Hipparchus 1st magnitude; the next brightest, 2d magnitude; down to those just visible to the naked eye, which he called 6th magnitude. Later a decimal notation was introduced so that a star of 1^m.2 is one-fifth of the way between stars of magnitude 1^m.0 and 2^m.0. The accurate determination of magnitudes led to the necessity for a definite scale. A star is one magnitude fainter than another when we receive from it $(2.512 \dots)^{-1}$ as much light, two magnitudes fainter when we receive $(2.512 \dots)^{-2}$ as much light, and so on, so that for five magnitudes difference the ratio is $(2.512 \dots)^{-5}$, or $\frac{1}{100}$. The faintest stars which have been photographed with large reflecting telescopes are beyond the 21st magnitude, and thus give less than one hundred millionth of the light of a star of magnitude 1^m.0. This scale is carried backwards, so that Arcturus is of magnitude 0^m.3, Sirius of magnitude -1^m.4. The full moon gives as much light as a star of magnitude -11^m.2, and the sun as much as a star of magnitude -26^m.7. This scale of magnitudes has the advantage of agreeing fairly well with magnitudes assigned before its adoption, and is now universally employed.

The number of stars increases with the magnitude. To the naked eye from 6000 to 10,000 are visible when both hemispheres are included. With a small telescope of two inches aperture the number is increased to more than half a million. With exposures of one hour with a 12-inch telescope of short focus, Franklin Adams photographed nearly 70 million stars in the whole sky. From the rate at which the number of stars increases and the diminution of this rate with fainter magnitudes, it is inferred that the number of stars in the sky, though very great and of the order of five thousand millions, is finite. The following table gives the numbers brighter than 2^m.0, 3^m.0, &c. obtained from the photometric researches of the Harvard College Observatory:

Magnitude	Stars.
2 ^m .0	41
4 ^m .0	454
6 ^m .0	4,750
8 ^m .0	
10 ^m .0	373,000

As higher magnitudes are reached, the number of stars from one magnitude to the next being less than 2.512, the total amount of light from stars of one magnitude is less than that from the preceding magnitude. The total amount of light from all the stars together is a little less than would be given by 1000 stars of the 1st magnitude, and is about one-hundredth part of the light of the full moon.

Distances.—The great variety in the brilliance of the stars arises from two causes: (1) difference in distance; (2) difference in absolute luminosity. There is a great range in the absolute luminosity of the stars, so that were they at the same distance from us they would still differ from one another by more than 10 magnitudes. As regards *distance*, if a star were moved ten times as far away, we should receive one-hundredth as much light from it, and it would appear exactly 5 magnitudes fainter. The determination of the distances of the stars has been one of the great historic problems of astronomy. When the Copernican system was introduced, and the earth was shown to describe a vast orbit round the sun, the difference in its position at opposite times of the year furnished a base-line from which to measure stellar distances. These are so great in proportion to the distance of the earth from the sun that astronomers sought for centuries before they obtained a measure of the distance of a single star. In the

course of this search Bradley discovered 'Aberation of Light' (q.v.) and Herschel the existence of systems of double stars circulating around one another. Success came almost simultaneously to three astronomers about the year 1838. Henderson at the Cape Observatory found for a Centauri a Parallax (q.v.) of 1^m.0, corresponding to a distance 200,000 times that of the sun from the earth. Struve at Dorpat found a distance of 800,000 times that of the sun for the bright star Vega. Bessel at Königsberg found a distance of 600,000 times that of the sun for the fainter but quick moving star 61 Cygni. These values are fairly correct, but have been altered somewhat by modern observations. Bessel used an instrument called a *heliometer*, made by the great optician Fraunhofer, and specially designed for the accurate measurement of a star from neighbouring stars. The same kind of instrument was used throughout the 19th century, and in the hands of Auwers, Brunnov, Peters, Gill, Elkin, and others led to a good determination of the distances of some 50 to 100 stars, Gill's measures at the Cape Observatory being particularly accurate. In the present century large photographic telescopes have been employed with conspicuous success. Pioneer work was done by Hinks and Russell at Cambridge and by Schlesinger at the Yerkes Observatory. Working in concert through a committee, of which Schlesinger is chairman, a number of observatories in the United States with Greenwich in England have determined the parallaxes of some three thousand stars. If the radius of the earth's orbit round the sun (92 million miles) be called *a*, the distance at which it will subtend an angle of 1" is 206,265*a*. This distance is called one *parsec*, and light will take three years to transverse it. There are known to be 26 stars nearer than 5 parsecs, 104 nearer than 10 parsecs, and 700 nearer than 35 parsecs. In these counts double stars are counted once only. Probably the number found nearer than 5 parsecs is about two-thirds of the actual number within this distance, but for the larger distances becomes more and more incomplete. These figures serve to show how widely apart stars are scattered in comparison with their sizes. A model would be supplied by 40 or 50 tennis-balls inside a globe the size of the earth.

When the distances have been determined it is easy to find the actual *luminosities* of the stars in comparison with the sun. Luminosities are usually expressed by means of *absolute magnitudes*, i.e. the magnitude a star would have if brought to a distance of 10 parsecs, at which its parallax is 0^m.1. The following table shows how widely these differ:

Sun	1	
Sirius	30

Angular Diameters.—In a few instances the actual diameters of stars have been measured. A star seen in a telescope when the air is very steady is a small bright disk surrounded by a dark ring, then a bright ring, and so on. This appearance is an optical phenomenon, and the larger the object-glass, the smaller is the central disc. With the large 40-inch glass of the Yerkes Observatory the angular diameter of the central disc is 0^m.10, while with a 4-inch glass it is 1^m.0. Thus, however small the actual angular diameter of a star may be, the star cannot be seen as a smaller disk than 0^m.10 with a 40-inch glass. By means of an interferometer applied to the 100-inch reflector of

the Mount Wilson Observatory by Michelson, the angular diameter of Betelgeuse was measured as $0''.041$. As the parallax of Betelgeuse has been measured, the actual size of this star has been found. If its centre were at the centre of the sun, the star would extend beyond the earth. This enormous size was in agreement with a prediction by Eddington and others from consideration of the amount of the magnitude and colour of the star.

The difference between the *colours* of different stars is apparent to the naked eye. Aldebaran and Betelgeuse are red, while Sirius is a bluish white, and Arcturus and Capella are yellow like the sun. Colours of stars indicate differences of temperature: the blue stars being hottest, and the red coolest. On this account they have been studied with some care. The eye-estimation does not admit of great accuracy. Two other methods are employed. The difference of the photographic magnitude (which differs from the visual magnitude since photographic plates are more sensitive to blue light than the eye) from the visual magnitude gives the *colour index*. If the visual and photographic magnitudes are taken as the same for blue stars there is a progressive difference as redder stars are taken, which in extreme cases may amount to two magnitudes. Another method is by determination of the *effective wave-length*, or the position in a very short spectrum of the wave-length where the intensity on an ordinary photographic plate is greatest.

These methods of determining colour, though useful when it is desired to examine large numbers of faint stars, are subsidiary to the investigations by means of the *spectroscope* (see SPECTRUM). This was first applied to the stars about 1860 by Huggins in England, Secchi in Italy, and Rutherford in America. It has been developed to a great extent with the introduction of large telescopes and photographic methods. The original classification of Secchi has been developed and extended; but putting the matter broadly, it may be said that the great majority of stars fall into three classes:

- I. BLUE STARS.—Those having a continuous spectrum crossed by broad hydrogen lines.
- II. YELLOW STARS.—Those having a continuous spectrum crossed by sharp metallic lines like the sun.
- III. RED STARS.—Those having a continuous spectrum crossed by bands.

In the blue stars the spectrum extends far into the ultra-violet, but less so in the yellow stars, and still less again in the red stars.

The essential point in the spectroscopic classification of the stars is that it is *linear*. Stars can be arranged by their spectra in one continuous order, differing from one another by insensible gradations. The differences in spectra cannot then arise from differences of chemical composition, which would give rise to many different varieties. The spectroscopic classification is mainly one of *temperature*. The hottest stars (known in the Harvard classification as B stars, and showing certain lines of helium, as well as the broad lines of hydrogen) send light to us from a source near their surfaces which indicates a temperature of $20,000^{\circ}\text{C}$. The stars like Sirius, with broad hydrogen lines, have an effective temperature of about $10,000^{\circ}\text{C}$. When we reach the yellow stars like the sun the temperature is about 6000°C , while the red stars like Betelgeuse and 61 Cygni are the coolest, with temperatures of about 3000°C .

The *effective temperatures* of stars are determined from the distribution of light in the continuous spectrum. In a perfect radiator, if the intensity of the light be plotted against the wave-length, the

curve rises to a single maximum, and the temperature is given by the formula $\lambda(\text{max.}) \times \text{Temp.} = \text{Const.}$ There are difficulties in the application of the formula, as the stars are not perfect radiators, but are surrounded by absorbing atmospheres. Nevertheless the results obtained from its use probably give fairly correct values of the temperatures of the stars near their surfaces.

In the comparison of the spectra of stars and other celestial bodies, Lockyer drew attention to the important role of lines which he called 'enhanced,' from the fact that their intensity in a spectrum obtained from an electric arc was strengthened as compared with that of the arc. The researches of A. Fowler have thrown much light on these lines which occur when outer electrons of an atom are torn off or the element is 'ionised.' The temperatures and pressures at which different elements are ionised may be calculated. By examination of the lines belonging to different elements in the stars the extent of the ionisation of their atmospheres was determined by Saha in 1921, and their surface temperatures inferred. The method was subsequently developed by R. H. Fowler and E. A. Milne. The results are in reasonable accord with those obtained from the intensity curves of the continuous spectra giving the results of a previous paragraph, except for the hottest stars.

Although the spectra of stars naturally arrange themselves in an order which is essentially one of temperature, differences in the intensities of some of the enhanced lines have been found by Adams and Kohlschutter, which enable a discrimination to be made between stars of great and small luminosity. By comparison of the intensities of neighbouring lines, one of which comes from an ionised element and the other un-ionised, a measure of the luminosity is obtained. The necessary constants for stars of different temperatures are found from stars whose luminosities are already known. This method, though of an empirical character, is of great importance, as it gives a means of determining the luminosities and thence the distances of stars which are beyond the range of trigonometrical determination, and is still in course of development.

Double Stars.—Herschel, in searching for stars which are near one another as seen by us, and (supposing one to be distant and the other comparatively near) could thus be employed in the determination of parallax, discovered pairs of stars which are physically connected, or *double stars*. The observation of these bodies has been continued by many astronomers to the present time, among whom W. Struve, O. Struve, Dembowski, Burnham, Hussey, and Aitken are the most prominent. Large telescopes are generally required for these observations, as the stars are frequently so near that they are only seen as single stars in small telescopes. These stars are found to circulate round one another in elliptic orbits, and their movement is in accordance with the description of an ellipse according to Kepler's laws, but seen projected on a plane perpendicular to the line of sight.

The periods of making a complete circulation round one another for some stars are only a few years, and for others many thousands. Again, the component stars are sometimes of nearly equal brightness, and in others, e.g. Sirius, the difference amounts to as much as 10 magnitudes. Double stars have played an important part in stellar astronomy, as they have enabled astronomers to determine the *masses* of stars. When the distance of a star is known, then, from the angular distance apart of the two components measured in the telescope, their linear distance is derived. Calling a the semi-major axis of the orbit measured in units of the earth's distance from the sun, P the period of revolution

in years, M and m the masses of the two components, then Kepler's third law gives $M + m = \mu a^3$

This formula gives the sum of the masses in units of the sun's mass. It is found in this way that the masses of stars do not show a great range like the luminosities, but generally lie between one-fifth and twenty times the mass of the sun.

Many stars which are too near to be resolved into their components at the telescope have been proved to be double by spectroscopic observations. In the course of its orbital motion round its companion a star is sometimes approaching and sometimes receding from us. The variation in velocity is indicated by a small shift in the lines of the star's spectrum from their normal positions. If the components are of nearly equal brightness, lines belonging to each of them are shown. But if one is much brighter than the other the spectrum of the brighter component alone is impressed on the photographic plate. From a sufficient number of observations of velocity the periods and other elements of the orbits may be obtained, as in the case of visual double stars. It is not, however, possible to find a , but only $a \sin i$, where i is the angle between the plane of the orbit and the plane perpendicular to the line of sight. The quantity $a \sin i$ is found in linear measure independently of the star's distance. The number of these close binary stars is very considerable, amounting to no less than one star in five. The components are closer together, and have shorter periods than visual binaries. Although the masses of individual stars cannot be found, in consequence of the indeterminateness of $\sin i$, statistical treatment of numbers of stars confirms the conclusion that the masses of stars do not show any great range.

There are many stars whose light is *variable*. Some of these go through their changes in a few days, and others have long periods exceeding 150 days. The causes of variation in the two cases are entirely different. *Short-period variables* are divided into *eclipsing variables* and *Cepheids*. The variation in the former class is caused by the revolution of the two bodies round one another, so that partial eclipses occur periodically as seen from the earth. Algol is a star of this kind. It goes through its changes in approximately 70 hours. For the greater part of this time it remains nearly at magnitude $2^m.3$. In five hours it drops to $3^m.5$ (i.e. to one-third of its former brilliancy), and in five hours more has risen again to $2^m.3$, near which it stays for another sixty hours. It is clear that in these cases the bodies must generally be large in comparison with their distance apart. In the case of Algol, the diameters of each of the bodies are about $\frac{1}{4}$ times the distance between their centres, but one star is much more luminous than the other. Spectroscopic observations confirm the conclusions arrived at from the study of the way in which the light regularly increases and decreases.

The study of eclipsing variables gives us a direct knowledge of the *mean densities* of stars. If a_1 and a_2 be taken as the radii, ρ_1 and ρ_2 the densities, b the distance apart of the centres, and P the period of the light changes, then by Kepler's third law

the combined mass $\frac{4}{3}\pi\rho_1a_1^3 + \frac{4}{3}\pi\rho_2a_2^3$ is proportional to $\frac{b^3}{P^2}$. Now the ratios $a_1 : a_2 : b$ are determinable

from the way in which the light varies, and the period P is also known. It was thus found that there is a great diversity in stellar densities. While the mean density of the sun is 1.2 that of water, Algol has a density of 0.07, and many stars have been found to have very small densities, some even much less than that of atmospheric air.

These results are confirmed and extended from those stars whose masses, distances, and luminosities are all three known or can be reasonably assumed. From the distance and luminosity (making due allowance for colour) the radius of the star can be determined, and then from the mass the density is deducible. Some stars are clearly huge globes of gas, others from their density might be inferred to be partly liquid or solid, though Eddington has given reasons (see SIRIUS) for believing all to be of gaseous constitution.

Cepheids.—Another class of short-period variables are called Cepheids after δ Cephei, which is a typical example. In $5\frac{1}{2}$ days this star regularly changes its magnitude from $4^m.3$ to $3^m.6$, taking $1\frac{1}{2}$ days to go from faint to bright, and 4 days from bright to faint. These changes are accompanied by changes in the radial velocity, the star apparently approaching us when it is brightest, and receding when it is faintest. These phenomena cannot be explained by the rotation of a bright star around a darker companion, but are attributed to a pulsation in size, an explanation which is not, however, free from difficulties. Generally, the extent of variation of Cepheids is not greater than 1 magnitude, and the period may be anything from 1 to 60 days. These stars are all of great luminosity.

Hertzsprung showed how these stars may be used to gauge very great distances. Miss Leavitt, from the mode of variation of light, had detected a number of Cepheids in the lesser Magellanic Cloud—a feature in the southern sky like a bit torn off the Milky Way—and noticed that the period of variation was related to the *apparent* magnitude of the star. Hertzsprung observed that these stars, being in the Magellanic Cloud, were all at the same distance from us, and that the period of variation was thus dependent on the *actual* luminosity of the star. This is a universal property of Cepheid stars. From a study of the near Cepheids, whose distance can be determined, it has been shown by Hertzsprung and by Shapley that Cepheids of period $1\frac{1}{2}$ days have absolute magnitude $-1^m.0$, those of period 4 days $-2^m.0$, those of period 8 days $-3^m.0$, and so on. These are the magnitudes Cepheid variables would have if their parallax were $0^{\circ}.1$, or their distance 10 parsecs, i.e. two million times the distance of the sun. If then, e.g., a Cepheid variable of period 8 days has an apparent magnitude $12^m.0$, the difference from its absolute magnitude is $15^m.0$. A diminution of $5^m.0$ magnitudes implies a ten-fold distance. Thus the distance of this star would be inferred as 10,000 parsecs. By reasoning of this kind, the distance of the Magellanic Clouds has been inferred to be 30,000 parsecs. Quite recently Hubble has found very faint Cepheids in the *Andromeda Nebula*, and has inferred a distance of 300,000 parsecs, a distance travelled by light in a little less than a million years.

The *long-period variables* are usually irregular both in the length of their period and the extent of their range. They are always red stars. Mira or α Ceti is the best-known example. It has a mean period of 33 days. At its brightest it may be anything from $2^m.5$ to $5^m.0$, and at its faintest from $8^m.5$ to $9^m.5$. No variation of its radial velocity is indicated by spectroscopic observations.

Besides the stars which repeat more or less regularly their variations of light, a number of *Nova*, or new stars, have appeared in the heavens at different times. The appearance of one of these stars is said to have caused Hipparchus to make his catalogue of stars. In 1572 one appeared in Cassiopeia, and was discovered by Tycho Brahe. This was so bright that it was visible in the daylight. Within the present century *Nova Persei*,

discovered by Anderson in 1901, reached the magnitude $0^m.0$, and *Nova Aquile*, discovered in 1918, the still brighter magnitude $-0^m.5$. The history of these stars is very similar. A faint star, afterwards identified on photographs taken before the outburst, in a few days increases in luminosity ten thousandfold, and in the course of months falls gradually, with some oscillations in magnitude, to its previous brightness. Spectroscopic observations show very great displacements of lines due to hydrogen and calcium, as though gases were approaching us from the star with velocities of thousands of kilometres per second. The character of the spectrum also goes through a series of very remarkable changes. The genesis of these stars is not understood, and whether the outbursts are due to collision or explosion is unknown.

Following previous researches of Lane, Ritter, Sampson, Schwarzschild, Eddington, and others, Eddington has investigated mathematically the *internal constitution* of stars. The stars of low density and great volume (and other stars have later been brought into the same category) are gaseous throughout, and obey the gas law connecting pressure, density, and temperature. In a steady state the attraction of gravitation is balanced at all distances from the centre partly by the elastic force of the gas and partly by the pressure of the radiation striving to escape outwards. The temperature increases from the circumference to the centre, and the outflow of radiation is constantly obstructed by the matter which it has to traverse. For the bright component of the double star Capella the *data* from observation are as follows: The mass is 4.18 times that of the sun, and the radius 13.74 times, while it radiates 127 times as much energy, its 'effective' temperature being 5200°C ., or somewhat less than that of the sun. Eddington concludes that at the centre the temperature is 7 million degrees, the density 40 times that of atmospheric air at the earth's surface, and the pressure 22 million atmospheres. About 0.7 of this pressure is gas pressure, and 0.3 the pressure of radiation. At the enormous temperature and pressure inside the star the atoms are largely stripped of their electrons, and the radiation is mainly of the short wavelength of the X-rays produced in the laboratory. For the sun the temperature at the centre is calculated to be 40 million degrees.

While gravity tends to condense a star, pressure of radiation tends to expand it. Eddington compares the pressure of radiation with gas pressure in globes of various sizes. For globes of much smaller mass than the sun it is quite trivial, for a globe half of the mass of the sun it is 10 per cent. of the whole pressure, while for a globe of mass 50 times that of the sun it is 85 per cent. This pressure, according to Eddington, is the main disruptive force which prevents the masses of stars increasing beyond a certain limit. On the other hand, a minimum mass is required for a globe of gas to acquire sufficient temperature to shine as a star. An explanation is thus suggested, though not a definite proof, of the cause why the masses of stars lie within comparatively narrow limits.

Evolution.—Astronomers are in the position of a person who has a momentary view of a crowd of people of all ages, and then tries to infer the life-history of a human being. Huggins took the view that the order of development was the order of the spectroscopic classification from the hot blue stars down to the red stars. Lockyer maintained that red stars, like Betelgeuse, intrinsically many times more brilliant than the sun, were in a wholly different stage from faint red stars a hundred times less brilliant than the sun. He therefore formulated a scheme of development beginning with

extremely diffuse red stars, which gradually condensed and grew hotter till their temperature reached a maximum in the stage of blue stars, when they grew colder, and went through the yellow stage again back to the red, contracting in bulk all the time. His method of discrimination of stars in which the temperature was increasing from those in which it was decreasing was not satisfactory, and his views were not generally accepted. In 1905 Hertzsprung gave cogent arguments in support of the existence of 'giant' and 'dwarf' stars; and in 1912 Russell marshalled together with great skill the numerous facts which had been elicited from recent observations in support of a similar theory. Red stars were, he found, of two groups—'giants,' roughly of absolute magnitude $0^m.0$ (100 times as luminous as the sun), and 'dwarfs,' of magnitude $9^m.0$ (40 times as faint as the sun)—and there were no stars of intermediate brightness. Passing towards the yellow stars he found 'giants' still of magnitude $0^m.0$, and 'dwarfs' of magnitude $5^m.0$ (as bright as the sun). Passing still further towards the blue stars, the 'dwarfs' approached more nearly to the 'giants.' Again, stars show little difference in mass, but very great differences in density. He therefore formulated an evolutionary scheme beginning with red stars of great volume and small density. As they contract under the influence of gravitation their volume diminishes, but their temperature rises. The increase of brightness compensates for the diminution of surface, and they still remain 'giants.' This process continues till the stars reach their maximum brightness at the blue stage, when their mean density is approximately one-tenth of that of the sun (and of water). They then cease to obey the gaseous laws, and with further contraction become cooler. Conditions are now reversed, and a diminution of surface takes place with a diminution of surface brightness, and the stars fall into the 'dwarf' yellow and red stages.

The following table (derived from *General Astronomy*, by H. Spencer Jones) gives a number of stars in these successive stages:

'GIANTS.'			
	Absolute Magnitude.	Diameter (Sun=1)	
μ Gemmorum	+0.3	65	Red.
Aldebaran	-0.2	48	
Arcturus	+0.1	24	
η Draconis	-0.7	21	Yellow.
α Leporis	-1.0	9	
Regulus	-1.1	5	
β Centauri	-1.3	4	Blue.
'DWARFS.'			
	Absolute Magnitude.	Diameter (Sun=1)	
Sirius	+1.3	2.0	Blue.
Procyon	+2.0	2.0	
λ Serpentis	+4.1	1.5	
11 Leo Minoris	+6.2	1.5	Yellow.
61 Cygni	+8.0	1.1	
Lacaille 9352	+9.7	0.9	Red.
Lalande 21185	+10.7	0.6	

The division of stars into 'giants' and 'dwarfs' is an observational fact, and the order of evolution is still thought to be that indicated above. But the dynamical basis of the theory cannot be maintained, for it implies that the only source of the energy dissipated as radiation is acquired by contraction of the mass under gravitation. As shown by Helmholtz and Kelvin fifty years ago, this process furnishes sufficient energy to last only 30 million years. But there is conclusive evidence from the consideration of radio-active minerals in rocks and from other sources, that the age of the earth's crust is 1000 millions, and the age of the sun must be considerably greater.

In the last few years the question has been reconsidered in the light of the large store of

energy which physicists have discovered to be contained in the atom. There can be little doubt that the immense stores of energy radiated from the stars are in some way derived from sub-atomic sources in the interior of the stars themselves. The transmutation of elements would produce a supply of energy many times larger than that obtainable by contraction under gravitation. A supply much greater still will be given by the annihilation of matter. In the violet commotion in the interior of a star an electron and proton may collide, mutually destroying one another as matter and converting themselves into radiation. (See Jeans in *Nature*, 4th December 1926; and Eddington, *Internal Constitution of Stars*, chap. xi.)

By radiation stars are constantly losing mass which, on the theory of relativity, is another mode of expressing energy. The sun is losing 5 million tons per second, and Capella 500 million tons per second. Although these seem large amounts, the time taken for an appreciable diminution in their masses is many millions of years. This implies a slow development from heavy to less massive stars. Eddington has found a remarkable relationship between the masses and luminosities, which, with few exceptions, appears to hold for 'dwarfs' as well as 'giants.' According to a theoretical investigation which is confirmed by observation, masses and luminosities are connected as follows:

	Luminosity (Sun=1)
-4.3	3200
-2.7	1300
-0.3	130
+5.0	1
+0.40	+8.8
+0.25	+10.8

Thus the most luminous stars are the most massive, and the history of a star is a continuous loss by radiation of luminosity and mass with a shrinkage of volume and increase of density. The star gradually burns itself out. Apparently the gas laws apply to nearly all stars, even where the density is greater than that of water. (See *SIRIUS*.)

The large diffuse stars, though at a lower internal temperature than stars like the sun, are radiating energy at a much greater rate. It appears from this that the new stars have some source of energy which has been used up in the older ones. Jeans concludes that these stars contain atoms of greater atomic weight than uranium, having greater capacity for the generation of radiation. For all these new and somewhat speculative researches which are not free from difficulties, reference should be made to the writings of Eddington and Jeans.

Stellar Universe.—The number of stars may be tentatively estimated at 5 to 10 thousand millions. They are arranged, as was pointed out by Herschel, in a form somewhat like a watch or a penny, with the Milky Way as fundamental plane. In the plane of the Milky Way the clustering of the stars is irregular in great star clouds, of which the densest is in Sagittarius. In the direction perpendicular to the Milky Way the stars have thinned out to a very great extent at a distance of 1000 parsecs. In the plane of the Milky Way the stars extend to a hundred times this distance. The solar system is a little out of the plane of symmetry; but it is hardly possible as yet to estimate its distance from the centre of the Galactic system. There are, in addition, groups of stars, so-called 'island universes,' which appear to us as spiral nebulae—that in Andromeda being the nearest—and about ten times as far away as the boundary of the Milky Way.

See Newcomb, *The Stars* (1902); Eddington, *The Stellar Universe* (1912); Jeans, *Cosmogony and Stellar*

Dynamics (1919); H. S. Jones, *General Astronomy* (1922); Stratton, *Astronomical Physics* (1925); Eddington, *The Internal Constitution of Stars* (1926); Jeans, 'Recent Developments of Cosmical Physics,' in *Nature*, 4th December 1926.

Stars and Stripes. See FLAG.

Star-stone, a kind of Supplie (q.v.).

Star-thistle. See CENTAUREA.

Start Point, a projection of the coast of Devon, 8 miles S. of Dartmouth, forming the south eastern extremity of the county. It is crowned by a lighthouse (92 feet), whose light, 204 feet above high-water, is visible for 20 miles.

Starvation. See FAST.

Starwort, or STITCHWORT, a genus (*Stellaria*) of Caryophyllaceae. See CHICKWEED. The name Starwort is also applied to the genus *Aster* (q.v.).

Starwort, WATER, is a name given to the genus *Callitriche*, which by itself forms the family Callitricaceae, whose affinities are very obscure. Engler and others place it near Euphorbiaceae. The genus is almost world-wide in distribution. Several species are common in ditches and ponds in Britain. Land forms are found, but normally the water-starworts are water plants. The stem is thin and frail. The leaves are opposite, the lower submerged leaves somewhat lengthened and narrow, the uppermost crowded in a floating rosette. The flowers are very small, with no sepals or petals. The male flower consists of a single stamen; the female of two united carpels, with a 'false septum' (forming four locules, each with one ovule), and two styles. The fruit is a schizocarp.

Stassfurt, in the Prussian province of Saxony, on the Bode, 20 miles S. of Magdeburg, has no-mills and chemical-works, but is notable chiefly for its ancient salt-works, which mine potash and rock salts; pop. 20,000.

Staten Island, (1) a beautiful island, forming (since 1898) part of New York city. It is separated from Long Island by the Narrows, and from New Jersey by the Kill van Kull and Staten Island Sound. Area, 57 sq. m. Its shores are dotted with villages, and its heights crowned with villas. Forts guard the entrance to the Narrows. The island constitutes the southernmost borough (Richmond; pop. 116,531) of New York. (2) An Argentine island separated from the south-east point of Tierra del Fuego by Le Maire Strait (16 miles). It is long (45 miles) and narrow in shape, with steep coasts penetrated by deep fiords, and rises to nearly 3000 feet. Snow covers it almost all the year.

State Papers. See RECORDS.

State Religion. A state religion and a national religion are two different things. A nation may, with more or less of universal concurrence, accept a certain type of religion—as the people of the United States for the most part accept Christianity—yet they may not commit to their government the task either of representing officially or of maintaining financially their religion. In that case it is a national but not a state religion. Wherever, on the other hand, we witness either establishment or endowment committed to the government—even if, as in Ireland till 1869, the religion thus favoured is very far from being national—there we have the spectacle of a state religion. Now such a spectacle almost invariably presents itself to our view on the first emergence of any people from tribal confusion into national order. The previous multiplicity of local gods and diversity of religious ideas became fused together into a conglomerate state religion, and then were compacted by time and by priestly labour into a sort of incoherent unity. As to any rights of the individual conscience to worship according to its

own private judgment, such a notion had not so much as dawned upon men's imagination. In ancient China, for instance, public worship was regulated down to its minutest details by six ministers of state, who were responsible even for the sacred music and religious dancing. The emperor alone might offer sacrifice to the supreme spirit; the nobility might do homage to the various subordinate spirits of the earth; the high officials to the spirits of house and home, and so on, in ever-descending order. Even the soothsayers, magicians, and spirit-charmers were reckoned among public functionaries of the state. Nor did the reforms of Confucius (500 B.C.), nor yet the uprise of the Taoists and the Buddhists, alter this Erastian character of the Chinese system.

In ancient Mesopotamia, too, the supreme head of the state religion was the king; he alone could penetrate into the innermost sanctuary, he alone could offer sacrifice for the whole people; and from the ruins of the palaces at Nineveh and Babylon come the records that unfold to us the sacred history of this remarkable form of state religion; displaying to us the gradual amalgamation of a hundred tribal beliefs, the ultimate emergence of a Sennacherib or a Nebuchadnezzar to rule, like some incarnation of divine despotism, over all the prostrate nations, and the absolute predominance of the civil over the ecclesiastical power.

In India, on the other hand, a religion which began with the lay poets who composed the Vedas emerged at last completely organised on a caste system; and this system assigned irrevocably the first place to the priesthood and the second place to the secular authorities. In ancient Egypt something analogous may be observed. Here, indeed, as in ancient Mesopotamia, the local gods long held sway, and suffered at last agglomeration into the state religion. But the greater state deities were immensely more powerful. They were endowed with vast estates; they employed thousands of labourers, agents, scribes, overseers. The Egyptian state religion dominated the entire life of the people, and for long centuries reigned in uncontested supremacy.

When we cross the sea, however, and disembark in imagination among the bright and mobile populations of southern Europe, we soon find that these vast state religions of the eastern river-valleys have been left behind. The gods of ancient Greece were as Bohemian and passionate as their worshippers, and no crushing priestly tyranny could find a footing among its small and quarrelsome communities. Yet even there, as childish fancies about Olympus and its happy denizens hardened into dogma, and nursery legends became endeared to the people and fixed in beautiful forms of epic, dramatic, and statuary art, then here, too, a state religion came into being. To ridicule the gods became perfidious, even to an Aristophanes; to mutilate their images became an unpardonable crime; and to replace them by other and worthier conceptions of divine things was a treason which even a Socrates must expiate by his death. In more grim and serious Italy the mingled native and Greek theology became characteristically transmuted into downright law. Offences against the state religion were supposed to bring down on army and navy, on agriculture and commerce, the anger of a justly indignant heaven. And as for any such unheard-of novelty as a catholic or world-wide religion, unacknowledged as its own even by any subject state—still more, for any preposterous claim to worship according to each man's private conscience—away with people possessed of such ideas 'to the lions!' For Christians, therefore, and all state heretics of that sort there was but one answer to be made, *non licet esse vos*, you have no right to exist, you have placed

yourselves outside the protection of the Roman empire.

With the conversion of Constantine (313 A.D.), of course, all this was entirely changed; but it was only changed by the parts being reversed. The state religion had now become Christian; and paganism was ere long held to have no right to exist. It is true that with Christianity a new and gentler spirit had found entrance, and that a day might certainly be foreseen when men would cease to persecute and to be persecuted for religion; but that day did not, in fact, come for more than a thousand years. Under the imperial legislation of Justinian the orthodox alone possessed the full privileges of citizenship. And even when the Roman empire was broken up at all points by the irruption of the barbarians, and everything else became changed, still the old-world system of state religions remained unchanged. The Mohammedans, who broke in from the south-east, have always regarded intolerance as a sacred duty; and the Teutonic tribes, who broke in from the north-east, accepted as a matter of course, along with Christianity, its traditional outward forms. Thus, Clovis (500) established the new religion in his Frankish kingdom; Charlemagne (800) even drove the Saxons to conversion at the point of the sword, and with his 'missi,' or royal commissioners, inspected and managed church affairs throughout his wide dominions; and the English kingdoms, gradually blended into unity, combined in intimate connection the authorities of church and state, without any suspicion that they might one day turn against each other.

But the dangers of such a feeble patchwork of state religions, covering the face of Europe, were obvious and manifold. There was first the insidious danger of 'Simony'—i.e. of a corrupt use of patronage by the laity. Then there was the danger of violent destruction of small state-churches in detail by the fierce and greedy barons of the neighbourhood; and lastly, there was the yet larger peril looming in the future, that each kingdom might finally set up a state religion for itself, and thus hopelessly break up the unity of Christendom. To meet and cope with all these dangers some powerful churchman of large ideas was urgently required, and such a man providentially appeared (1050) in Hildebrand (Pope Gregory VII.). Under his vigorous rule all the existing state religions of Europe were crushed and cramped together into a sort of imperial religion; and for two centuries (till 1300) it seemed as though one all-embracing empire religion were destined to swallow up and destroy all the minor state religions of the world. But when the vast war waged by the papacy in the Crusades had ended in ignominious failure, and when the insensate ambition of men like Innocent III. and Boniface VIII. had roused both France and England to resistance, that great movement of return to state religions (in the proper sense) began which culminated at last in the Reformation. And then the effect of prolonged and obstinate resistance to all change, and of desperate recourse to fire and sword and fraud and treachery, in maintenance of a despotic system in the church which the free strong nations of the north would not endure, was seen in a general break-up of Christendom.

The first thought naturally was to revert to the previous long-tried system of state religion. But when that seemed reduced to an absurdity in the Augsburg settlement (1555) of *cujus regio ejus religio*—making the church an aristocracy instead of a despotism, and every petty duke and count a pope in his own dominions—the tormented nations had recourse to the sword. Germany was torn to pieces and ruined for two hundred years. France

was steeped to the lips in blood, Spain and Austria were silenced, the Netherlands thrown into revolt, and England plunged into her great rebellion, till out of the seething strife between papal religion and state religion there gradually emerged a third form—democratic religion. It began, naturally enough, in Switzerland—at Zurich and Geneva. It permeated and honeycombed, to their ultimate downfall, the despotisms in church and state which ‘concordats’ had conspired to establish; till at last the various acts of toleration in England, the secular ‘Constitution’ of the United States, and the French revolutionary enactments of 1789 and 1830 completed the transformation of every state religion throughout Europe into a congeries of virtually free churches—sometimes with, sometimes without, a survival from the past in the shape of a central establishment fully tolerating all its neighbours. Thus, at the present moment, England (but not, since 1914-20, Wales) and Scotland retain, along with absolute toleration for every other form of religion, modified state churches; while Ireland—like the United States—has none.

The most prominent example of a lately surviving state religion, with intolerance for all other forms of faith, was to be found in Russia, where the Orthodox Greek Church reigned supreme and dissent was severely persecuted. Religious freedom and disestablishment followed the revolution. In Greece there is full toleration, though the state religion is that of the Greek Church. In Italy, ‘by the fundamental law of the kingdom’ in 1870, the state religion is Roman Catholic, but there is now complete toleration for other forms of faith. In Spain the state religion is also Roman Catholic, and toleration is still limited. The Portuguese republic separated church (Roman Catholic) and state. Till of late France recognised Roman Catholics, Protestants, Jews, and (in Algeria) Mohammedans as entitled to state-payment (in very varying proportions); but since 1906 no religious institution is thus recognised. In Belgium the state does not interfere with the internal affairs of any religious body, but it subsidises the Roman Catholics, the Protestants, and the Jews. In Germany there is universal toleration. Under the empire the various states subsidised their religious communities in various ways. The republican constitution declares that there is no state church, but allows the various lands to aid religious bodies as before, pending legislation. In Denmark, Iceland, Sweden, and Norway there is full toleration for all, but the state religion is Lutheranism. In Holland Protestants, Roman Catholics, and Jews are subsidised by the state, but there is toleration for all. In Turkey the state religion is Mohammedanism. In Switzerland there is absolute freedom for every form of faith. The republican constitution of China prescribes no state religion, though it was agreed that national teaching in ethics should be based on Confucianism. On the whole it would seem that the system of state religion is, by the advancing tide of democracy, threatened with extinction; but that some countries retain it, as an axis round which other communions may crystallise, or at least as a security against Atheism, Ultramontan-ism, and other dangers which some fear the future may have in store for democratic states.

The special relation of the church and state in the Jewish theocracy will be gathered from the articles **BIBLE**, **JEW**. The growth of nonconformity in England led to keen controversy between the defenders and the opponents of church establishments; and, especially since the foundation of the ‘Society for the Liberation of Religion from State Patronage and Control’ in 1844, there has been an increasingly outspoken demand for the disestablishment with or without the disendowment of the Church of England, especially (till it was achieved) in Wales. For the ‘Erastian Con-

troversy,’ see **ERASTUS**; for the ‘Bangorian Controversy,’ see **HOADLY**; for the rivalry between the church and dissent in the schools, see **EDUCATION**. The great Scottish ‘Voluntary Controversy’ (see **UNITED PRESBYTERIAN CHURCH**) between the defenders of the church and dissenters was at its height in 1829-34; the Free Church (q.v.) long insisted on the establishment doctrine in a modified form. The disestablishment of the Irish Church (1869) rendered the controversies as to the established churches in the other parts of the United Kingdom more acute. For other controversies bearing more or less directly on the question, see **CATHOLIC EMANCIPATION**, **JEW**s (for the removal of Jewish disabilities), **CHURCHYARDS**, **HOOKER**, **NEWMAN**, **OATH**, **PERSECUTION**, **TEST ACTS**, **TITHES**, **TOLERATION**; and the articles on **Independents**, **Friends**, and other **Nonconformists**, as well as that on the Church of England. Of the British colonies, it may be generally said that those which have representative government have no state church, though provision has long been guaranteed for Catholic education in Quebec province. And in most of the Crown colonies also the disestablishment of the Church of England, and the withdrawal of state aid where there was concurrent endowment, has been carried out, especially since 1868. In India there is a small Anglican establishment for the army and other English residents. In the articles on the several countries notes will usually be found as to whether there is an established church or not. And for the view that the church should finally be merged in the regenerated state, see **ROTHÉ** (**RICHARD**). Of the copious literature, see, of works favourable to establishments, Seiden, *On Tithes* (1618); Coleridge, *Church and State* (1830); Stanley, *Church and State* (1870); Curtis, *Dissent in relation to the Church of England* (1871); Warburton, *Alliance of Church and State*, Maitland, *The Voluntary System* (1837); Moore, *Englishman's Brief for his National Church* (1880); Selborne, *Defence against Disestablishment* (1886); Hughes, *The Old Church and the New* (1891); Story, *The Church of Scotland* (1891); W. H. Abraham, *Church and State in England* (1905). Unfavourable: Locke, *Letters on Toleration* (1689); Wardlaw, *National Establishments* (1839); Baptist Noel, *Church and State* (1849); Vaughan, *English Nonconformity* (1862); Mail, *The Voluntary Principle* (2d ed. 1890); Skelton, *Free Churches* (1869); *Religious Republics* (1869); *The Case for Disestablishment* (1881). Of books on church and state in general, the following may be consulted: De Marca, *De Concordantia Sacrorum et Imperii* (fol. 1641); Franck, *Philosophie du Droit Ecclesiastique* (1864); Zeller, *Staat und Kirche* (1873); Geffcken, *Church and State* (trans. 1877); A. Taylor Innes, *Church and State* (1880); Schall, *Church and State in the United States* (1888); Philimore, *Ecclesiastical Law* (1895); Hon. A. Elliot, *The State and the Church* (2d ed. 1889); *Church Problems*, ed. Hensley Henson (1900). See also **GALLICAN CHURCH**, **NONCONFORMISTS**, **CONCORDAT**.

States-general (Fr. *états généraux*), the name given to the representative body of the three orders (nobility, clergy, burghers) of the French kingdom. In the time of Charlemagne and for seventy years after his death there were assemblies of clergy and nobles held twice a year to deliberate on matters of public importance. There is no trace of any national assembly in France properly so called earlier than 1302, when the States-general or representatives of the three orders were convened by Philip the Handsome in his quarrel with Pope Boniface VIII. The States general, however, though their consent seems in strictness to have been considered requisite for any measure imposing a general taxation, had no right of redressing abuses except by petition, and no legislative power. Under Charles VI. and Charles VII. they were rarely convened. Louis XIII. convoked them, after a long interval, in 1614, but dismissed them for looking too closely into the finances; and from that time down to the Revolution (1789) they were never once summoned to meet. As soon as they did assemble—the clergy, 291; noblesse, 270; *tiers état*, 557 (nearly half lawyers) the Third Estate, after inviting the noblesse and clergy to sit with them, on the advice of Sieyès, constituted themselves

a National Assembly (17th June). About 150 of the clergy joined them (22d June), and nearly 50 of the nobles, with Philip of Orleans, on 25th June; the rest followed by the king's command two days later.

The title *States-general* was likewise borne by the representatives chosen by the provinces of the old republic of the Netherlands to exercise sovereign power. They met at the Hague (1593-1795), and voted by provinces. The name is retained for the existing legislative body or parliament of the kingdom of the Netherlands. See also *ESTATES*.

States of the Church. See *CHURCH* (*STATES OF THE*).

States' Rights, in the history of the United States, refers to a construction of the Constitution and to a doctrine based on that construction, to the effect that the several states of the Union were and are independent sovereigns, federate to attain and maintain certain common interests by means definite and limited, and that to them alone allegiance is due by their citizens; that the general government is not raised by the Constitution to the position of a national sovereign, but is merely a diplomatic agency whose acts must be ratified by the independent states from whom its authority is derived; and that these are each entitled to judge of any infractions of the Constitution, and to nullify any acts of congress which they may hold to be in excess of its authority, or even to secede from the Union. It will be evident that this position rests on a false assumption, for not one of the thirteen colonies which first formed the United States ever possessed an independent sovereignty, nor could sovereignty have been attained by them otherwise than by united action; so that in 1776 it was a single possessor of the entire sum of sovereign powers that came into being in the person of thirteen states manifesting the will and force to hold such power as one national state within all the territory known as the United States; nay, each several state jurisdiction is actually dependent on that federal will and force, and the sovereign powers exercised in the government of each state, as well as those exercised in and for the whole country by congress, are derived from the will and force of all the states, existing as one integral sovereignty. See Dr J. C. Hurd's *Union-State* (New York, 1890).

Invalid as the doctrine appears, however, it has played a prominent part in the country's history, and brought on finally the war of secession. Its earliest appearance was during the troublous years that followed the French Revolution, when the unsettled condition of affairs in that country alarmed congress and led it to pass certain Alien and Sedition laws, authorising the president to remove from the United States aliens whose presence might seem to him of public danger, and to punish sedition and seditious publications. This action of congress appeared to some to overstep its powers, and in 1798 the legislatures of Kentucky and Virginia protested vigorously on States' Right grounds; but the other states dissented from the position thus for the first time formally assumed. In 1811, and again in 1819, the question was raised in connection with the United States Bank Charter, Henry Clay, and afterwards the state of Maryland, maintaining that congress had no power to incorporate companies or to create a bank. So far the advocates of States' Rights had spoken only; in 1832, in South Carolina, they made the first attempt to carry the principle into action (see *NULLIFICATION*); in 1860-61 (South Carolina again the first), and in the years which followed, the seceding states carried out that principle, of which they assumed the truth, to the full. The war of secession was the logical outcome of the disputes and agitation of sixty years; with its failure it

may be presumed that the doctrine which inspired it, at least in its extreme form and as a factor in practical politics, fell too.

Statice. See *PLUMBAGINACEÆ*.

Statics, the branch of dynamics which treats of equilibrium. The ordinary Balance (q.v.) is one of the most important of statical instruments. With it we balance the weight of a body of unknown mass against the combined weights of a number of standard masses, and so determine the unknown mass in terms of recognised units. The general principle of statics is that which describes the condition of equilibrium amongst a number of given forces. The condition is that the vector sum of the moments of the forces about any and every point vanishes. It is more usual in text-books to break this statement up into two, which admit of ready application. The first is that the sum of the components of the forces along each of three non-coplanar directions vanishes; and the second that the sum of the moments of the forces about each of these three directions also vanishes (see *MOMENT*). These two rules give six conditions for the equilibrium of a rigid body, three for translation, and three for rotation. Used in combination with other roots, the word statics always implies equilibrium or relative rest. Thus we have *Hydrostatics* (q.v.) dealing with the equilibrium of fluids, and *Electrostatics* (see *ELECTRICITY*) treating of the equilibrium of electrified bodies. See also *DYNAMICS*. Minchin's *Statics* is the standard English treatise on the subject. See also *GRAPHIC STATICS*.

Stationers' Hall, the hall of the 'Master and Keepers or Wardens and Commonalty of the Mystery or Art of the Stationers of the City of London.' The Company was incorporated in 1557, and had until the passing of the Copyright Act in 1842 an absolute monopoly, as all printers were obliged to serve an apprenticeship to a member of the Company, and every publication, from a Bible to a ballad, was required to be 'Entered at Stationers' Hall.' This registration is no longer compulsory, but is still useful in making good claims of Copyright (q.v.). The series of registers, commencing in 1554, is of enormous value in the history of English literature; see *Arber's transcripts* (from 1554 to 1640, 5 vols.), and the *Roxburghe Club's* (1640 to 1708, 3 vols.). Before the days of printing, the stationer, like the Roman *statimarius*, was the copyist or transcriber of MSS., or the man who had them copied for him; and as *stationarius* was often also *librarian* or bookseller, the stationer at the invention of printing was often printer, publisher, and bookseller in one (see T. G. Law's *Collected Essays*, 1904).

Stationery Office, an office established in 1786 to provide books, stationery, &c., for the government offices at home and abroad; but its main function is in making contracts for the printing of all reports and other matters laid before the House of Commons. There are branches in Edinburgh and Manchester.

Station Island. See *DERG* (*LOUGH*).

Stations (Lat. *statio*), a name applied in the Roman Catholic Church to certain places reputed of special sanctity, which are appointed to be visited as places of prayer. The name is particularly applied in this sense to certain churches in the city of Rome, which, from an early period, have been appointed as churches which the faithful are particularly invited to visit on stated days. The names of these churches are found on the several days in the Roman missal prefixed to the liturgy peculiar to the day. The word, however, is employed in a still more remarkable manner in reference to a very popular and widely-received

devotional practice of the Roman Catholic Church, known as that of 'The Stations of the Cross.' This devotion prevails in all Catholic countries; and the traveller often recognises it even at a distance by the emblems which are employed in directing its observance—the lofty 'Calvary' crowning some distant eminence, with a series of fresco-pictures or bas-reliefs arranged at intervals along the line of approach. But the same series of images or pictures is ranged round most Roman Catholic churches, usually starting from one side of the high altar and ending at the other. These representations, the subjects of which are supplied by scenes from the several stages of the Passion of our Lord, are called Stations of the Cross, and the whole series is popularly known as the *Via Calvarii*, or Way of Calvary. The origin of this devotional exercise, like that of local pilgrimages, is traceable to the difficulty of access to the Holy Places of Palestine, consequent on the Moslem occupation of Jerusalem and the Holy Land; these representations being designed to serve as some analogous incentive to the piety and faith of the Christian worshipper of our Lord in His Passion. The number of the so-called 'stations' is properly fourteen, although in some places fifteen, and in others, as Vienna, only eleven; but, whatever may be their number, the subject of all is a sort of pictorial narrative of the Passion. The devotional exercise itself is performed by kneeling at the several stations in succession, and reciting certain prayers at each. Forms of prayer are prescribed to those who can read. The poor and ignorant recite the Lord's Prayer and Hail, Mary! all being directed to fix their thoughts in grateful memory upon 'the sufferings which each representation describes our Lord as having undergone, in atonement for the sins of mankind.' Many 'indulgences' are granted to those who, having duly repented of their sins, shall piously perform this exercise. One Anglican church at least, that of Framme in Somerset, has sculptured Stations of the Cross.

Statistics, that branch of Political Science which has for its object the collecting and arranging of facts bearing on the condition, social, moral, and material, of a people. The collecting of such facts, and the taking of censuses for military purposes, have been in use since the earliest times: King David numbered his people, and Egyptians and Romans had censuses. But the treatment of the statistics of all nations as a branch of study dates from the time of Comring (1606-81), in Germany, to whose distinguished successor Achenwall of Göttingen (1719-72) the name of the study (Ger. *Die Statistik*) seems to be due. As distinguished from the early and simple 'descriptive statistics,' in which the figures were but illustrations to the text, a more scientific arithmetical or mathematical method may be credited to Süssmilch (1707-67), whose work had been simplified by the working out of probabilities and averages in connection with mortality tables and otherwise, by Petty and Halley in England, and others. But most of all to Quételet (q.v.), the great Belgian statistician, is the science indebted for its present standing. The principle lying at the foundation of the science as ultimately developed is that the laws which govern nature, and more especially those which govern the moral and physical condition of mankind, are constant, and are to be discovered by the investigation and comparison of phenomena extending over a very large number of instances. Accidental diversities tend to neutralise each other, their influence diminishing as the area of investigation increases; and if that area be sufficiently extended, they so nearly disappear that we are entitled to disregard them altogether. While the length of a single life cannot be counted on, an average of

1000 or 10,000 lives gives us a constant quantity, sufficiently near the truth to answer the purposes of insurance companies. Even the acts which are the most purely voluntary as regards individual men have been found to be subject to laws which, in respect of the masses which make up society, are invariable in like circumstances, and discoverable.

The science of statistics has a twofold relation to political and social economy. The facts collected by the statist are the bases on which political economy rests; their application to social and economical problems is an appeal from imagination to fact. But the statist must be guided by the political economist in what direction to extend his investigations; without political economy we should have had no statistics. There have been keen and useless controversies as to whether statistics is an adjunct to other sciences, and a mere method, or an independent science; and as to whether it should limit its scope to national and social phenomena (in which acceptance the word 'demography' has been proposed as a descriptive name), or should be extended into meteorology and other natural sciences. It is impossible to give any convenient and comprehensive classification of the multifarious topics that fall within the sphere of the statistician—population, trade inland and foreign, wealth, currency, prices, banks, social conditions, the people, &c.

There was a kind of statistical bureau in France in Sully's days; such an institution was permanently set agoing in 1800. But the perfecting of statistical methods owes more to the foundation of the Belgian statistical bureau under Quételet in 1831. Since then most civilised lands have devoted much time, labour, and money to collecting and tabulating their statistics—France, Italy, and Germany, and the United States being perhaps remarkable for the fullness and systematic organisation of their statistical returns. What is done in England is not managed by any one central bureau or board, and is less systematic, though very varied and valuable (see BLUE-BOOKS).

There was a statistical section added to the British Association in 1833, and the Statistical Society of London was established in 1834. Under Quételet's influence a great statistical congress was brought together at Brussels in 1853, and many like congresses have been held since. The International Institute of Statistics was founded in 1885.

Quételet's influence has also been felt in biology, along with that of Galton, Karl Pearson, and W. F. R. Weldon. The three last named founded the periodical *Biometrika* in 1902. Results of statistical study of variation are already valuable, and promise much.

See CENSUS, MORTALITY (BILLS OF), INSURANCE, GRAPHIC METHODS, AVERAGE, PROBABILITIES, HEREDITY (for Mendelism); annuals like the *Almanach de Gotha*, *Statesman's Year-Book*, and such almanacs as Whitaker's; Millhall's *Dictionary of Statistics*; Kolb's *Condition of Nations* (Eng. trans. 1880); Hubner's *Statistische Tafel*; Webster's *Trade of the World* (1880); Block's *Traité Théorique et Pratique de Statistique* (1878); and other works and articles about statistics by statisticians like Bodio, Haushofer, Knies, Gabaglio, Farr, Giffen, Rawson, Mayo Smith, Von Mayr, Tiesse (1905). There are short works by Bowley (1921) and Edlerton (1910).

Statius, ACHILLES. See ACHILLES TATIUS.

Statius, PUBLIUS PAPINUS, Roman poet, was born at Naples 40 to 45 A.D., son of a poet and schoolmaster at Naples and at Rome. From early youth addicted to poetry, he gained prizes in the contests at Naples, won the Alban olive-wreath three times, and flourished as a court poet in the favour of Domitian, whom he flattered almost as shamelessly as his rival Martial himself. He lost

the wreath of oak-leaves at the Capitoline competition in 94, and thereafter retired to Naples with his wife Claudia, where he died about 96. His chief work is the *Thebais*, an epic in twelve books on the famous theme of the struggle between the brothers Eteocles and Polyneices of Thebes. The poem took twelve years to write, yet its construction is slovenly enough—one episode alone occupying one-sixth of the whole poem. It is tedious as a whole, and marred by over alliteration and allusiveness, but is redeemed by passages of exquisite art. Of another epic, the *Achilleis*, only a fragment consisting of one book and part of another remains. His *Silvae*, or occasional verses, apparently half improvisations, are thirty-two in number, extending to nearly 4000 lines, mostly in hexameters. They have the freshness and vigour, together with the artistic imperfections, of unpremeditated effort, but, putting aside the flatteries to the emperor, they show not seldom a spark of the right Promethean fire. The quick touches of pathos, on separation and death, and on the sweet charm of childhood, would alone preserve some of these slight poems from oblivion.

The *editio princeps* of the epics appeared in 1470, of the *Silvae* in 1472. Throughout the middle ages the fame of Statius was great, as readers of Dante (*Purg.* xxi.) will remember. Markland, O. Müller, Kohlmann, Baehre, and Postgate (*Corpus Poetarum Latinarum*, Fasciculus iv 1904) have been amongst his editors. D. A. Slater translated the *Silvae* (1908), with introduction.

Statuary. See SCULPTURE.

Statute of Frauds. See FRAUD.

Statutes express the will of the legislature, and take effect from the first moment of the day of passing. Except in Scotland, a statute remains in force though obsolete; and when repealed it is not revived by the repeal of the repealing act. It is always to be construed 'according to the intent of them that made it.' Primarily, technical words are understood in their technical, other words in their popular sense. When precise and free from ambiguity, they receive their literal meaning and grammatical construction, whatever may be thought of the wisdom or policy of the enactment. But language is so imperfect, and general words are so elastic and open to such varieties of meaning and force, that the literal construction often does not express the real intention. Where such a doubt arises it is necessary to consider what was the earlier law, what its defect, and what the proposed remedy and its object; in other words, to examine the history of the act and the context. The whole act is read, every part in the sense best harmonising with the rest. The preamble is especially invoked to explain what is doubtful. Earlier acts, though expired or repealed, and even later ones on the same or analogous subject, are resorted to, also, for light. All statements of members of the Houses and draftsmen as to what was intended are disregarded; but the rule that the title, marginal notes, and punctuation are to be disregarded has, as regards the title, become obsolete, and as regards the marginal notes, is now of imperfect obligation.

The scope and object of the act being thus ascertained, it generally receives a beneficial construction which best 'suppresses the mischief and advances the remedy.' Sometimes words receive an unusual stretch of meaning; for instance, a married woman living apart from her husband would be included in the expression a 'single woman,' where the object of the act was to give the mother of an illegitimate child a claim on the father for its support. So a generic term usually includes species which did not exist when the act was passed. Thus, an act of George II. against

copying copyright engravings includes photographic copies, and one of William IV. against 'furious driving' applies to bicycles, though photography and bicycles were not then known. In the same spirit all devices resorted to for evading a law, or misusing powers which it conferred, are defeated by including such attempts within it.

To give effect to the intention expressions are sometimes strained; for instance, 'beyond the seas' is read in an old act as equivalent to 'out of the British dominions.' Sometimes the collocation of the words is altered, or they are rejected altogether, or even words are interpolated. But such modifications are made only when obviously necessary in correction of a careless text which did not make sense or was incomplete as it stood.

Beneficial construction is applied less freely to penal acts. There is a reluctance to supply in them the defects of language, or to eke out their meaning by doubtful inferences. Where a word or phrase is open to reasonable doubt, the benefit of the doubt is given to the subject. An omission, also, would probably not be supplied; but the extreme strictness of construction of former times has now materially given way to the paramount rule that a statute is to be expounded according to the real intention. Acts which impose on the subject burdens or formalities, or otherwise restrict natural liberty, or create monopolies, or confer privileges are construed in the same spirit as penal acts. The language of local and personal acts, which invest persons or bodies with rights and privileges for their own profit or interfere with the rights of others, is regarded as rather that of its promoters than of the legislature, and is consequently construed most strongly against them.

Certain constructions are always rejected, if the language can admit it. Any which would lead to inconvenience and injustice or absurdity would be avoided as probably foreign to the real intention. For this reason a construction which made an act operate retrospectively on vested rights would be avoided; and so would any which conflicted with international law—a construction, for instance, which extended a criminal statute to a foreigner for an offence committed abroad. Again, an act would not be read as affecting the prerogative rights or property of the crown, unless the intention was plainly expressed or irresistibly inferable. A like reluctance is felt to attribute an intention to onst the jurisdiction of the superior courts, or to extend that of new or inferior tribunals and authorities.

If two statutes, or two passages in one, are contradictory, the earlier is abrogated by implication. But, as self-contradiction was probably not intended, such a construction is rejected unless inevitable, or unless there be inconvenience or incongruity in both enactments being in force, or the later would be inoperative if the earlier was not repealed. Special and local acts are unaffected by general acts inconsistent with them, being regarded as not in the contemplation of the legislature when making the general act.

Another and most important axiom is that no change of the law is intended beyond the specific object immediately in view. Words and phrases, therefore, however comprehensive literally, are so restricted as not to affect any general principles of law. An act, for example, which empowered 'any' justice to try a case would not include a justice who was incapacitated by interest or otherwise from trying it. To confine an act to its immediate object, it is often construed as operative only between certain persons, or under certain circumstances, or for certain purposes only. Thus, an act which made a bill for money lost at

play 'void to all intents and purposes' would not affect the validity of the bill in the hands of an innocent indorsee for value, but would apply to it only when in the hands of the drawer or of others with no better title.

It follows that incidents are sometimes found imported into an act which give it an operation different from its strictly grammatical meaning. Thus, where a power is conferred, everything in the way both of right and obligation which is indispensable to its due exercise is tacitly included by law. When, therefore, a statute enacts that a public officer 'may' do some act of a judicial or public nature, it also by implication directs that he 'must' exercise the power whenever the occasion arises; and if its exercise may prejudice a person, it involves the further duty of first giving the latter an opportunity of being heard against it.

When a statute grants a right subject to certain formalities, compliance with such prescriptions is essential on pain of invalidation. But when the prescriptions relate to a public duty, and invalidation for neglect would be unjust to persons who have no control over the defaulting official, without promoting the object of the act, non-compliance does not invalidate. In the former case the act is imperative, in the latter directory only. A penalty for doing something implies a prohibition; this makes the prohibited act unlawful; and all contracts connected with illegal acts are void.

There are some minor rules of interpretation which hardly call for notice here. Some will be found in the Act 52 and 53 Vict. chap. 63. But it may be mentioned, in conclusion, that usage, or a long and general public or professional practice, sometimes impresses on an enactment a meaning not in accord with the natural sense of the words, which is nevertheless accepted as conclusive.

Staubach. FALL OF. See LAUTERBRUNNEN.

Staunton, capital of Augusta county, Virginia, in the Shenandoah valley, 96 miles WNW. of Richmond. It is the site of the state lunatic and deaf and dumb and blind asylums, and contains several women's schools, large ironworks, and flour and planing mills. Pop. 10,600.

Staunton, HOWARD, chess-player and Shakespearean scholar, was born in 1810, studied at Oxford, early settled down to journalism in London, and died June 22, 1874. His victory in 1843 over M. St. Amant made him the champion chess-player of his day. To this subject he contributed the following works: *The Chess player's Handbook* (1847), *Chess player's Companion* (1849), *Chess tournament* (1851), *Chess Praxis* (1860). His edition of Shakespeare (1858-60) offered a number of textual emendations so excellent as to give him rank among the best critics of that time. It was enriched by 824 illustrations by Sir John Gilbert. Staunton also published an edition without illustrations, and in 1866 a careful photo lithographic fac-simile of the first folio text of Shakespeare.

Staupitz. JOHANN VON, friend of Luther (q.v.).

Staurolite (Gr. *staurus*, 'a cross'; *lithos*, 'a stone'), a silicate of alumina with ferrous oxide, magnesia, and water, crystallises in orthorhombic forms, and often occurs as twinned cruciform crystals in certain gneisses and schists. It is reddish, yellowish brown, or brownish black.

Stavanger, the most important town in the south west of Norway, stands on the southern side of Bukken Fjord, 100 miles S. of Bergen. It has

two harbours, and derives its importance from its connection with the fisheries of the adjacent coast. The town dates back to the 9th century at least, but has been frequently destroyed by fire, and is now quite a modern place. The cathedral, a Gothic structure, was founded by an English bishop (Reinald) in the 11th century, but was restored in 1866. The bishopric was revived in 1924. Stavanger has become a favorite rendezvous of tourists. Pop. (1920) 43,778.

Stavesacre (*Delphinium Staphisagria*), a species of Larkspur (q.v.), a native of the south of Europe. The seeds which contain the alkaloids delphinine, delphinoidine, and delphisine, and a considerable quantity of a fixed oil, are poisonous. From them an ointment is made which is used to kill lice.

Stavropol, a town of Russia in the North Caucasian Area; pop. 64,000.

Stead. WILLIAM THOMAS (1849-1912), son of a Congregational minister at Howdon-on-Tyne, became editor of the *Northern Echo* at twenty-two, and assisted and succeeded Lord Morley as editor of the *Pall Mall Gazette*. He was a public spirited, audacious, and influential journalist, and suffered imprisonment for well-meant indiscretion in promoting social purity. He retired from the *Pall Mall* in 1889 to found the *Review of Reviews*, which became the organ of his independent and sometimes puzzling views in religion, ethics, and politics; and he carried on also a spiritualist paper. He perished in the *Titanic* disaster. See Life by his daughter (1913), and by F. Whyte (1925).

Stealing. See THEFT.

Steam is the vapour of water; when dry it is invisible and transparent like air. The formation of steam is naturally enough connected popularly with a high temperature, but the two things do not necessarily go together. In the open air water will evaporate slowly at any temperature lower than that at which it boils. The only limit to such a process is when the air in contact with the water is already saturated with water vapour of the maximum density which the water can give off at the existing temperature. Though this vapour pressure is necessarily lower than the air pressure, the vapour given off passes away by diffusion, the air pressure remaining unchanged.

The properties of steam are most conveniently studied by consideration of what takes place when steam is generated under constant pressure. Suppose we have a long vertical cylinder fitted with a piston moving freely but steam tight in the cylinder, and that we can load this piston so as to maintain a steady pressure on any fluid below the piston, and that we introduce one pound of water into this cylinder below the piston, and apply heat to the bottom of the cylinder. This heat will, if its application is continued long enough, produce the following three effects:

(a) The temperature of the water will rise steadily from its initial value of t_0 till a temperature t is reached, the value of t depending on the pressure p exerted by the piston, the substance still remaining water; the heat so expended is termed *sensible*.

(b) At the conclusion of the first stage the water begins to evaporate, the temperature remaining steady at t , and as a result the piston will rise, since the volume occupied by the steam is greater than that of the original water. This process will go on till all the water has been turned into vapour, which is termed *saturated steam*. The heat which has been absorbed during this stage, since it produced no change in temperature, is termed *latent*.

(c) If the application of heat is continued, the

volume of the steam and its temperature will increase, the pressure remaining unchanged, and the steam is now termed *superheated*.

Briefly the difference between saturated and superheated steam may be explained in the following manner—when water at the temperature of the steam is added to a mass of superheated steam some of this water would at once be converted into steam, but if the water had been added to a mass of saturated steam it would remain quite unaffected. Any vapour which is in contact with the liquid from which it was formed is necessarily saturated, and in this condition it usually differs considerably in its properties from those of a perfect gas; on the other hand superheated steam begins more and more, as the temperature of superheat is increased, to approximate in its properties to those of a perfect gas.

The factors we require to consider in regard to steam are the temperature, the specific volume, or volume of one pound, and the quantity of heat required per pound in its generation, and the way in which these three quantities change in value as the pressure at which the steam is formed is varied.

Saturated Steam.—Relation of temperature and pressure. The variation of temperature with change in pressure was experimentally determined by Regnault (*Mém. Inst. France* 1847, vol. xxi.); the following table gives the values of t for pressures varying from 0.5 to 200 lb. per sq. inch, as calculated by Callendar; his results agree closely with those experimentally determined by Regnault.

PROPERTIES OF SATURATED STEAM.*

Pressure lb. per sq. inch	Temperature Centigrade	Volume Cub. ft.	L	H
0.5	26.4	640.5	26.3	580.4
1.0	28.7	335.4	38.9	373.8
14.7	100.0	26.79	100.0	339.3
20	103.9	20.08	109.0	323.9
30	121.3	13.74	121.5	326.0
40	130.7	10.50	131.0	319.9
60	144.8	7.18	145.5	310.7
80	155.5	5.40	156.6	302.6
100	164.3	4.19	165.7	296.1
140	178.3	3.25	180.4	285.8
180	189.5	2.56	192.3	276.2
220	198.9	2.12	202.3	268.4
240	206.0	1.81	211.2	261.3

* This table is extracted by kind permission of Prof. Callendar and the publishers, from *The Callendar Steam Tables*, published by Messrs Edward Arnold & Co. in 1915.

An inspection of this table will show that the pressure of steam increases at a far higher rate than the temperature, doubling the temperature say from 100° to 200° C. increases the pressure nearly 15 fold. This is a matter of extreme importance in the use of steam for generating power, since the thermal efficiency of the motor depends primarily on the range of temperature available, while the amount of the steam pressure is of vital importance in the design of the boiler.

Relation of temperature and specific volume.—It is very difficult to determine this relation by direct experiment, though some very reliable experiments have been made, notably those at the Technical High School, Munich. The figures for the specific volume of steam given in modern steam tables are based upon the characteristic equation of Callendar; by the use of this equation and certain others derived from it, and by utilising at the same time certain experimental results, Callendar was able to calculate both the specific volume and the amount of heat expended in the formation of saturated steam under any given temperature conditions.

The characteristic equation is $V = \frac{RT}{P} + b - c$;

in this equation T is the absolute temperature centigrade of formation, P is the pressure in lb. per square foot, R and b (co-volume) are constants,

and c (co-aggregation) is a term which varies inversely with a certain power of T . If steam were a perfect gas this equation would be $V = \frac{RT}{P}$; the

other two terms are necessary to express the way in which the specific volume of dry steam (whether saturated or superheated) varies from the ideal volume it would occupy if it were a perfect gas. In the table above, the values given for V are those obtained from Callendar's equation. For approximate results, and when steam tables are not available, the formula $PV^{1.4} = 490$ may be employed to find the volume in cubic feet of 1 lb. of saturated steam under any given pressure P measured in lb. per square inch.

The pressure-gauges of boilers always give the pressure of the steam, in pounds per sq. inch above the atmosphere; in the steam tables the pressures are always absolute, hence it is necessary to add to the gauge pressure the atmospheric pressure at the instant in question, as obtained from a barometer reading taken at the same time; the pressure per square inch corresponding to the standard atmosphere is very nearly 14.7 lb.

Heat units required to generate steam under constant pressure. It is convenient to take as the unit of heat quantity the *pound-calory*, that is the amount of heat needed to warm 1 lb. of water 1° C.; this quantity, however, varies slightly with different initial temperatures of the water, since the specific heat of water is not constant; it diminishes slightly from 0° C. to 35° C., and thereafter increases continuously. The unit is therefore sometimes taken as the heat needed to warm 1 lb. of water 1 degree at some definite temperature, say 15° C.; or we may take as the unit of heat one-hundredth of the whole heat needed to warm 1 lb. of water from 0 to 100° C. under a constant pressure of 14.7 lb. per square inch.

In the first stage of the process of generating steam under constant pressure, that is, the stage during which the liquid is being warmed from its initial temperature to that at which the steam begins to form, the heat needed in pound calories is very nearly equal numerically to the difference between these two temperatures, that is, it is nearly equal to $t - t_0$. It is always a little greater than this owing to the fact that the specific heat of water increases continuously from 35° C. upwards; the values for this sensible heat h given in the table allow for this change in the value of the specific heat. Since the volume of the water has increased by an exceedingly small amount during this rise of temperature, most of this heat has gone in increasing the stock of internal energy possessed by the water.

In the second stage, during which the steam is generated and the temperature remains constant, a large amount of heat is supplied, and since it does not change the temperature it is called the latent heat of evaporation and is denoted by the symbol L . For steam generated at 100° C. it is per lb. of steam 539.3 pound-calories, or more than five times the heat needed to warm the lb. of water from 0° to 100° C. As the temperature of evaporation increases from 0° C. upwards, the quantity of latent heat required steadily diminishes; values of L are given in the table. A certain proportion of this latent heat has gone in doing external work, since the volume occupied by the steam is much greater than that originally occupied by the water from which it was formed, and this change of volume has been against a constant steady resisting pressure. Expressed in pound-calories the external work done is $= \frac{P(V_1 - V_2)}{1400}$, where P is the constant pressure in lb. per square foot,

and V_s and V_w the volumes in cubic feet occupied respectively by 1 pound of steam and 1 pound of water at the given temperature. The remainder of the latent heat has gone in increasing the stock of internal energy of the substance. The total heat of formation under constant pressure of a pound of dry saturated steam from a pound of water at any initial temperature is therefore $= h + L$.

If we now, by the addition of further heat, change the steam from the saturated to the superheated state, the amount of heat expended will be equal to the rise of temperature, as shown by a thermometer, multiplied by the mean specific heat of the steam, or in symbols, the pound-calories expended per pound of steam will be $k_s (t_s - t)$, where t is the temperature of saturation, t_s the temperature to which the superheat is carried, and k_s the mean specific heat of steam for the range of temperature in question. The specific heat of steam is not constant; the mean values for temperatures of superheat used in modern steam engines vary from about 0.48 to 0.59; the higher values occur when the temperature of saturation from which the superheat begins is high, that is from 180° to 200° C.

Hitherto we have considered only dry-saturated or superheated steam; few boilers, however, which have not been equipped with superheaters supply absolutely dry steam; from this and other reasons in any engine-cylinder the working substance is usually a mixture of water and steam, and the relative proportions of the two are constantly changing. The dryness of wet steam, which is in thermal equilibrium, that is, when the temperatures of steam and water are the same, is measured by the fraction of dry steam present in each pound of the mixture and is denoted by the symbol q . It is an easy matter to calculate the values of the volume, latent heat, &c., of such wet steam; the volume of 1 lb. will be $= qV_s + (1 - q)V_w$, the latent heat $-qL$, and so on.

In thermodynamic problems it is useful to know the total heat in a pound of steam, a quantity Ewing denotes by the symbol I . (In Callendar's tables it is denoted by the symbol H , which must not be confused with the same symbol H as used by Rankine in a different sense.) The total heat is equal to the total internal energy plus the external work which has been done in the process of formation; in calculating the value of I , the internal energy of the water at 0° C under a pressure equal to the vapour pressure at 0° is considered to be zero, and the external work being an extremely small quantity is also treated as zero for these conditions, hence the total heat of 1 lb of water at 0° C. is taken as 0. For any given temperature the total heat of 1 lb. of steam is equal to the total heat of formation of the steam

under constant pressure from 0° plus $\frac{PV_0}{1400}$, where

P is the constant pressure under which the steam has been formed in lb. per sq. foot, and V_0 is the volume of 1 lb. of water at 0° C. This quantity $\frac{PV_0}{1400}$ is always small numerically; for example,

when $P=200$ lb. per sq. inch, it is equal to 0.33 pound-calories.

In the table above, the column headed H gives the total heat of 1 lb. steam, and the column headed h the total heat of 1 lb. water; the difference, therefore, of these two columns gives the latent heat of the steam.

Whenever steam passes from any one condition to another, the gain or loss of heat in the process may be determined by the equation: Heat taken in = increase of internal energy + external work done; any of the three terms may be negative.

Expansion of Steam.—If the process is isothermal the steam must, during the whole process, be in contact with water, that is, in the wet state; in other words, during expansion when it is isothermal, evaporation must be proceeding, and in compression condensation must occur. If, on the other hand, initially dry steam is expanded adiabatically, that is, without taking in or giving out heat, some of the steam is condensed. Since the pressure and the temperature both fall, and as the steam which remains is in a saturated state, the relations between pressure and temperature are precisely those we have shown above to exist for saturated steam.

The dryness of the steam at any point in an adiabatic expansion can be calculated from the formula

$$q_0 = \frac{T_0}{T_s} (q_1 \frac{L_1}{T_1} + \log \frac{T_1}{T_0})$$

where the suffix $_0$ indicates the initial steam conditions, and the suffix $_1$ the final conditions.

Steamboat Springs, a town of Colorado, U.S.A., 110 miles north-west of Denver. Coal, metals, petroleum, onyx-stones, and hot and cold springs are found locally, and there is a considerable agricultural and lumbering industry. Pop. 1200.

Steam-crane. See CRANE.

Steam-engine, a machine, employing steam as the working agent, in order to convert heat energy into useful work. Some of the heat supplied to the machine is transformed into work, and the rest of the heat is rejected as heat at the end of the cycle. Coal or oil burnt in the furnace of a boiler supplies the heat which converts the water supplied to the boiler into steam; the steam then passes into the engine; in the engine the steam, by change of volume during expansion, does work, and after this it passes away into the atmosphere in non-condensing engines, or in condensing engines into a condenser, where by the action of cold water it is again reduced to water. The thermal efficiency of a steam-engine is measured by the ratio of the heat it transforms into work to the total heat it receives from the boiler in a given interval of time. The mechanical efficiency of a steam-engine is the ratio of the useful work the machine gives out to the total work done in the cylinder by the steam during any definite interval of time. Steam-engines in their infancy were known as 'fire' (i.e. *heat*) engines; and in point of fact the older term is the more correct, because the water or steam is only used as a convenient medium through which the form of energy which we call heat is made to perform the required mechanical operations. In modern engines sufficient heat is added to the steam to raise it to a very high pressure, and the excess of this pressure over the pressure opposed to it (either atmospheric pressure or the still lower pressure in a condenser) is both the cause and measure of the work done by the engine. In earlier machines, however, the steam was raised only to atmospheric pressure, and admitted into the engine only to be at once condensed by a jet of cold water. The excess of the atmospheric pressure above the pressure in the partial vacuum caused by the condensation was then the direct cause of work. Engines of this kind were called *atmospheric engines*.

The invention of steam as a moving power is claimed by various nations; but the first extensive employment of it, and most of the improvements made upon the steam-engine, the world indisputably owes to Britain and the United States.

Among the first notices we have in England of the idea of employing steam as a propelling force, is in *The Art of Gunnery* (1647), by Nat. Nye, mathematician; in which he proposes to 'charge a

piece of ordnance without gunpowder,' by putting water instead of powder, ramming down an air-tight plug of wood, and then the shot, and applying a fire to the breach 'till it burst out suddenly.' But the first suggestion of the use of steam in a more or less practical manner was that of the Marquis of Worcester. In his *Century of Inventions*, the

a steam-apparatus by which he claimed to raise a column of water to the height of 40 feet. A machine, of which no accurate description survives, under the name of 'Fire-waterwork,' appears actually to have been at work at Vauxhall in 1663-70. Sir Samuel Morland in 1683 submitted to Louis XIV. a project for raising water by means of steam, accompanying it with ingenious calculations and tables. The first patent in Britain for the application of steam-power to various kinds of machines was taken out in 1698 by Captain Savery. In 1699 he exhibited before the Royal Society a working model of his invention. His engines were the first used to any extent in industrial operations; they seem to have been employed for some years in the drainage of mines in Cornwall and Devonshire. He employed one vessel for the generation of the steam, and two other vessels in which the steam did its work, following in this respect the plan outlined by della Porta in his treatise on pneumatics, published in 1601. He made use of the condensation of steam in a close vessel to produce a vacuum, and thus raise the water to a certain height, after which the elasticity of steam pressing upon its surface was made to raise it still further in a second vessel.

In all the attempts at pumping engines hitherto made, including Savery's, the steam acted directly upon the water to be moved without any intervening part. To Denis Papin (q.v.), a French physicist, is due the idea of the *piston*. It was first used by him in a model constructed in 1690, where the cylinder was still made to do duty also as a boiler; but in an improved steam-pump invented about 1705 he used the piston as a diaphragm floating on the top of the water in a separate vessel, or cylinder, and the steam, by pressing on the top of it, forced the water out of the cylinder at the other end.

The next great step in advance was made about 1705 in the 'atmospheric' engine, conjointly invented by Newcomen (q.v.), Cawley, and Savery. This machine (fig. 1) held its own for nearly seventy years, and was very largely applied to mines. In it the previous inventions of the separate boiler and of the cylinder with its movable steam-tight piston are utilised, although in a new form. The 'beam' was used for the first time, and for the first time also the condensation of the steam was made an instantaneous process, instead of a slow and gradual one. Newcomen's engine was chiefly used, like all former steam-engines, in raising water. To one end of a beam moving on an axis, *I*, was attached the rod, *N*, of the pump to be worked; to the other the rod, *M*, of a piston, *P*, moving in a cylinder, *C*, below. The cylinder was placed over a boiler, *B*, and was connected with it by a pipe provided with a stopcock, *V*, to cut off or admit the steam. Suppose the pump-rod depressed, and the piston raised to the top of the cylinder—which was effected by weights suspended at the pump-end of the beam—and that the steam-cock being open the cylinder was full of live steam, the steam-cock was then turned to cut off the steam, and a dash of cold water was thrown into the cylinder by turning a cock, *R*, on a water-pipe, *A*, connected with a cistern, *C'*. This condensed the steam in the cylinder, and caused a vacuum below the piston, which was then forced down by the

pressure of the atmosphere, bringing with it the end of the beam to which it was attached, and raising the other along with the pump-rod. The cock was then turned to admit fresh steam below the piston, which was raised by the counterpoise and thus the motion began anew. The opening and shutting of the cocks was at first performed by an attendant, but subsequently a boy named

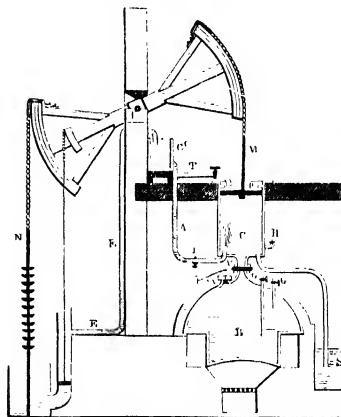

Fig. 1.

Humphrey Potter (to save, it is said, the trouble of personal superintendence) devised a system of strings and levers by which the engine was made to work its own valves. In 1718 Henry Beighton, an F.R.S., invented a simpler and more scientific system of 'hand-gear,' which rendered the engine completely *self-acting*. During the latter part of the time that elapsed before Watt's discoveries changed everything Smeaton brought Newcomen's engine to a very high degree of perfection. As the result of study and experiment he made many improvements in it, in the form of the boiler, the proportions of the cylinder, &c. It was he, too, who invented the *cataract*, a very ingenious self-acting valve arrangement, which is still used in Cornish engines. Though a great improvement as compared with the Savery engine, Newcomen's engines were still extremely wasteful of fuel. In 1725 Leupold invented an engine in which steam of a higher pressure than that of the atmosphere was employed in the cylinder, but his engine possessed defects that prevented its practical use.

The next essential improvements on the steam-engine were those of Watt, which began a new era in the history of steam-power. The first and most important improvement made by Watt was the separate condenser and air-pump, patented in 1769. He had observed that the jet of cold water thrown into the cylinder to condense the steam necessarily reduced the temperature of the cylinder so much that a great deal of the steam flowing in at each upward stroke of the piston was condensed before the cylinder got back the heat abstracted from it by the spurt of cold water used for condensing the steam in the cylinder. The loss of steam arising from this was so great that only about one-fourth of what was admitted into the cylinder was actually available as motive-power. Watt therefore provided a separate vessel in which to condense the steam, and which could, by means of the air-pump, be kept constantly in

a state of vacuum, without the loss which arose when the cylinder itself was used as a condenser. This device, which now looks simple enough, was the greatest of Watt's inventions, and forms the foundation of his fame. His genius was such that in a few years he changed the steam-engine from a clumsy, wasteful, almost impracticable machine into a machine practically the same as that which we now have. The principal improvements since his time have been either in matters relating to the boiler; in details of construction consequent on our increased facilities, improved machinery, and greater knowledge of the strength of materials; in the enlarged application of his principle of expansive working; or in the application of the steam-engine to the propulsion of carriages and vessels. His principal inventions were: (1) The condensation of steam in a vessel separate from the cylinder, so as to avoid the cooling of the latter; (2) the use of a pump, called an 'air-pump,' to withdraw the condensed water and mixed steam and air from the condenser; (3) the surrounding of the cylinder with a steam-jacket, in order to prevent loss of heat from condensation (these three, with others, were included in the specification of 1769); (4) the use of the steam expansively in the way explained further on in this article (this was invented before 1769, but not published till 1782); and (5) the now universally used double-acting engine, and the conversion of the reciprocating motion of the beam into a rotary motion by means of a crank (both these were invented before 1778, the engine being patented in 1782, the crank having before that date been pirated and patented by another). In 1784 Watt also patented and published his parallel motion, throttle-valve, governor, and indicator; all four of which are in substance still used.

The common mode of employing steam in an engine is by causing it to press alternately on the two surfaces of a movable diaphragm or piston enclosed in a fixed, steam-tight, cylindrical box. In fig. 2 A is the piston and B a section of the box. The piston, by means of a rod, E, passing through the end of the box, is made to communicate motion to the rest of the machinery. The steam is first admitted to one end of the cylinder through an opening or 'port,' D, and forces the piston along to the other end.

The current of steam from the boiler is then allowed to pass into the other end of the cylinder through the opening C, and forces the piston back again to its original position, and so on. But it is obvious that while this return-motion is going on the steam previously admitted at D must be allowed some exit, or the piston could not be forced back. The manner of this exit constitutes the difference between the two principal classes of engines, according as the steam is allowed simply to rush out into the atmosphere or is conducted into a separate vessel, and there 'condensed.'

The simplest way in which steam can be used in a cylinder is at the same time the most wasteful. It consists in filling each end of the cylinder alternately full of steam direct from the boiler, and practically at the full boiler pressure, and thus forcing the piston along in exactly the same way as that in which it would have to be forced were water the fluid used instead of steam. If we imagine the cylinder to have a capacity of 7 cubic feet, then, if it be filled entirely with steam from the boiler at 60 lb. absolute pressure, it will contain nearly one pound-weight of steam. The total heat

in this pound of steam (above 0° C.), as given in the steam-tables, is equivalent to 655 lb.-calories in excess of that possessed by a pound of water at 0° C. When the piston, A, has reached the end of its stroke, the steam contained in the cylinder is thus in itself a great storehouse of work, for each lb.-calory is equivalent to 1400 'foot-pounds' of mechanical energy, so that the total represents about 917,000 foot-pounds, of which we shall see later on only about $\frac{1}{10}$ has been utilised during the stroke, leaving $\frac{9}{10}$ untouched. Instead of making any attempt to utilise this huge balance, at the moment when the cylinder is full of steam the opening C is put into communication with the boiler, the opening D with the atmosphere, and the steam immediately rushes out of the cylinder, and dissipates its contained energy through the air. Although the steam, when allowed to go into the atmosphere, is immediately reduced to the pressure corresponding to the temperature of the air (which in ordinary cases would be only a fraction of a pound per square inch), still the full pressure of the atmosphere itself will always be acting on the back of the piston during its stroke, and therefore, to find the force with which the piston is being pushed along, we must subtract that pressure from the steam-pressure. On the one side of the piston will be the atmosphere with its uniform pressure of nearly 15 lb. per square inch, and on the other side the steam-pressure of 60 lb. The effective pressure thus will be 60 - 15, or 45 lb. per square inch only.

Let us now consider the somewhat more economical case of an engine in which the steam is first used as described above, but afterwards, instead of being allowed to pass into the atmosphere, is conducted through a pipe into a closed vessel, which is maintained at a low temperature, and there in great part condensed. This reduction of temperature has a double effect on the steam: (1) the cooling and liquefaction of a part of it; and (2) the reduction of the rest to the pressure corresponding to the reduced temperature. It is not possible to do one of these things without the other. What is commonly called 'vacuum' simply means pressure less than the atmospheric pressure; and, in the case of steam-engines, a vacuum generally implies a pressure of between 2 and 3 lb. per square inch—i.e. from a seventh to a fifth of the ordinary pressure of the air. The most common way of condensing steam is by bringing it into contact either with a jet of cold water or with surfaces kept continually cool by a current of water. In either case, directly the steam is brought into contact with the water or cooling surface, it transfers to these cold bodies the larger portion of its heat. During this process the greater part of the steam is liquefied, and the remainder retains only such a pressure as corresponds to its greatly reduced temperature.

The advantages possessed by a condensing over non-condensing engine will now be obvious. When the piston is being forced from C to D by steam entering through C, the force on the back of the piston resisting its motion in that direction, instead of being equal to the pressure of the atmosphere, is only the pressure of the steam in the condenser, or about 2 lb. per square inch. The net effective force is therefore 60 - 2 or 58 lb. instead of 60 - 15 or 45 lb.

We have supposed that our cylinder when full of steam contained just one pound-weight at 60 lb. pressure. Let us now find out how much useful work this pound of steam has done for us, and we will then show how the same weight may be made to do a great deal more, by utilising more of its great store of heat. Let us suppose that the area of the cross-section of the cylinder is 2 square feet, while

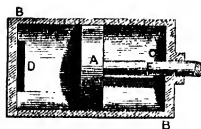

Fig. 2.

its length (the stroke of the piston) is $3\frac{1}{2}$ feet. It will thus have a capacity of 7 cubic feet, as before assumed. In the first case described we should have a pressure of 45 lb. per square inch exerted on an area of 288 square inches through a distance of $3\frac{1}{2}$ feet. This is equal to 45,360 foot-pounds of work. In the second case we have a pressure of 58 lb. per square inch on the same area and through the same distance. This is equal to 58,464 foot-pounds of work, or about $\frac{7}{8}$ of the total heat in the steam. (For simplicity's sake we have here assumed that the water in the boiler has to be raised from 0°C to 144.8°C , and evaporated at that temperature. If the water were supplied at 100°C , then the work done would be about $\frac{1}{8}$ instead of $\frac{7}{8}$ of the total heat.) We may now proceed to examine the way in which the same weight of steam, generated by the consumption of an identical weight of fuel, may be made to perform much more work by 'working expansively.'

One of the properties possessed by steam, in common with all other gases, is a tendency to expand indefinitely; its pressure varies nearly inversely as its volume. For simplicity's sake we shall here assume that steam is a perfect gas, and follows Boyle's law, the pressure varying *exactly* inversely as the volume. If then we have a cylinder of the same area as before, but of twice the length, but only intend to admit 1 lb. of steam into it at a time, it will be necessary, when the piston has travelled $\frac{33}{2}$ feet of its stroke, to shut the entrance valve, so as to prevent more steam entering; this is called 'cutting off' the steam. The piston, however, still continues its motion in the same direction as before, propelled by the internal separative energy among the particles of steam. But as it is pressed forward the space occupied by the steam is always increasing, and its pressure always decreasing in proportion, until at length, when the piston has reached the end of its stroke, the steam occupies exactly double its original volume—viz. 44 cubic feet, and is reduced in pressure to half its original pressure—viz. to 30 lb. per square inch. We have thus during the first half of the stroke a constant pressure on the piston of 60 lb. per square inch, and during the second half a pressure gradually decreasing from 60 to 30 lb. The *mean* pressure during this second half of the stroke will be found by calculation to be almost exactly 41·5 lb. Let us now, in the same way as before, see what work we have been able to get out of our pound of steam by expanding it in this way. In the first half of the stroke we have 58,464 foot-pounds of work exactly as before, and then we have in addition a mean pressure of 41·5 ÷ 2, or 39·5 lb. per square inch, exerted over 288 square inches for a distance of 33 feet. This equals 39,816 foot-pounds, making a total of 98,280 foot-pounds of work obtained from the steam which only gave us 58,464 before. The economy of working expansively, however, goes much further than this. If the cylinder had been four times its original length, and the steam had been cut off at the same point as before (which would then be quarter instead of half stroke), we should have obtained

from the 1 lb. of steam about 140,000 foot-pounds of work. If we had gone still further and expanded the pound of steam into eight times its

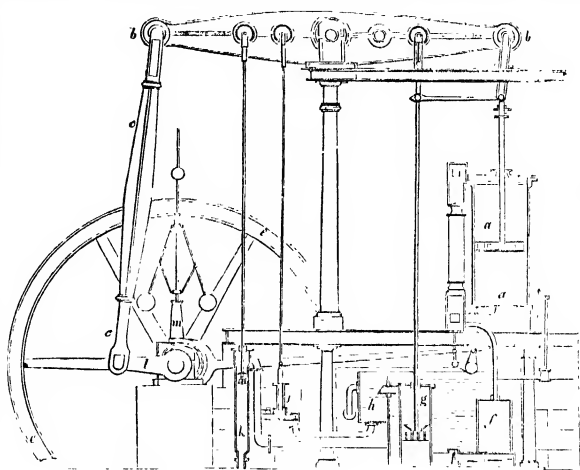

Fig. 3.

original volume, we should have obtained about 178,000 foot-pounds of work, which is more than three times as much as at first. (In actual working, owing to various causes such as imperfect action of the valves, radiation from the cylinder, bad vacuum, &c.—the work obtained from the steam is not more than $\frac{65}{100}$ of that given in this paragraph.) All modern engines are worked more or less on this principle of expansion, and the general tendency seems to be every year to adopt higher initial pressures and (within certain limits) larger ratios of expansion.

Fig. 3 represents Watt's 'double-acting' condensing engine. By 'double-acting engine' we mean an engine such as was sketched in fig. 2, in which the steam acts on both sides of the piston instead of only on one, as in Newcomen's engine. Watt's engine, though not of the form now generally used, contains all the parts now considered essential. The steam from the boiler passes direct to the valve-chest, *c*, which is simply a long box attached to the cylinder, *a*. In this chest are placed valves, which are so regulated as to open communication between the boiler, cylinder and condenser, in such a way that when the top of the cylinder is open to the boiler the bottom communicates with the condenser, and *vice versa*. When the steam has done its work it passes out through the bent pipe into the condenser, *f*, where it is met by a jet of water (not shown in the engraving), and condensed, as before explained; *g* is a pump called the air-pump, which continually draws away the contents of the condenser, and discharges them into a cistern, *h*, called the hot well. A small force-pump, *j*, draws part of the water from this cistern, and sends it back again to the boiler, there to be reconverted into steam, while the rest of the water is allowed to run to waste. A suction-pump, *k*, supplies water to the large tank round the condenser, and also for the condensing jet. Inside the cylinder are the piston and the rod (called the piston-rod) connecting it with the beam, *bb*. In Newcomen's engine the rod had only to pull the beam down, and not to push it up; it could, therefore, be connected to it by a chain,

shown in fig. 1. In the double-acting engine the piston-rod is required both to pull and to push the beam, so that the chain is no longer admissible. It is obvious that as the head of the rod must move in a straight line, while every point in the beam describes an arc of a circle, the two cannot be rigidly connected. Watt invented the arrangement of rods shown in fig. 3, by which the piston-rod head is guided in a line, very approximately straight, while the end of the beam is left free to pursue its own course. This is called a 'parallel motion.' The end of the beam farthest from the cylinder is connected by a rod, *cc*, called a connecting-rod, to the crank, *z*, which is firmly fixed on the shaft; and by this means the reciprocating motion of the beam is converted into the rotary motion of the 'crank-shaft,' *z*. The governor, *m*, and the flywheel, *ee*, will be explained further on.

The cylinder and its piston are both made of cast-iron or cast-steel. The former is very accurately bored in a special machine, and ought always to be covered outside with non-conducting material to prevent radiation of heat. It is frequently enclosed in another cylinder, and the annular space or 'jacket' between them filled with steam from the boiler, principally with the object of preventing liquefaction in the cylinder, which is fatal to economical working. The openings for the entrance and discharge of the steam (shown at C and D in fig. 2) are both called *ports*.

The *valves* or valves which regulate the admission of steam to the cylinder vary very much in construction and design. In small engines one valve, called a *slide-valve*, does the whole work in a way which we shall explain by the aid of fig. 4. This figure shows the valve in two positions, viz. those corresponding to the times when the piston is at the middle of its stroke, going in the two different directions; *c* and *d* are the ports, the ends of which are denoted by the same letters in fig. 2; *b* is the 'exhaust port,' or opening through which the steam passes to the condenser; and *a* is the slide-valve working inside the steam-chest (the latter not shown). The sketch to the left shows the position of the valve when the piston is moving upwards. The steam enters the cylinder through *dc*, as shown by the arrows, while the steam in the other end is free to rush out by *c* under the valve, and through *b* into the condenser. By the time the piston has reached the same position, going in the opposite direction, the valve is in the position shown in the right-hand sketch, and the motion of the steam is exactly reversed. The valve in fig. 4 opens one port at the same moment as it closes the other. This corresponds to entirely non-expansion working. In order to 'cut off' the steam before the end of the stroke the breadth of the ends of the valve must be increased. This is called giving 'lap' to the valve. When it is desired to 'cut off' the steam earlier than half-stroke, a separate valve called an *expansion valve* (of which there

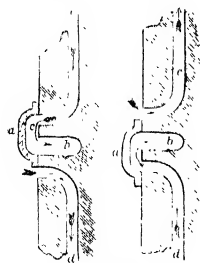

Fig. 4.

are innumerable varieties), is generally used. To relieve the pressure of the valve on its seat, in the case of large slide-valves, steam-tight rings are arranged so as to exclude the steam from the greater part of the back of the valve. A still better method

is to employ piston slide-valves, a common device in the H.P. cylinders of marine engines. In this form the valve face forms a complete cylinder, and the ports extend right round this cylinder. Another common form of valve in land engines is the lift or mushroom; this type reduces the clearance volume at the end of the cylinder, and it is easy to make such valves close almost instantaneously from the fully open position. The rod to which the piston is attached is called the *piston-rod*, and the rod which actually drives the crank the *connecting-rod*. In Watt's engine and similar machines these are connected to opposite ends of a *beam*, but in the common type of engine shown in fig. 6 (below) the two rods are directly attached. The *flywheel* is a large wheel fixed on the crank shaft, and having a very heavy rim. As it revolves this contains, *stored up* in itself, a great quantity of energy, and so equalises the motion of the shaft, and by *restoring* some of the energy enables the engine to pass the 'dead-points,' or points at which the connecting-rod and crank are in a line. The *jet condenser* is simply a cast iron box of any convenient shape. The water for condensing the steam is introduced into it in a jet in such a way that its particles mix with the steam at once on entering, and condense it almost instantaneously.

The *governor*, shown in fig. 5, is an ingenious application by Watt of mechanism long used in water-mills. Its object is to make the engine to

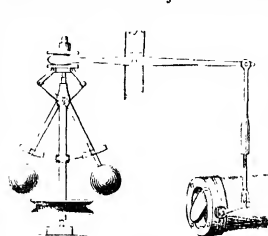

Fig. 5.

a great extent regulate its own speed, so that it shall neither be pulled up altogether by a sudden increase of load, nor 'race' when any part of its load is suddenly removed. It consists essentially of a spindle or upright rod, with a pulley by which it is caused to revolve fixed on it. Two levers are pivoted on a pin near the top of the spindle, and at the lower end of each is fixed a heavy cast-iron ball. When the engine is running at its proper speed the balls revolve with the spindle in the position shown; but if that speed be increased the centrifugal force causes them to fly outward, and consequently upward; and conversely, if it be decreased they fall downward towards the centre. At the upper end of the spindle is a system of levers, by which it will be seen that the raising of the balls tends to close, and their lowering to open, the *throttle-valve* at the right of the engraving. The valve in the figure is simply a disc of metal placed in the steam-pipe near the cylinder, but a great many other types of valve—more expensive but more efficient—are now used for the same purpose. The further this valve is opened the greater the amount of steam admitted to the cylinder, and *vice versa*, and so the tendency of the engine to alter its speed arising from causes extraneous to itself is just balanced by the alteration made in the amount of steam admitted through the throttle-valve. In order that economy as well as regularity of working may be attained, it is in many cases necessary that the governor should be so arranged as to control the 'cut-off' instead of throttling the steam as in the figure.

The 'Cornish' engine, so called from the fact that it was principally used in the Cornish mines,

resembles Watt's engine in general appearance. Like Newcomen's engine it is used exclusively for pumping and has no rotary motion, and it is virtually single-acting; but, unlike his, the steam-pressure and not that of the atmosphere actually does the work. Cornish engines are fairly economical of steam, but are very costly and extremely heavy and unwieldy.

Engines in which the piston-rod and connecting-rod are directly attached are called *direct-acting engines*, of which the horizontal engine shown in fig. 6 is the most common type. For all ordinary purposes direct-acting engines have superseded every other form. They possess the merit of having great simplicity and few working parts, and of all these parts being easily accessible to the engine-driver; and at the same time any required degree of economical working can be obtained in them as well as in any other form. They were at first only used as non-condensing (or so-called 'high-pressure') engines, but are now as frequently made with a condenser attached.

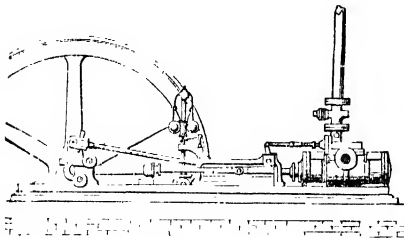

Fig. 6.

Direct-acting engines are now built to run at extremely high speeds, for driving dynamos direct. For this purpose they are sometimes made single-acting only, so that the steam-pressure tends always to keep the working surfaces pressed together, and there is none of the shock and noise

found in ordinary engines where the direction of pressure is reversed at each stroke. By improvements in design, and by the use of a system of forced oil lubrication, double-acting engines, such as the Belliss, are now run at very high speeds for dynamo-driving and similar purposes. Much labour and ingenuity have been expended in devising rotary engines, in which the reciprocating parts of the ordinary engine are abolished; but, except in the case of the Steam-turbine (q.v.), they have always proved a failure, being very uneconomical and expensive to maintain.

In *locomotive engines* it is necessary that the whole machinery should be compressed into the smallest possible bulk, and this necessity is the cause of their principal peculiarities. The engine itself is much the same as an ordinary horizontal engine, and has usually two cylinders placed side by side near the front of the locomotive. These cylinders are sometimes placed inside the main framing, which runs the whole length of the engine, and sometimes outside it. Fig. 7 is an outline section of a simple form of 'inside cylinder' goods-locomotive to illustrate the principle. (For more recent forms, see RAILWAYS.) At the back of the locomotive is the firebox, *a*, the bottom of which is formed by the grate, *b*. Fuel is introduced by the door, *c*. The firebox is enclosed in a casing, *d*, and the space between is filled with water. This space communicates freely with the barrel, *e*, *e'*, of the boiler, a long steel cylinder. From the back of the firebox numerous small tubes traverse the boiler (through the water) to the smoke-box, *f*, and conduct the products of combustion to the chimney, *g*. The steam-pipe, *h*, is led away from near the top of the dome, *h'*, and fitted with a regulator valve, *l*. At *m* are a pair of spring safety-valves. Both cylinders discharge their steam through the vertical blast-pipe, *p*, and by this means a sufficient draught is caused, notwithstanding the small height of the chimney. The cylinders, *r*, are placed in the bottom of the smoke-box, and partly enclosed in it.

Stephenson Link motion or some similar device such as the Joy valve gear is essential in all locomotives to secure rapid reversal of the direction of rotation of the crankshaft, and thus enable the

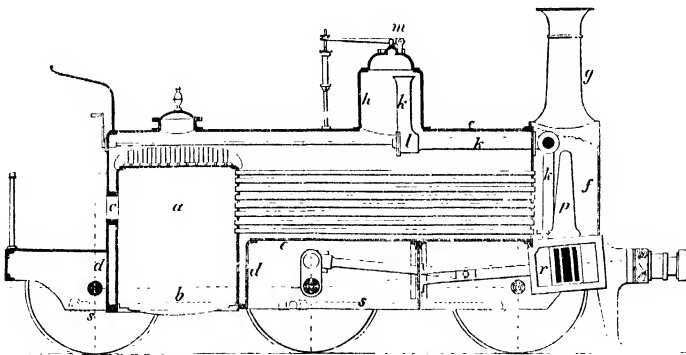

Fig. 7. Section of a Simple 'Inside-cylinder' Goods Locomotive.

locomotive to move with equal facility forward or backward.

Locomotive engines are now often made compound, and superheaters are frequently fitted between the boiler and the high-pressure cylinders in order to raise the temperature of the steam con-

siderably above the temperature of saturated steam corresponding to the boiler pressure, this superheating reducing initial condensation of the steam upon its entrance into the cylinders, and thus promoting economy in both steam and fuel, the saving in coal being from 20 to 25 per cent.

Two of the greatest improvements in the modern engine—the *surface-condenser* and the *compound engine*—were first brought to perfection chiefly in connection with marine engines. In the surface-condenser the steam is condensed by contact with the exterior surface of a great number of small tubes, through the interior of which a current of cold water is kept constantly flowing by the action of a pump termed the circulating pump. By this means the condensing water and the condensed steam are kept separate, the former being returned to the sea in marine engines, or into cooling-ponds or cooling-towers in the case of land engines (in pumping-engines some of the cold water pumped may be passed through the condenser tubes), and the latter only is sent into the hot well. In the case of marine engines the boilers are therefore fed only with distilled water, and the old wasteful process of 'blowing off' to get rid of the unvaporisable matter, which would otherwise be deposited in the boiler, is rendered unnecessary. Oil-filters are now usually fitted in order to remove the oil carried forward with the condensed steam to the hot well, and thus secure a pure water feed for the boiler.

In 'compound' engines the steam passes through two or three or four stages in the process of expansion. Each stage of the expansion is carried out in its own cylinder or cylinders, and these cylinders are of unequal size, the smallest being the one into which the steam first enters from the boiler, and the largest the one from which the steam passes to the condenser. The steam is admitted from the boiler into the smallest cylinder—called the high-pressure cylinder—in the usual way, and is cut off generally at from $\frac{1}{4}$ to $\frac{1}{2}$ of the stroke; and after doing its work there, it is conducted to the next cylinder, which in the case of a double expansion engine is called the low-pressure cylinder, where its reduced pressure, by acting on an increased piston area, does as much work as in the high-pressure cylinder, and thence it goes to the condenser. In engines of large power, triple expansion or quadruple expansion may be adopted; that is, the steam has to pass through one or more intermediate pressure cylinders, after leaving the high-pressure cylinder, before it gets to the low-pressure cylinder, these cylinders being intermediate in size between the high-pressure and the low-pressure, and the cylinders are so proportioned that the amount of work done in each of them is about equal. This system has several notable advantages, among which are that the driving pressures are more uniform than in the simple engine; that leakage past the piston becomes of less importance; that for any given *large* measure of expansion (an absolute necessity when high boiler pressures of 180 to 250 lb. per square inch are employed) the mechanism of the engine is much more simple than for the same degree of expansion carried out in one cylinder; and that the losses due to initial condensation of the steam in its entry into the cylinder after the valve opens (now known to be one of the most serious of all causes of waste) are much reduced. This reduction in the amount of initial condensation is due to the fact that by dividing the whole range of expansion of the steam over two or more cylinders, the range of expansion in each cylinder is lessened, and consequently the range of temperature in each cylinder is reduced.

Modern marine engines and mill engines are now always worked on the compound system. For the marine engine the inverted vertical type is now almost universal, the cylinders being placed right above the shaft. A common form is one having three cranks, especially where the engine is of the triple-expansion type; though for ships of high

speed it is usual, while still retaining the triple-expansion type, to have four cranks and four cylinders, there being two low-pressure cylinders of the same size; this arrangement secures a better balancing of the engine. Ordinary flat slide-valves are used for the low-pressure cylinders, and sliding piston-valves for all the other cylinders. For reversing the direction of rotation, and thus propelling the ship astern, the Stephenson link motion or some similar device is employed. A piston speed of 1000 feet a minute is not uncommon in some large marine engines, and even higher speeds under certain conditions; in this case some system of forced lubrication must be employed for crank-pins, main bearings, eccentrics, &c.

For mill engines, working compound, the tandem system, in which one cylinder is immediately behind the other, is often employed; or else the two cylinders may be on independent bed-plates, with the flywheel between them. When triple expansion is used, if there are three cylinders, two may be placed tandem on one bed-plate, and the third cylinder on a separate bed-plate. Trip valves are now usually fitted to the high-pressure cylinder; this system reduces the clearance volume, and enables the period at which the cut-off of the steam takes place to be changed without altering the period at which the steam is released from the cylinder, since the steam admission valves are quite distinct from the exhaust valves. In the Corliss system the exhaust valves are opened and closed by a link which is reciprocated by an eccentric; the steam admission valves are opened in precisely similar fashion, but are closed suddenly by springs when released or tripped by means of the governor. The governor controls absolutely the period in the piston stroke at which this closing of the valve shall occur, but the valve opens in the same way and at the same instant in each stroke no matter at what period the shutting of the valve may occur.

Many pumping-engines are non-rotative, as, for example, the Worthington steam-pump; in most cases these pumps are not very economical, since the inertia of the reciprocating masses is sufficient, owing to low speed, to secure uniform pump effort if steam is cut off at all early in the stroke. In the large-sized Worthington pumps, however, this difficulty is overcome by the use of 'compensators.' During the early part of the piston-stroke, when there is full steam pressure upon the pistons, part of the work is absorbed in driving in the pistons of the two compensating cylinders against a considerable hydraulic resistance of 200 to 300 lb. per square inch (these compensating cylinders are supported on hollow trunnions on which they can oscillate); this continues until the main pistons are at about mid-stroke and steam has been cut off; then during the rest of the piston-stroke, while the steam pressure is falling owing to expansion, the oscillation of the two compensators brings them into such a position that the pressure behind these pistons now tends to drive their pistons outwards, and so increases the force delivered to the pump-rams and the work available for pumping. In fact, apart from small friction and other losses, the whole of the work absorbed by the compensators in the first half of the stroke is given out again during the second half of the stroke.

Efficiency of the Steam Engine. Thermodynamic principles show that in the working of any heat engine it is essential that the working substance must in the course of a complete cycle pass from a higher temperature, at which it takes in heat, to a lower temperature, at which it rejects heat, the amount of work done in the cycle being measured by the difference between heat received and heat rejected. In the ideal cycle, in which every process

of the cycle is reversible and in which heat is only received at the higher temperature T_1 and only rejected at the lower temperature T_0 , the thermal efficiency would be given by the expression $\frac{T_1 - T_0}{T_1}$, the temperatures being measured on the

absolute scale. It used to be the practice to compare the actual thermal efficiency of any steam-engine as found by a test with this ideal 'Carnot' efficiency. An engine on the ideal Carnot cycle with steam as the working agent presupposes that we should combine the separate functions of boiler, engine, and condenser in a single vessel; but provided the working agent undergoes the same cycle of operations when these three vessels are, as they are in the actual steam-engine, separate organs, the thermal efficiency would be unaffected. It is necessary, therefore, to consider whether in this latter case we can practically carry out the same cycle of operations as in the Carnot cycle. The cycle of the actual engine, working between the same temperature limits as that of the Carnot engine, as a matter of fact does not do so; in its cycle it differs from the Carnot cycle in the omission of the adiabatic compression during the return stroke. The engine in the so-called Rankine cycle receives dry saturated or superheated steam at the temperature of the upper limit, T_1 , for a portion of the outstroke, this supply is then cut off, and the remainder of the outstroke is completed by adiabatic expansion, until the temperature and pressure of the steam has fallen to that which corresponds to the lower temperature limit, T_0 , the cylinder being then filled with wet steam; during the instroke the whole contents of the cylinder are discharged at constant temperature and pressure into the condenser. The feed pump then delivers this condensed steam into the boiler, where it is heated gradually from T_0 to T_1 , thus completing the cycle. Fig. 8 shows the pressure volume diagram for such a cycle. Since part of the heat supplied in the cycle, that required to warm the substance from T_0 to T_1 is supplied at lower temperatures than the upper limit T_1 , this cycle must of necessity be less efficient thermally than the Carnot cycle, but it is a much better standard of

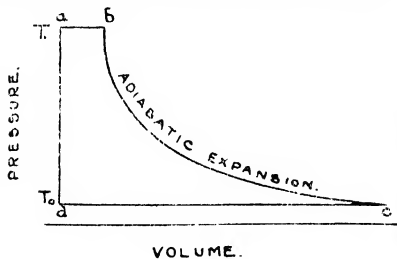

Fig. 8.

reference, since it is the actual cycle of the modern steam-engine with the sole difference that for practical reasons it is not possible to carry the expansion to such an extent as to reduce the temperature and pressure to that corresponding to T_0 . The Rankine cycle is therefore now adopted as the standard of comparison. The thermal efficiency of such a cycle, when the ideal engine uses dry saturated steam, can be found from the following expression:

$$\text{Efficiency} = \frac{\text{Work done}}{\text{Heat received}} = \frac{(T_1 - T_0) \left(1 + \frac{I_1}{T_1}\right) - T_0 \log \frac{T_1}{T_0}}{T_1 - T_0 + I_1}$$

The suffix i indicates initial, and f final, conditions; and L_1 and L_0 are the latent heats of the steam at the upper and lower temperatures T_1 and T_0 .

Thermodynamic problems in the steam-engine are much more easily considered if we utilise the idea of entropy, and draw instead of pressure volume diagrams another diagram the co-ordinates of which are temperature and entropy. Entropy (usually de-

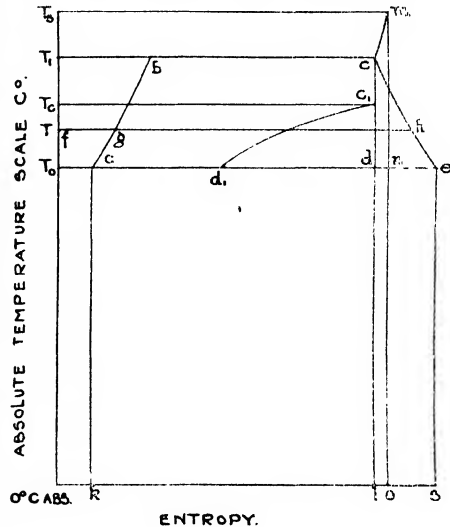

Fig. 9.

noted by the symbol ϕ) is defined by the fact that when a substance receives or rejects dQ units of heat at a temperature T , its entropy is increased or decreased by an amount $= \frac{dQ}{T}$. Since any small

change in the value of entropy such as $d\phi = \frac{dQ}{T}$, it follows that $T \times d\phi = dQ$; therefore any area in a temperature entropy diagram, or, as it is usually called, $\theta\phi$ diagram, represents to a known scale a quantity of heat; it follows, therefore, that such diagrams will simultaneously allow us to calculate the work done in a cycle and the total heat received and rejected.

In any cycle, such as the Carnot or the Rankine, the entropy at the end of the cycle is exactly the same as it was at the start, since the working agent is at the end of the cycle in the same condition in regard to temperature, volume, and pressure as it was at the beginning of the cycle. When a pound of water is heated from T_0 to T_1 and then turned into steam at this upper temperature T_1 , it gains entropy $= \log \frac{T_1}{T_0} + \frac{L_1}{T_1}$ (assuming that the specific heat of water is constant and equals unity). Fig. 9 shows the $\theta\phi$ diagram for the Rankine cycle. The curve ab represents the term $\log \frac{T_1}{T_0}$, and the curve bc the term $\frac{L_1}{T_1}$; that is to say at any temperature, say T ,

the length fg = to a selected scale $\log \frac{T}{T_0}$, and the length gh = to the same scale $\frac{L}{T}$. The figure

$abcd$ represents the Rankine cycle, ab the warming of the feed in the boiler from T_0 to T_1 , bc the evaporation of the water at the temperature T_1 , cd the adiabatic expansion to T_0 , and da the expansion of the wet steam into the condenser at T_0 . Since in any adiabatic process no heat is received or rejected, an adiabatic process must be represented on a $\theta\phi$ diagram by vertical lines. The area $abcd$ represents the work done in the cycle, the area under the lines ab, bc , that is the area $k'abrl$ the total heat received, and the area $adlk$ the heat rejected; hence it is possible to obtain at once from a $\theta\phi$ diagram the thermal efficiency for any chosen temperature range. The diagram further enables the dryness fraction at the end of the adiabatic expansion to be determined at once—it is given by the ratio $\frac{ad}{ae}$.

If the steam is released before the adiabatic expansion has reduced the temperature to T_0 , say at the point c , that is at the temperature say T_2 , and if the steam is then cooled to T_0 by the action of the condenser, the process is represented by the constant volume curve cd_1 , and the work done in the cycle is now only abc_1d_1a , while the heat spent remains the same, hence the efficiency is reduced.

The $\theta\phi$ diagram can be extended to the case of superheating beyond T_1 to a temperature T_2 at a constant pressure by drawing through c a curve cm , remembering that the gain of entropy in this process is nearly $=k \log_e \frac{T_2}{T_1}$, where k is the mean specific heat of superheated steam for this range of temperature; the extra work now available is represented by the area $cmnd$, and the additional heat spent by the area $cmol$. The real gain in efficiency by superheating is greater than would appear to be the case by inspection of the diagram, owing to the fact that superheating much reduces the initial condensation of the hot steam when introduced into a steam cylinder the walls of which have been cooled by the immediately preceding exhaust operation.

The actual efficiency of steam engines falls much below the possible efficiency as calculated for the same range of temperature in the ideal Rankine cycle, rarely exceeding 60 per cent. even under the best conditions; the loss is mainly due to incomplete expansion and initial steam condensation, though Callendar and Nicolson, as a result of their researches, express the view that leaky slide-valves, allowing steam to pass direct from the valve-chest to the condenser, account also for a certain not unimportant part of the loss of efficiency. The use of Corliss or drop-type valves much lessens initial condensation, the exhaust steam escaping by an entirely different valve and passage to that by which fresh boiler steam enters the cylinder.

It is usual to express the results of tests by giving the number of pounds of steam required per indicated horse-power hour; with saturated steam, figures as low as 11·2 lb. have been obtained, but for large well-designed engines the figure is more usually 13 or 14, and for ordinary compound engines 15 lb. is by no means a bad figure. When superheated steam is used—now a common practice—more economical results can be obtained, and figures as low as 9 to 10 lb. have been recorded in trustworthy trials, that is to say, a coal consumption of about 1·3 lb. per i.h.p. hour.

The steam-engine indicator, one of Watt's inventions, but greatly improved in details since his day, enables pressure-volume diagrams to be automatically drawn, giving not only a ready means of calculating very accurately the horse-power, but also of studying the action of the valves and of

determining the conditions of the steam at any point in the stroke after cut-off.

The mechanical efficiency of a steam-engine can be determined by absorbing the whole output of work by some form of brake—frictional or hydraulic—and the mechanical efficiency is the ratio of the work thus absorbed to the work done in the cylinder as determined by the indicator.

To determine the actual thermal efficiency of a steam-engine, its mean indicated horse-power must be determined for a selected period of time, the weight of steam used in the same period must be determined by measuring the weight of feed-water to the boiler, or the weight of condensed steam delivered by the air-pump, and the various pressures and temperatures of the water, steam, &c., must be accurately observed. From the data so obtained the efficiency can be calculated; tests should be made at full load, and at, say, $\frac{3}{4}$ load and $\frac{1}{2}$ load. The results, when plotted as graphs, showing total steam consumption per hour and steam per h.p. hour as compared with the h.p., will enable estimates to be made of the probable performance of the engine under any load. Where it is possible, brake tests should be carried out at the same time.

For other points, see articles STEAM, STEAM-TURBINE, ENERGY, THERMODYNAMICS, FUEL, SAFETY-VALVE, HORSE-POWER, INDICATOR-DIAGRAM, INJECTOR, AIR-ENGINE, INTERNAL-COMBUSTION ENGINES, RAILWAYS, SHIPBUILDING, &c. See also for theory, *Cottrell's Steam Engine as a Heat Engine*; Rankine's *Steam Engine*; *Scaton's Marine Engine*; Galloway's *The Steam Engine and its Inventors* (1881); Thurston's *History of the Steam Engine* (N.Y. 1878); Hughes's *Modern Locomotive* (1894); Fyving's *Steam Engine and other Heat Engines* (1926); Perry's *Steam Engine* (1899); Dally's *Steam Power* (1915).

Steam-hammer, a contrivance originally invented by Nasmyth in 1839, and since greatly improved in design and increased in power, consists essentially of a heavy framing carrying on the top an inverted steam-cylinder; the piston of this cylinder is attached by its rod to the hammerhead, or tup, and on the ground between the framing is a fixed anvil. It is usually double-acting, and can be worked in four ways: (a) as a single-acting hammer, no steam being admitted above the piston, and the blow may be a dead one or a cushioned and elastic one—to secure this latter effect steam is readmitted under the piston before the blow is finished; (b) as a double-acting hammer—in this case the intensity of the blow is increased by admitting steam above the piston, and again the blow may be a dead one or a cushioned and elastic one. Of recent years powerful hydraulic presses have been substituted to a great extent for large steam-hammers in heavy forging work.

Steam-plough. See PLOUGH.

Steam-turbine, a true rotary or non-reciprocating type of steam-engine. The working fluid, the steam, is either directed in the form of a jet or series of jets from one or several nozzles or guide-blades on to a series of vanes or buckets on the rim of the wheel, which is thus made to rotate; or the steam under pressure passes into the moving element of the wheel, and escaping by nozzles approximately tangentially, drives the wheel round by the reaction. The essential feature, in fact, is that the heat energy of the steam is first utilised to give motion to the steam, and thus give it kinetic energy, and then to do work upon the blades of the turbine.

Steam-turbines may be classed as (1) impulse or (2) reaction. The characteristic feature of the latter class is that the steam changes in pressure as it passes through the moving element of the wheel. Hero's molipile is an example of a pure reaction turbine, just as the De Laval turbine works purely by impulse. They may also be classed as (α) 'radial flow,' in which the steam either flows from the centre of the wheel outward to the circumference, or it may flow inward from the circumference to the centre; (b) 'parallel or axial flow,' the direction of flow being parallel to the axis of the wheel; (c) 'mixed flow,' in which there is both radial and axial flow. All three classes may be designed to work either as impulse or as reaction machines.

In order to understand the principle of the steam-turbine, it is necessary to consider the formation of the jet which is produced when steam is discharged under pressure. If we assume that the process is an adiabatic one, and if we neglect all frictional losses, the gain of kinetic energy is exactly equal to the loss of total heat, or, as it is commonly called, the 'heat drop'; if we further assume that the initial velocity of the steam is negligibly small, $\frac{V^2}{2g} = I_1 - I_0$, where V is the velocity acquired in feet per second, and I_1 and I_0 represent the total heat possessed by the steam in its initial and final conditions, hence it follows that $V = \sqrt{2g \times 1400(I_1 - I_0)}$, where I_1 and I_0 are measured in pound-calories, or $V = 300.2\sqrt{I_1 - I_0}$.

The volume occupied by the steam and its velocity both increase in value as the pressure of the steam falls during the process of expansion; at first the gain in velocity is relatively the greater, but in the later stages of the expansion the volume increases faster relatively than the velocity. This fact determines the cross-sectional shape of the nozzle through which the discharge takes place; the cross-section should contract from the entry to a narrow throat, and then should gradually enlarge to a size dependent on the final pressure of the steam.

In fig. 1 is shown somewhat diagrammatically the nozzle of a De Laval turbine set in the steam-chest D, and the moving buckets F. This nozzle

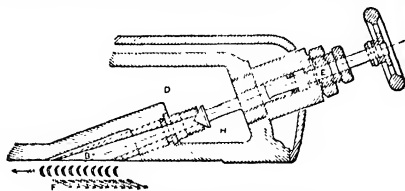

Fig. 1.—Nozzle for De Laval Turbine.

is of the divergent type; the throat or smallest cross-section is preceded by a rounded entrance so as to permit the steam lines properly to converge; then from the throat onwards the cross-section of the nozzle gradually enlarges, and is continued by a cylindrical shell cut off at B by a plane inclined at a small angle to the axis of the nozzle. In the figure the nozzle is shown fitted with a shut-off valve H, worked by the spindle E. A nozzle is properly designed when it provides for the discharge of a pre-determined amount of steam per unit of time, and when it allows such an expansion of the steam passing through it as to secure that the pressure of the steam leaving the discharge end of the nozzle shall be the same as that of the steam in the space into which discharge takes place.

It can be proved that the amount of steam discharged per unit of time by a nozzle depends only upon the initial steam-pressure and the cross-sectional area of the throat of the nozzle, and is quite independent of the final pressure, provided that the latter is not greater than about 0.545 of the initial pressure. The divergent portion of the nozzle enables the portion of the available heat-drop still unutilised to be employed in giving additional velocity to the steam. In a nozzle the expansion of the steam is too sudden for thermal equilibrium to be maintained; in the early stages of the expansion the steam is in a supersaturated state, and this condition is maintained beyond the throat, hence in this portion of the expansion the equation expressing the relation between the volume and pressure is $PV^{1.2} = \text{constant}$, and the steam-pressure in the nozzle-throat will be equal to 0.545 of the initial pressure. Owing to losses due to friction and other causes, the efficiency of nozzles is usually only about 0.9 to 0.95.

The De Laval turbine, the first patents in connection with which were taken out in 1882, carries out the whole expansion of the steam at a single step; or, in other words, the entire possible heat-drop is utilised at a single operation. The high-pressure steam enters one or more of the diverging nozzles shown in fig. 1, and issues from them in jet form and at an enormously high velocity, and impinges against the blades of the turbine-wheel, escaping at atmospheric or condenser pressure after giving up the greater portion of its kinetic energy to the wheel. In fig. 2 the thick curved line represents

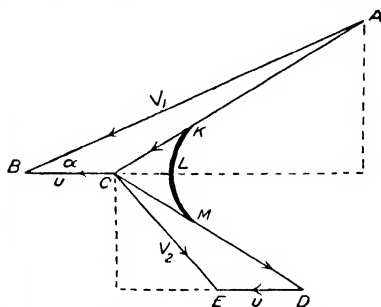

Fig. 2.—Velocity Diagram of Bucket of Turbine.

one of the buckets of the wheel, AB represents in direction and magnitude the velocity V_1 of the steam-jet as it leaves the nozzle, CB represents in direction and magnitude the velocity of the bucket, and hence AC represents in direction and magnitude the velocity of the steam 'relatively' to the moving bucket. The bucket deflects the steam-jet, and as the jet leaves the bucket its velocity 'relatively' to the bucket is denoted both in magnitude and direction by the line CD. Combining this with the actual velocity of the bucket itself, which is represented by the line ED=BC, we find that the line CE represents in direction and magnitude the absolute velocity V_2 of the jet after it has done its work upon the bucket. The steam has therefore lost, for each pound weight passing through the nozzle, energy in passing through the wheel

proportional to the difference between $\frac{V_1^2}{2g}$ and $\frac{V_2^2}{2g}$.

The larger part of this has been transmitted to the shaft as useful work, but a certain proportion has been lost in friction of the steam on the bucket surface. The working of a De Laval turbine is

in fact almost analogous to the working of the well-known Pelton water-wheel. The wheel-shaft must of necessity revolve at an extremely high speed (in a 5 h.p. turbine the revolutions are 30,000 per minute, and in a 600 h.p. machine 9500), and special flexible supports carry this shaft; the speed is then geared down by connecting the power shaft to the wheel-shaft by double helical tooth-gearing. In small sizes this turbine is relatively economical, but for generating large power compounded turbines are more economical. When worked with condensers the steam consumption of De Laval turbines per h.p. varies from 15 to 20 lb. per hour.

The De Laval is the only turbine of this type; other turbines are what is called compound, that is, there are a number of stages in the process of expansion, the total heat-drop being correspondingly divided into a number of stages, in each of which a new impulse is given to the steam after it has already given up a certain amount of kinetic energy to the turbine-blades it has just been in contact with. The number of such stages may be few, as, for example, in the Curtis type, or may be very many, as in the Parsons type. This division of the whole available heat-drop into a series of stages greatly reduces the necessary speed of rotation of the turbine-wheel to secure the best result, and the frictional losses due to the steam-jet rubbing against the blades are reduced; moreover, a steam-jet moving at excessive velocities, especially if it contains particles of water in suspension, exerts a cutting action on the wheel-blades.

The Curtis turbine is a pure impulse turbine; it uses what is termed a velocity-compounded wheel. There are two or more rings of jets, each taking up its own share of the energy of the steam. The action is as follows: A jet of steam, having acquired velocity in a fixed nozzle, impinges on a moving ring of blades, and gives up a certain portion of its kinetic energy to these blades. Leaving these moving blades with its velocity somewhat reduced, it impinges on a ring of suitably shaped fixed blades; these turn it in the proper direction to strike the second ring of moving blades, to which it gives up another portion of its kinetic energy; it may then go on to another ring of fixed blades, and from these to another ring of moving blades; and so on. The fixed blades merely change the direction of the stream; no loss of pressure takes place while it is passing over either fixed or moving blades. The Curtis turbine is generally worked on what is termed the compounded system; or, in other words, the available heat-drop is divided into two or more stages. Each stage consists of the nozzles and the wheel carrying the blades. In expanding through the first set of nozzles the steam pressure falls to that of the chamber in which are the first sets of moving and fixed blades. Having done its work in this chamber, the steam passes once more through a set of nozzles, the second set, into the second chamber, falling in pressure and again acquiring velocity. In this second chamber are a second series of moving and fixed blades, and the steam does further work in this chamber. From this chamber the steam may pass through a third set of nozzles, again falling in pressure and gaining velocity, into a third chamber with its series of moving and fixed blades, and so on until the complete available heat-drop has been utilised. This arrangement secures a moderate velocity at each stage, and a moderate speed of the blades. The Curtis turbine may have its shaft vertical, the wheels lying in horizontal planes, with the electric generator placed on top of the turbine, but when used for marine work the shaft is horizontal and the wheels lie in vertical planes. Many compound

impulse turbines utilise as the first stage of the expansion process a two-row Curtis wheel with partial admission, the nozzles being arranged in sets, one set supplying sufficient steam for, say, half load, two sets sufficing for the full load, and another set being only brought into use in case an overload is required. Since in modern turbine work superheating is practically always used, the Curtis wheel has certain practical advantages, as in the initial stage the steam temperature is reduced in the nozzles to a considerable extent before it comes into contact with the moving blades and the main portion of the turbine case, a matter of much importance if the casing is cast iron.

Another successful impulse steam-turbine is that designed by Rateau, which is like a series of De Laval wheels all strung on to the one shaft, each driven by the exhaust steam of the one before it. Each impulse-wheel is enclosed in its own chamber and it is separated from the next by a diaphragm which contains the fixed vanes or nozzles which deliver the steam with increased velocity to the next wheel. To begin with, the fixed nozzles are only fitted to a portion of the circumference of the diaphragm. But the arc of the circumference over which the nozzles extend increases with each successive diaphragm. A turbine of this type was installed in the electric tramways generating station of the London County Council. The contract conditions specified that when running at 750 revolutions a minute, and supplied with steam at 180 lb. gauge pressure, and with a vacuum of 27 inches, each unit should be able to develop in normal working 5000 kilowatts with a power factor of 0.85. The steam consumption under these conditions with the steam superheated to 500° F. was not to exceed 15 lb. per kilowatt hour, the vacuum being 28½ inches. It was also specified that each unit should be capable of taking a 25 per cent. overload at the same power factor without the use of a bypass valve. The Zoelly turbine differs from the Rateau only in certain mechanical details.

The Parsons Turbine. Mr (now Sir Charles) Parsons took out his first patent in 1884, and since that date he has so perfected and improved his turbines that turbines have now displaced the reciprocating engine for the generation of power on a large scale, both for marine and land work. His first successful condensing turbine was erected in 1891 for the Cambridge Electric Supply Company. It was a radial-flow machine, and under test it proved to be practically as economical in steam consumption as the best reciprocating steam engine of equal power at that date. The Parsons turbine works in part by impulse and in part by reaction. The rings of moving blades receive the impact of the jets directed on to them by the fixed rings of blades. But in addition there is a drop of pressure in the moving-blade channels as well as in the fixed-blade channels, and to this extent, therefore, the turbine works by reaction. The steam is arranged to acquire velocity and to lose pressure to the same extent in a ring of moving as it does in a ring of fixed blades; each pair of rings of blades forms a 'stage,' the number of stages depending on the intended peripheral speed of the drum.

A section through a Parsons turbine is shown in fig. 3. This turbine was designed to develop 1500 kilowatts at 1500 revolutions per minute, when using steam at 175 lb. gauge, superheated 150° F. The rotor is made in four diameters; steam enters the casing at the annular port A, and passes away to the right-hand end through eight groups of blades before passing to the condenser. The end thrust on each of the four drums is balanced by a dummy piston of the mean diameter of the blading; these dummies are immediately to the left of the steam port A. Each drum is balanced separately by

means of equalising pipes shown on the figure, and this equalises the pressure on the dummy with that which acts on the drum. These pipes are all outside the casing, and they are curved so as to provide for expansion changes. For the purposes of overload, bypass steam is admitted to the port B.

The rotor is made of a steel forging machined inside and outside; the ends are bolted to heavy solid flanges on the two end shafts. The upper part of the casing is hinged to the lower at each end, so

that the turbine may be readily opened for inspection. For the reception of the moving and fixed blades, parallel grooves are turned in the rotor and bored in the casing. In these grooves the blades are inserted alternately with the distance or 'caulking' pieces made to the exact shape of the space between blades and groove walls, until the groove is filled with a complete ring of blades, and the distance pieces are then carefully caulked. A lacing strip let into notches cut in the blades is

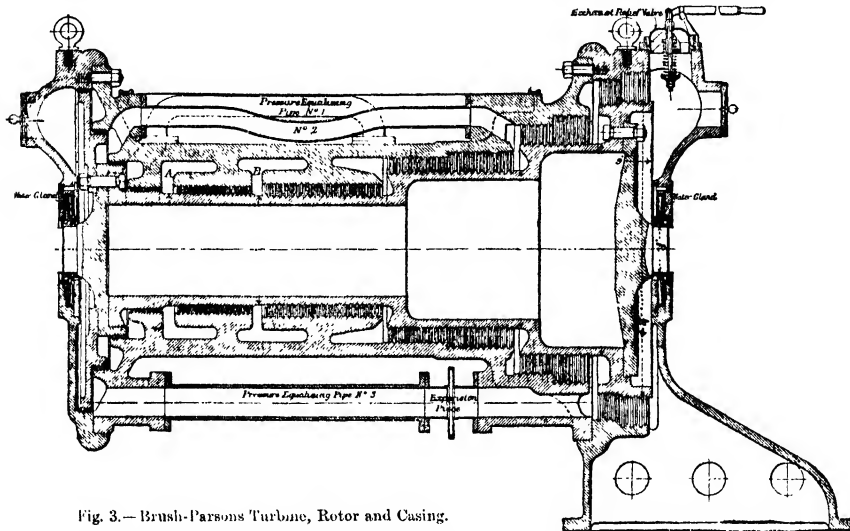

Fig. 3.—Brush-Parsons Turbine, Rotor and Casing.

then fixed in position, and finally cut at four or five places around the circumference to give flexibility and to allow for expansion. Each blade is reduced to a thin edge at its tip to diminish dangers of stripping. In the final stages leakage of steam past the blade tips is negligible, but with the short blades used in the earlier stages the leakage loss is serious unless special devices to reduce it are employed, and Parsons now shrouds the blade tips by means of a ring with a projecting sharp edge; this edge runs nearly in contact with a flat surface formed by one side of the bases of the next ring of blades, and there is a special device by means of which the clearance between the sharp edges and the flat surfaces can be adjusted to any desired amount. The roots of the rotor-blades and the grooves in the rotor into which they are fixed are corrugated to give more holding-power to the blades to resist the centrifugal forces. In the ideal form the steam passage should be continuously enlarged from row to row of the blades, so as to allow for the continuous increase in the volume of the steam as its pressure decreases. In practice it is more convenient to make the necessary changes in a comparatively few steps; in each step there are several rings of blades of the same size.

As an illustration of the wonderful development of the Parsons reaction turbine, the following particulars of a 50,000 kw. machine supplied in 1925 for a Chicago power-station are interesting. There are three cylinders, in the h.p. cylinder the boiler-steam at a pressure of 800 lb. expands through thirty-six stages to a pressure of 115 lb. absolute. The exhaust from the h.p. cylinder goes back to

the boiler-house to a reheater, where its temperature is raised to 700° F., then it passes through the i.p. cylinder and expands through twenty-three stages to an absolute pressure of 2 lb.; the exhaust from the i.p. cylinder then passes to the l.p. cylinder, where it expands in five stages down to a vacuum of 29½ inches; there are thus sixty-four stages in all. The blade-lengths vary from 2½ inches on the first ring to 40 inches on the sixty-fourth ring. The speed of the h.p. and i.p. shafts is 1800 revolutions per minute, that of the l.p. shaft 720, and the maximum blade tip velocity is 760 feet per second. It is estimated that when running at full load the normal electrical output will be equivalent to about one-third of the total heat supplied to the steam.

Application of the Steam Turbine.—On land the turbine has found its chief use in central stations for generating electrical energy on a huge scale for distribution over large areas of country for power and lighting purposes; being much more economical in steam consumption it has now practically entirely displaced the reciprocating steam-engine for such purposes. In the case of large units the turbine can be direct coupled to the alternator, and at the present day units of 20,000 kw. are in common use in central stations, and, as in the case of Chicago already mentioned, units of 50,000 kw. or of even greater output are not infrequently installed. The speed of the turbine may be from 1500 to 3000 revolutions per minute, which allows the best results to be obtained as regards consumption of steam. When continuous current dynamos are driven, it is usual to employ gearing between the turbine and the dynamo shafts.

For marine work, since the date of the successful trials of the famous *Turbinia* in 1897, and her performance at the great naval review in the Solent, the steam-turbine has almost displaced the reciprocating steam-engine. The decision in 1901 to fit the two great Atlantic liners the *Lusitania* and the *Mauretania* with turbines capable of developing the 70,000 h.p. required to drive them because of their exceptional size and speed was the turning-point in the struggle between the two types of steam-engines, and by 1918 over 15,000,000 turbine-generated horse-power was employed for marine purposes. In the *Aquitania* the turbines developed 60,000 h.p. and drove direct four propeller shafts each at 155 revolutions per minute. The two wing shafts had h.p. and l.p. turbines respectively, and the two middle shafts had a pair of l.p. turbines taking the steam in parallel; the steam thus expanded through three cylinders. For going astern the wing shafts had each a separate h.p. element running reversed, working in series with corresponding reversed elements on the l.p. turbines. In 1910 Parsons experimented with geared turbines on the *Vespasian*, a pair of 5-inch pinions on the high and low pressure turbine shafts was geared by double helical teeth with a wheel of 99½-inch diameter on the propeller shaft. The experiments were completely successful, and since 1914 the use of geared turbines for marine work has been greatly extended; by 1925 over 16,000,000 h.p. developed by geared turbines was in use; in the H.M.S. *Hoof* 144,000 h.p. was supplied to the four propeller shafts through gearing. Both single and double reduction gearing are now employed in marine work, the latter being specially suitable for slow speed steamers.

A steam-turbine can extract work out of steam when the pressure has become so low and the specific volume so great that an ordinary reciprocating engine would be quite ineffective. With the turbine it is, therefore, a matter of the utmost importance to maintain as perfect a vacuum as possible in the condenser, and various devices have been invented to secure this object, most of them based on Parsons's vacuum arguometer. In most cases the air is extracted from the condenser separately by means of two steam jets acting in series and discharging the air against atmospheric pressure. The condensed steam is dealt with quite independently by means of a small centrifugal pump delivering the condensate into the feed-tank. When there is an abundant supply of condensing water at a low temperature it is possible to obtain a vacuum of 29 inches.

The thermal efficiency of the steam-turbine has been steadily improved by increasing the temperature range, both by using higher boiler pressures combined with superheating and by securing a better vacuum in the condenser. In 1907 a steam consumption of 13·19 lb. per kilowatt hour was thought to be an excellent result—it meant that about 64 per cent. of the available heat-drop was utilised; in 1918 a test of a 25,000 kw. Parsons turbine gave a steam consumption of 10·84 lb. per kilowatt hour—in this case about 77 per cent. of the heat-drop was utilised.

By bleeding the steam at several points in the course of the fall of the pressure of the steam as it passes through the turbine for the purpose of heating the feed water, in combination with high initial pressure steam, high superheat, reheating the steam between the h.p. and the l.p. cylinder and the high vacuum now possible, a thermal efficiency of 33 per cent. may be obtained in the near future.

In a water-turbine there is no change in the volume of the working fluid—the same volume of water passes away into the tailrace as enters the

wheel; but in the case of steam it undergoes an enormous increase in volume as its pressure falls in passing through the turbine. For this reason a radial-flow turbine has many advantages, and was the type adopted by Sir Charles Parsons in the early days of his work; but difficulties connected with leakage at the tips of the blades led him to revert to the parallel-flow type. Another difficulty in turbine design arises from the necessity of securing a good ratio between steam speed and blade speed. In the radial type this difficulty might be got over, and many attempts were made to design such turbines to work with reasonable economy, but leakage difficulties always proved too serious an obstacle. Mr Ljungström, of Sweden, has, however, successfully attacked the problem, and designed a reaction turbine of the radial-flow type with high economy. In a test of a 5000 kw. machine the steam consumption was only 10·36 lb. per kw. hour, an extraordinarily good result.

To determine the horse-power given out by a steam-turbine the indicator cannot of course be employed, and for large turbines, especially those used for marine purposes, some form of torsion meter is now always employed. The angle of twist of a known length of the shaft is measured by a torsion meter while the turbine is running; then by a simple calculation, based upon the known cross-sectional dimensions of the shaft and the known modulus of rigidity of the steel out of which the shaft is made, the torque, M , of the shaft for the observed twist is determined; the work done by the turbine in foot-pounds per minute is equal to the torque M multiplied by 2π times the number of revolutions of the shaft per minute. The angle of twist is measured by the torsion meter by determining the relative angular displacement of two collars which are clamped to the shaft at a distance apart which is accurately known; optical or electrical methods are usually employed to make this measurement, and since the twist measured is always a very small angle, great care must be exercised in making the observations if the results obtained are to be at all reliable.

See H. M. Martin, *The Design and Construction of the Steam Turbine* (1913); Sir J. Ewing, *The Steam Engine* (1926); Stodola, *The Steam Turbine* (1905); Sir Charles Parsons, *The Steam Turbine* (1911); W. J. Goudie, *Steam Turbines* (1922); and numerous articles in *Engineering and Engineer*, 1900–1926.

Stearin, one of the fats occurring in animals and plants, may like the other fats be regarded as an ether of the triatomic alcohol glycerine, all three hydroxyl molecules being replaced by radicals of the fatty acid, stearic acid. It is the chief constituent of the more solid fats, such as mutton suet, and is characterised by its high melting-point—from 53° to 66° C.—by its slight solubility in alcohol as compared with palmitin and olein, and by its crystallising from its alcoholic solution in the form of brilliant quadrangular plates. For Physiology of Fats, see FATS. See also CANDLES, OILS.

STEARIC ACID, one of the solid fatty acids occurring as a glyceride (stearin) in most fats, is as known to commerce really a mixture of stearic and palmitic acids. Pure stearic acid, which may be easily separated from this mixture (by help of magnesium acetate, &c.), is a colourless crystalline substance having neither taste nor odour, and melts at 69° C. It is insoluble in water, on which it floats, but dissolves in alcohol and ether, its solution reddening litmus powerfully. The only stearates that are soluble in water are the stearates of the alkalis, whose solutions are frothy and form a lather. Free stearic acid occurs in decomposing pus and the caseous deposits of tuberculous. In combination it is found in faeces, in adipocere, in blood, and in serous fluids.

Stearns, WILLIAM AUGUSTUS (1805-76), born at Bedford, Massachusetts, studied at Harvard and Andover, was ordained to the Congregational ministry in 1831, and in 1854 became president of Amherst College. He published various addresses and discourses.

Stentite, or SOAPSTONE, a compact or massive variety of Talc (q.v.), is a hydrous silicate of magnesia, found massive, or assuming the forms of the crystals of other minerals which it has replaced. It is generally white, reddish white, or yellow, soft and greasy to the touch, and easily cut, but broken with difficulty. It is used by glaziers for marking plates of glass, and by tailors for marking cloth. It is also used in the manufacture of porcelain, by shoemakers in trying on new boots, in the process of casting, and for dressing some kinds of paper. Brancion Chalk, French Chalk, and Venice Talc, as it is called, readily absorbs oil or grease, and is the basis of Rouge (q.v.). It is used for imitating engraved stones, being easily cut, hardened by heat, and then coloured by metallic solutions. It also forms a polishing material for serpentine, alabaster, and glass. In China it is sometimes carved into images, miniature pagodas, &c.

Steatopygia, an exceptional accumulation of fat on and about the human buttocks, behind and round to the front of the thigh; common in Bushmen (q.v.) and Hottentots, and occurring also in central African pygmies, and specially conspicuous in women. In some tribes it is considered ornamental. The representation of this human formation in the prehistoric caves of France has been held to support the theory that a steatopygous race, possibly cognate with the African one, once existed in Europe.

Steatornis. See GUACHARO.

Stebbing, THOMAS ROSCOE REDD (1835-1926), born in London, studied at King's College School and King's College, and at Oxford was a scholar of Lincoln and a fellow of Worcester, where he was a tutor. He devoted himself to natural history, prepared the *Challenger* Report on the Amphipoda, and specially concerned himself about the Crustacea. His works include *A History of the Crustacea* and *Essays on Darwinism*, as well as a translation of Longinus *On the Sublime*.

Stedman, CHARLES (1753-1812), born at Philadelphia, Pennsylvania, was educated at William and Mary College, and studied law. He served under Howe and Cornwallis on the royalist side, and wrote a standard history of the Revolutionary War from the British point of view, specially valuable for its military maps.

Stedman, EDMUND CLARENCE (1833-1908), poet and critic, was the son of a merchant at Hartford in Connecticut. He studied at Yale, and early took to journalism, was on the staff of the *New York Tribune*, and was war-correspondent of the *New York World* during the war, but ultimately became a stockbroker at New York. He contributed actively to the more important magazines, and published various collections of verse: *Alice of Monmouth*, *An Idyll of the Great War*; *The Blameless Prince*; *Hawthorne and Other Poems*; *Lyrics and Idylls*. His *Victorian Poets*, a handbook to the poetic literature of England for two generations, appeared in 1875, was at once accepted as a work of standard value, and passed through many editions. The *Library of American Literature*, edited by him in conjunction with Ellen M. Hutchinson, was completed in 1890 in 11 volumes. Some of his lyrics are very fresh and admirable, and most of his work shows careful and artistic finish. As a critic, he was less remarkable for profound insight or discrimination than for breadth and sympathy.

Steedman, CHARLES (1811-90), born at Charleston, S.C., became a naval officer, was attached to the naval observatory at Washington, and in the Civil War did distinguished service on the Federal side. Afterwards he commanded the Boston Navy Yard, and retired a rear-admiral.

Steel. See IRON AND STEEL.

Steel, FLORA ANNIE, *nee* WEBSTER, born at Harrow, 2d April 1847, married a Bengal civilian, and lived in India 1867-89, returning subsequently to England. She was for some time inspectress of government schools in the Punjab. In conjunction with Colonel (afterwards Sir Richard) Temple she published in 1884 *Wide Awake Stories* and a collection of Punjab folk-tales. After her return she produced a series of novels and short stories illustrating Indian and Anglo-Indian life. Among the best known of her works are *From the Five Rivers*, *Red Romans*, *On the Face of the Waters*, *The Hosts of the Lord*, *A Book of Mortals*, *India through the Ages* (a history), *A Prince of Dreams*, *The Gift of the Gods*, *Mistress of Men*, and *The Law of the Threshold*.

Steelbow (a word of doubtful origin), in Scots law, means goods, such as corn, cattle, straw, and implements of husbandry, delivered by the landlord to his tenant, by means of which the latter is enabled to stock and labour the farm, and in consideration of which he becomes bound to return articles equal in quantity and quality at the expiration of the lease.

Steele, SIR RICHARD, the father of the Queen Anne essay, was born in Dublin in March 1672 (n.s.), and was there baptised at St Bridget's Church. His father, Richard Steele of Mountain (Monks-town), was an attorney; his mother had been a widow named Elinor Symes. His father died when he was a child (*Tatler*, No. 181). Mrs Steele did not long survive her husband, and the boy fell to the charge of an uncle, Henry Gascoigne, secretary to the first Duke of Ormond. Through Ormond's influence, in November 1684 Steele was placed upon the foundation at the Charterhouse, where he had Addison, his junior by six weeks, for contemporary. In December 1689 he entered Christ Church College, Oxford, and in March 1690 he matriculated. He tried hard for a Christ Church studentship, but eventually (in 1691) gained a post-mastership at Merton. At the university he was popular and respected, but in 1694 he suddenly enlisted as a cadet in the second troop of Horse Guards, then commanded by the second Duke of Ormond, thereby surrendering, according to his own account, some rather vaguely described expectations as a Wexford landowner. Already at college a dabbler in verse, in 1695 he made his appearance as a printed poet by *The Procession*, a conventional effusion on the funeral of Queen Mary, which he dedicated to John, Lord Cutts, who forthwith made him his secretary, and finally gave him a standard in his own regiment of Coldstream Guards. In June 1700 he became involved in a duel with an Irishman named Kelly, whom he had the misfortune to wound severely. One outcome of this occurrence was the production of the devotional manual known as *The Christian Hero*, which was written at the Tower Guard, and published in April 1701. With the public it was popular, but, as might be anticipated, it was regarded by Steele's military comrades as incompatible with his calling as a 'gentleman of the army.' 'From being thought no undelightful companion,' he 'was soon reckoned a disagreeable fellow;' and the necessity to 'enliven his character' drove him to the odd expedient of writing a play. This, *The Funeral*; or, *Grief à la Mode*, was acted at Drury

Lane in December 1701. It was followed in 1703 by *The Lying Lover*, and in 1705 by *The Tender Husband*. About this time, it is supposed, being now a captain in Lord Lucas' Regiment of Foot, he engaged in certain researches for the 'philosopher's stone,' the details of which rest mainly upon the authority of that 'cornucopia of scandal,' the *New Atlantis* of Mrs De la Rivière Manley, although the fact of the researches is not denied. Their failure is practically synchronous with his marriage to a widow named Margaret Stetch (with estates in Barbadoes). The marriage took place in 1705, and the lady died two years later. In August 1706 Steele was appointed gentleman-waiter to Queen Anne's consort, Prince George of Denmark; and a few weeks after his wife's death, upon the recommendation of Arthur Mainwaring (who, like Steele, was a member of the Kit Cat Club), he was appointed by Harley, then a Secretary of State, to the post of Gazetteer, the annual salary of which was increased to £300. By this time, it is presumed, he had quitted the army; but he continued to be spoken of as 'Captain' Steele. The next notable occurrence in his life was his second marriage, in September 1707, to the beautiful Miss Mary Scurlock, the daughter of Jonathan Scurlock, deceased, of Llangunnor in Carmarthen, and the 'True' of her husband's correspondence. Shortly afterwards, by the death of Prince George, he lost his court appointment. Then, without much warning, appeared on the 12th April 1709, the first number of the famous tri-weekly paper known as the *Tatler*, the putative author of which was one 'Isaac Bickerstaff,' a pseudonym borrowed from Swift. In January 1710, during the course of the *Tatler*, Steele was made a commissioner of stamps, and for some obscure reason was deprived of his gazetteership. The *Tatler* came to an end on 2d January 1711, to be succeeded in March by the more famous *Spectator*, which ceased 6th December 1712. To the *Spectator*, in March 1713, followed the *Guardian*. In all these enterprises Steele enjoyed the aid, as a contributor, of his friend and schoolfellow Addison—an aid the incalculable value of which he acknowledged with loyal cordiality. 'I fared (he said) like a distressed prince, who calls in a powerful neighbour to his aid; I was undone by my auxiliary; when I had once called him in, I could not subsist without dependence on him' (Preface to *Tatler*, vol. iv.).

In beginning the *Guardian* Steele had made prudent profession of abstinence from political questions. But the moment was not favourable to restraint, even for less earnest men. From his youth he had been an ardent adherent of the Revolution, and now, as it was thought, the Hanoverian succession was in jeopardy. Before April 1713 he was involved in a bitter quarrel with Swift. Then the disquieting rumours that the demolition of the Durrkirk fortifications, which was provided for by the treaty of Utrecht, would not be insisted on drew from him an indignant pamphlet entitled *The Importance of Durrkirk consider'd*, to which Swift, on the other side, grimly retorted with *The Importance of the 'Guardian' consider'd*. Steele in the meantime had resigned his commissionership of stamps, and entered parliament as member for Stockbridge, concurrently dropping the *Guardian* for the professionally political *Englishman*. Shortly afterwards he published *The Crisis* (1714), a pamphlet on the Hanoverian succession, to which Swift replied with matchless irony by *The Publick Spirit of the Whigs*. When Steele actually entered upon his duties in the House he found he was a marked man. He was promptly impeached for seditious utterances in *The Crisis*, and, although he made a capable defence, was expelled. But with Anne's death, a few months subsequently, his party came

into power and his troubles ended. In his best pamphlet, *Mr Steele's Apology for Himself and his Writings* (1714), he has given his own account of this part of his career.

That career, as far as literature is concerned, practically closed at this point. He again became a member of parliament, being returned for Boroughbridge; and a little later, upon presentation of an address to King George I., was knighted. He continued to produce periodicals and pamphlets, none of which are of great importance, though one of them, *The Plebeian*, had the effect of involving him in a painful controversy with his friend Addison. He was made a patentee of Drury Lane Theatre, where in 1722 he produced *The Conscious Lovers*, his best comedy. He also established the *Censorium*, a sort of æsthetic music-hall; and he devised an impracticable 'fish-pool,' or well-boat for bringing salmon alive from Ireland. In December 1718 he lost his wife. He survived her for nearly eleven years, dying ultimately, 1st September 1729, at Carmarthen, where he was buried in St Peter's Church. Of his four children only two were living at his death. His daughter Mary soon followed her father; and the remaining and eldest child, Elizabeth, married a Welsh judge, afterwards the third Lord Trevor of Bromham.

Steele's character has suffered from various causes, among which may be reckoned the animosity aroused by his political writings, the careless candour of his own admissions of frailty, and the habitual comparison of his weaknesses with the colder and more equable goodness of Addison. He has been specially branded as intemperate, but there is no sufficient evidence why in this respect he should be singled out from his contemporaries. That he was incurably sanguine, and that he constantly mistook his expectations for his means, is manifest from his lifelong embarrassments. But these were the result of an improvident temperament and an uncertain income rather than of a vicious habit of mind; and he made a noble and successful attempt to pay his debts before he died. Upon the whole he was a warm-hearted and benevolent man, a devoted husband (some of his letters to his wife are among the most unfeigned in the language), a loving father, and a loyal friend.

As a literary man he may be more exactly estimated. Though he wrote verse, he has no claims as a poet. His plays are commendable efforts in the direction of the stage-purification advocated by Jeremy Collier; but their feeling for humorous character is more notable than their stage-craft, and they have never kept the boards. His political pamphlets were honest and straightforward, but not effectively polemical; and he had a terrible enemy in Swift, who as a former friend had learned his adversary's weakest side. His fame rests almost wholly upon his performances as an essayist. And here he was by no means the colourless colleague of Addison that is sometimes supposed. On the contrary, he was nearly always the fore-running and projecting spirit, and his ready sympathies and quick enthusiasm occasionally carried him to an altitude which Addison never attained. If he wanted Addison's restraint, his distinction, his exquisite art, he nevertheless rallied folly with admirable good-humour, rebuked vice with unvarying courage and dignity, and earned for himself the lasting gratitude of the 'beautiful sex,' as he called them, by the chivalry, the manliness, and the genuine respect with which, almost alone in his age, he spoke of women.

Steele has been written of by Macaulay and Thackeray, but most sympathetically by John Forster (3d ed. 1860). See the Memoir (1886) by Austin Dobson, the writer of the above article, and the detailed Life (1889) by G. A. Aitken.

Steell, SIR JOHN, R.S.A., sculptor, was born at Aberdeen in 1804, the son of a carver and gilder. He received his education as an artist at Edinburgh Academy, and afterwards at Rome. In 1832 he modelled 'Alexander and Bucephalus,' which, however, was not cast in bronze until 1883, being erected in Edinburgh the year after. The promise of this early work he subsequently fulfilled. Most of his chief works are in Edinburgh: the colossal figure of Queen Victoria crowning the front of the Royal Scottish Academy, which procured him the honorary appointment of Sculptor to Her Majesty in Scotland; the statue of Scott in the Scott Monument; the equestrian statue of the Duke of Wellington (1852); statues of Professor Wilson, Allan Ramsay (1865), and Dr Chalmers (1878). At the inauguration of the equestrian statue of Prince Albert in 1876 Steell was knighted. Other works, in bronze or marble, are statues of Admiral Samarez in Greenwich Hospital; of the Marquis of Dalhousie at Calcutta; of Sir Walter Scott (1872) at New York; and of Burns at New York (1873), Dundee, and London. He died 15th September 1891.

Steelyard. See BALANCE. And for the London Steelyard, HANSEATIC LEAGUE.

Steen, JAN, Dutch painter, the son of a Leyden brewer, was born in that city in 1626, went (it is believed) to Haarlem about 1644 and studied under Adrian van Ostade, joined the Leyden guild of painters in 1648, for some time carried on the trade of a brewer at Delft, and died in his native city in 1679. Steen was a painter of the same stamp as Rembrandt. A sympathetic observer of human life, he painted genre-pictures from every plane of life, the lowest as well as the highest. Although there is a decided ethnic taint in his work, it is softened by the spirit of sympathetic toleration and lightened by the play of comedy. The grave humour of his style is best seen in such pictures as the 'Doctor Visiting his Patient,' a 'Cavalier giving Lessons on the Guitar to a Lady,' 'Domestic Life,' 'Tavern Company,' 'The Oyster Girl,' 'Work and Idleness,' 'Bad Company,' 'Old Age,' and particularly the pieces of childhood (e.g. the pictures called 'St Nicholas' and 'Twelfth Night'). See the *Standy* (in German) by Rosenberg (1897).

Steenstrup, JOHANNES IAPETUS SMITH, zoologist, was born at Vang in Norway on 8th March 1813, taught on mineralogical subjects at Sorø in Denmark, and from 1845 to 1885 was professor of Zoology at Copenhagen and director of the zoological museum. His books treat principally of hermaphroditism in nature, alternation of generations, flounders' eyes, and Cephalopods. He also took a keen interest in exploring turf-moors and kitchen-middens. He died 20th June 1897. His son, JOHANNES STEENSTRUP (b. 1844), professor of Northern Antiquities at Copenhagen, has written on Viking life and times, *Nornemærne* (1876-82), and other works on Danish archaeology and ancient literature.

Steenwijk, HENDRIK VAN (c. 1550-1603), Dutch painter of architectural interiors, settled at Frankfurt in 1579.—His son HENDRIK (1580-1649) came to London in 1620, and died there.

Steeplechase, a horse-race in which hedges (called 'fences' in horse-racing language) and ditches have to be leapt by the competing horses. The first race of this kind on record took place in Ireland in 1752, from the church of Buttevant (Co. Cork) to the church of St Leger, a distance of 4½ miles. The name, however, is said to have originated in a race run in Ireland in 1803 by a merry party of fox-hunters who agreed to race in a straight line towards a steeple visible in the distance. The sport began to assume its existing

shape about the year 1831. In 1866 the Grand National Hunt Committee was formed for the purpose of laying down rules and regulations for the proper conduct of steeplechase meetings. The principal race in this class of sport is the Grand National, instituted at Liverpool in 1839, where it is still run annually; this is almost the only steeplechase which is actually partly run over a hunting country, most of the others taking place on artificial courses. The Grand Military Meeting takes place at Sandown Park, Esher. Steeplechases have always been greatly in favour in Ireland.

See *Horse-racing and Steeplechasing*, by Arthur Coventry and Alfred E. T. Watson (Badminton Library, 1889), and *Blew's History of Steeplechasing* (1900).

Steer, P. WILSON, an important representative of the New English Art Club, was born at Birkenhead in 1860, studied in France, and at first was largely influenced by the Impressionists, though later he restricted himself in choice of pigments and laid more stress on line and form. He is almost equally distinguished as a figure-painter and landscapist.

Steering. A vessel may be steered by hand, steam, hydraulic, or electric power. When on board a vessel and looking towards the bow, the right-hand side of the vessel is called the *starboard* side, and the left-hand, the *port* side (formerly called the *larboard* side). When steering by hand with a free tiller projecting forward from the rudder head, the order 'port the helm' demands that the free end of the tiller be moved towards the *port* side of the vessel, and this gave rise to the terms of the order. The rudder is by this operation swung over towards the *starboard* side of the vessel and her head turns to the *starboard* side—when going ahead. Where a wheel is used the gearing is so fitted that to 'port the helm' the top of the wheel must be turned towards the *starboard* side of the ship, and her head, as before, turns to the *starboard* side—the idea being to preserve the same result as with a free tiller. The effect of the order to 'starboard the helm' is precisely the opposite of all this. The foregoing is the British rule; but some nations obey these orders by putting the wheel the opposite way to the above, therefore to 'port the helm' the top of the wheel is turned to the *port* side and the vessel's head turns to *port*.

A 'balanced' rudder is one which has about one-third of its area before the axis about which the rudder rotates. Bow rudders, as well as stern rudders, are fitted to ferry-boats, &c. where such vessels are required to run with either end first; one rudder is locked while the other is in use. Two rudders at the stern have been tried with good effect in special cases. The adoption of twin screw-propellers (one on each side of the line of keel) has enormously increased the rapidity of steering, by working one propeller only, or by simultaneously working one ahead and the other astern. A single screw-propeller has of itself a twisting action on the hull, more especially when the propeller is going astern, the effect being to turn the ship's head the opposite way from that in which the propeller rotates. In all these cases, while it is usual to speak of the rudder, propeller, &c. turning the ship's head, the ship's stern also turns the opposite way from the direction in which the ship's head turns. For steering racing boats, see ROWING. See also BOAT, YACHT, RULE OF THE ROAD.

Steevens, GEORGE, Shakespearean commentator, was born at Stepey in 1736, the son of an East India Company director, and became a foundation at Eton and scholar of King's College, Cambridge. He was kept in hot water all his days through his meddlesome and sarcastic temper and his dishonourable habit of making bitter attacks

on his friends from behind the anonymity of newspapers like the *St James's Chronicle* and the *Critical Review*. Johnson's judgment was almost too lenient when once, in reply to Beattie's assertion 'He is very malignant,' he said, 'No sir, he is not malignant. He is mischievous, if you will. He would do no man an essential injury; he may indeed love to make sport of people by vexing their vanity.' At another time Johnson hit him off in the phrase, 'He lives like an outlaw. Another favourite trick of Steevens was to set up mock commentators, as Amner and Collins, or whom to father dirty annotations he did not wish to own. Steevens died at Hampstead, 22d January 1800, and was buried at Poplar under one of Flaxman's monuments. He began his literary life in 1766 with a reprint from the original quartos of *Twenty of the Plays of Shakespeare* (4 vols.). This work caused him to be employed as collaborator with Johnson in his edition (1773). Of this latter work a second edition appeared in 1778, to which Malone had contributed, and the latter printed in 1780 by way of supplement the doubtful plays and the poems, an act of independence which the jealous Steevens could not endure. Steevens now set to work, with the help of Isaac Reed, upon a completely new edition of Shakespeare (1793; 1803), in which 'instead of a timid and servile adherence to ancient copies,' is adopted the 'expulsion of useless and superfluous syllables, and an occasional supply of such as might fortuitously have been omitted.' This doctored text held its authority till the publication of Malone's posthumous edition, the famous *Variorum Shakespeare* (ed. by Boswell, 21 vols. 1821). In his great edition Steevens did not print the poems of Shakespeare, 'because the strongest act of parliament that could be framed would fail to compel readers into their service.'

Stefanie, or STEPHANIE, LAKE, in Abyssinia, 35 miles long and 1900 feet above sea-level, lies 50 miles east of the north end of Lake Rudolf, and like it was discovered in 1888 by Teleki and Hönlme.

Stefánsson, VILHJÁLMMUR, Arctic explorer, was born of Icelandic parentage on 3d November 1879 at Arnes, Manitoba, and educated at the state universities of North Dakota and Iowa and at Harvard, where for a time he was assistant-instructor of anthropology. After two expeditions to Iceland in 1904 and 1905, he took part in an ethnological expedition to the Eskimo of the Mackenzie delta (1906-7) and in the Arctic expedition under the auspices of the American Museum of Natural History and the Geological Survey of Canada (1908-12), a notable discovery being the Horton River, 500 miles long. In 1913-18 he headed the Canadian Arctic Expedition in its explorations north of Canada and Alaska, discovering new land north of Prince Patrick Island and west of Axel Heiberg Island, and exploring the Beaufort Sea. In 1924 he made a journey to the Macdonnell Ranges in the heart of Australia. Stefánsson's writings include *My Life with the Eskimo* (1913), *The Friendly Arctic* (1921), *The Adventure of Wrangell Island* (1925), *The Folklore of the Eskimos* (1927), and numerous contributions to scientific journals.

Steffani, AGOSTINO (1655-1730), priest, operatic composer, diplomatist, and friend of Handel, was born at Castelfranco, and served at the court of Hanover.

Steffens, HENRIK (1773-1845), born at Stavanger in Norway, studied at Copenhagen and in Germany, lectured at Kiel and Copenhagen, was professor at Halle and Breslau, and in 1832 went to Berlin. He was deeply influenced by Schelling and Schleiermacher, and in turn, and as one of the 'Philosophers of Nature,' influenced (Ehlerschläger and Grundtvig. See a work by Petersen 1874).

Stegomyia. See GNAT, YELLOW FEVER.

Stegosaurus, one of the Jurassic Dinosauria (q.v.), as big in the body as a large elephant, with the (disproportionately long) hindlegs twice as tall as a well-grown man. The forelegs, on the other hand, were not a fourth of that length, and the head (and brain) were singularly small in proportion to the animal's size. The ridge of the creature's back was diversified with a deeply segmented crest. See Ray Lankester's *Extinct Animals* (1905).

Stein, CHARLOTTE VON (1742-1827), the friend of Goethe, married in 1764 the Duke of Saxe-Weimar's Master of the Horse. Her friendship with Goethe was broken by his relations with Christiane Vulpius (1788), but renewed before her death.

See German Lives of her by Düntzer (1847) and Bode (1910), and that by Calvert (New York, 1877).

Stein, HEINRICH FRIEDRICH CARL, BARON VON, Prussian statesman, was born at Nassau on 26th October 1757. He prepared himself for public life at Göttingen (1773-77), and entered the service of Prussia in 1780. In 1804 he was summoned to take charge of the Prussian excise, customs, manufactures, and trade, but was unable then to modify the traditional methods, and resigned in 1807. After the Treaty of Tilsit Frederick-William III. had no alternative but to recall Stein, who in barely a twelvemonth wrought such changes as laid the foundations of Prussia's subsequent greatness. He abolished the last relics of serfdom, did away with the privileges of caste, freed land from the shackles of feudalism, created peasant proprietors, extirpated monopolies and hindrances to free trade, promoted municipal government, and supported Scharnhorst in his schemes of army reform. Napoleon insisted upon his dismissal, and Stein withdrew (1808) to Austria, but not before issuing his *Political Testament*. In 1812 he went to St Petersburg and forwarded the coalition against Napoleon. From the battle of Leipzig to the Congress of Vienna he was the ruling spirit of the opposition to the emperor. After the congress Stein, who was dissatisfied with its conclusions and the reaction that followed, gradually withdrew into private life. He died on 29th June 1831.

See the Lives by Pertz (6 vols. 1849-55), Seeley (3 vols. 1878), and Lehmann (1902-5).

Stein, SIR MARC AUREL, K.C.I.E., born at Binda-pet in 1862, as principal of colleges at Lahore and Calcutta carried out explorations for the government in Kashmir and elsewhere, and was made archaeological superintendent on the N.W. frontier. In 1900-1, 1906-8, and 1913-16 he made very important explorations in Chinese Turkestan, the Gobi Desert, Central Asia, and Persia. His *Sand-buried Cities* (1903), *Ancient Khotan* (1907), *Ruins of Desert Cathay* (1914), *Serindia* (1922), and other works tell how from beneath the sand he uncovered shrines, temples, sacred grottoes, watch-towers, military stations, and towns, and recovered notable MSS. and objects of art, Greco-Buddhist, Hindu, Tibetan, Chinese, and unknown scripts and types—frescoes, tablets, seals, paper documents, &c. He was knighted in 1912.

Steiner, JAKOB (1796-1863), born at Utzendorf, Bern, from 1834 was a Berlin professor, and by some 'mathematicians' was regarded as the greatest geometrical genius since the days of the Greeks. See memoir by Geiser (1874).

Steinitz, WILLIAM (1836-1900), born at Prague, was chess champion of the world 1862-94, when Lasker defeated him. He settled in America.

Steinkerk, or STEENKERKE, a village in the Belgian province of Hainaut, 5 miles N. of Soignies, was the scene of William III.'s defeat by the French under Luxembourg, 3d August 1692.

Steinle, EDUARD JAKOB VON (1810-86), born

in Vienna, became professor of art at Frankfort, and painted frescoes and oils of religious, romantic, and poetic subjects. He was influenced by Overbeck and Veit, and in turn deeply influenced Lord Leighton.

Steinlen, THÉOPHILE ALEXANDRE, born in 1859 at Lausanne, became known by his work in the illustrated French papers as a poster-designer and as a portrayer of Parisian low life. See *Steinlen and his Art* (cartoons and notes; 1912).

Steinmetz, CARL FRIEDRICH VON, Prussian general, born at Eisenach on 27th December 1796, fought through the campaign of 1813-14, winning the iron cross for valour, and in the war of 1866 routed three successive Austrian corps (June 27-29). On the outbreak of the Franco-German war of 1870 he was put in command of the right wing of the German advance; but he proved unequal to the task committed to him, especially at Gravelotte, and after that battle was nominated governor-general of Posen and Silesia. He died at Bad Landeck on 4th August 1877.

Steinthal, HEYMANN, was born at Gröbzig in Anhalt, 16th May 1823, studied philology and philosophy at Berlin, and from 1850 became a lecturer in the science of Language and Mythology. The years 1852-55 he gave to the study of Chinese at Paris, and in 1863 became an extra-ordinary professor of the science of Language at Berlin, from 1872 also lecturing at the Jewish High School on Old Testament criticism, ethics, and the philosophy and history of religion. His writings bear the stamp of a powerful intellect and of learning remarkable at once for profundity and width of range. His method shows the influence of W. von Humboldt, whose philological works he edited (1884). He died 14th March 1899.

Among his works are *Der Ursprung der Sprache* (1851); *Klassifikation der Sprachen* (1850), worked up later into the important book, *Charakteristik der hauptsächlichsten Typen des Sprachbaues* (1860); *Die Entwicklung der Sprache* (1852); *Grammatik, Logik, Psychologie* (1855); *Geschichte der Sprachwissenschaft bei den Griechen u. Römern* (1863); *Die Mundarten der Sprachen* (1867); *Allgemeine Ethik* (1885). With Lazarus he edited from its foundation in 1860 the *Zeitschrift für Volkspsychologie und Sprachwissenschaft*.

Steinway, HENRICH ENGELHARD (1797-1871; originally STEINWEG), founded a piano-factory in the town of Brunswick, but in 1850 transferred the business to New York, leaving the German branch to be carried on by the eldest son.

Stella. See SIDNEY (PHILIP), and SWIFT.

Stellaland, a short-lived South African republic, formed in 1882 by Boer adventurers, but taken over by the British and incorporated (1895) in Bechuanaland (q.v.). The chief town, Vryburg, 125 miles N., now gives name to the district.

Stellaria. See CHICKWEED.

Stellenbosch, a South African town (pop. 7000), in a fertile vine-clad valley, 25 miles E. of Cape Town by rail, with a university.

Steller's Sea-cow. See RHYNIA.

Stelvio Pass (Ger. *Stilfserjoch*), the highest carriage-road across the Alps (9042 feet), leads from Bormio in the Valtelline for over 30 miles to the Val Venosta. It was completed by the Austrian Government in 1825, but is now entirely in Italian territory. A tunnel is projected.

Stem, the ascending axis of a plant, which usually bears leaves and flowers, and maintains communication between the roots and the leaves. In the Thallophytes no stem is differentiated. Among the Bryophytes some of the Liverworts again show only a thallus. In others, and in the Mosses, stem and leaf are differentiated. The moss stem may have simple conducting elements, long thin-

walled cells, sometimes associated with strengthening elements, connecting with the midribs of the leaves. The Mosses, however, are off the main road of development, and we confine ourselves here to the stems of higher plants.

Stems vary greatly in general habit; they may be upright and unbranched as in palms, or upright and much branched as in the oak; they may be scramblers as in the bramble, or twiners as in the hop, or climbers as in the ivy and Virginian creeper; they may be prostrate as in the strawberry, or underground root-like 'rhizomes' as in the Iris. Their usual function of lifting the leaves and flowers off the ground into the fresh air and sunlight may thus be lost, or subordinated to some other function, such as storage of nutritive material, as in the 'corms' of the crocus and 'tubers' of the potato, or storage of water, as in some succulents. When the rind is green it may assimilate as leaves do, and this is very important in such stems as those of cactuses, whose leaves are reduced to spines. It may also happen that branches of the stem are modified into flattened, leaf-like phyllodes as in *Ruscus*, into thorns as in the hawthorn, into tendrils as in the vine.

The stem is in many ways markedly contrasted with the descending axis or root, but few of the distinctions are rigid. Thus, most stems have some chlorophyll, which is absent from roots except perhaps in the case of one or two of aerial habit. Stems usually bear leaves, which roots never do. The tip of a stem is almost invariably a naked-growing point, while that of a root is usually protected by a root-cap. The branches of a stem arise as superficial outgrowths (buds), while rootlets arise from rudiments which develop in an internal layer in flowering plants the pericycle. The stem has a persistent tendency to grow upwards, while the root seeks the centre of the earth, and in regard to other forces than that of gravity, stem and root usually behave in opposite ways. See PLANTS (*Movements*).

In describing aerial stems we distinguish the nodes from which the leaves arise from the intervening internodes, the buds which appear in the axils of leaves from that which forms the apex, or from those which appear arbitrarily or adventitiously, the leaf-bearing branches from the flower-stalks, and so on. The branching of the stem is usually lateral, but there are divergent forms, such as false dichotomy in the mistletoe, false axis in the vine, or true dichotomy in some Lycopods (see BRANCH).

In order to present a clear picture of the internal structure of a stem, it will be convenient to restrict our attention in the first place to the young twigs of some Dicotyledonous tree, such as the oak.

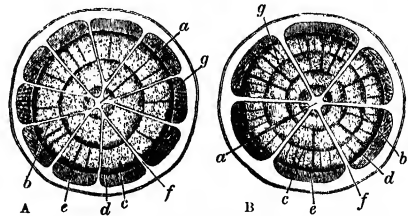

Fig. 1.—Diagrammatic cross sections of a young Dicotyledonous Stem:

A, a two-year old stem; B, a three-year old stem: a, pith; b, primary medullary rays; c, wood, in two layers in A, in three layers in B; d, cambium ring; e, bark; f, cambium (intervascular) between the bundles; g, secondary medullary rays.

Every one knows that it is easy to peel off the 'bark' and to leave the white wood bare. This is

possible because the region known as the bark is separated from the internal wood by a cylinder of delicate, readily ruptured, actively dividing cells—the 'cambium.' When a ring of bark is cut off a tree, the leaves do not wither; therefore we conclude that the water which ascends from the roots passes up by the wood. But if in the 'ringing' the young wood be also cut, the leaves wither rapidly; therefore it is by the young wood that the water ascends—a conclusion corroborated by the fact that a tree may flourish well although its heart-wood has rotted away. But the wood includes many different kinds of elements—long vessels, tracheide cells, wood-parenchyma, and wood-fibres. It is certain that the younger tracheides and vessels are the paths for the ascent of the water. Again, if we tie a string very tightly around a stem so as to compress the bark, the stem sometimes swells just above the stricture; and if there be a fruit growing from the stem on that region, it will increase greatly in weight. This suggests that the nutritive materials elaborated in the leaves pass down outside the wood. But the tissue outside the wood and the cambium cylinder includes many different kinds of elements—an external epidermis, perhaps some cork, some softer rind or cortex, a set of hard bast-fibres, and, most internally, what is called soft-bast, including long 'sieve-tubes' and also 'cambium-cells.' It is certain that this soft-bast is very important in the downward passage of elaborated sap.

If we examine—by means of thin sections—the delicate growing point of the stem, we find that it consists of an external epidermis and of an almost homogeneous 'fundamental tissue.' As we pass in our examination from the tip downwards—that is, to slightly older parts—we notice that within the fundamental tissue there gradually appear certain firm strands. These differentiations of the fundamental tissue are known as fibro-vascular bundles. 'Thus in the stem we distinguish

leaves, or, to state the fact in another way, each leaf contributes to the stem a 'leaf-trace' of fibro-vascular bundles which extend vertically down the stem, and eventually unite in a connected system. In the lower or older parts of the twig or stem there are necessarily very many fibro-vascular bundles, and these are intimately fused with one another. Almost always they are 'collateral'—i.e. the bast lies in the same radius as the wood and they are 'indefinite,' for the cambium persists. In Monocotyledons the fibro-vascular bundles which enter from the leaves pursue a curved course—first inwards and then outwards again—in the stem. In cross sections they therefore appear scattered in the fundamental tissue; they are also collateral but 'definite,' for the cambium is at an early stage used up. This last peculiarity explains the generally uniform thickness of a Monocotyledonous stem and the fact that the bark is not usually separable. In Ferns the bast surrounds the wood in each strand, forming 'concentric' bundles. So too there are structural peculiarities in the stems of Lycopods and Horsetails.

It is not easy to form an accurate conception of a stem's structure of stems, but we must have

heavy weights and resisting great strains, there is usually much *skeletal tissue*—e.g. sclerenchyma arranged in hollow cylinders, as girders, &c., and the hard wood which forms the heart of most trees. Schwendener and others have shown that the fibro-vascular bundles are always disposed to mechanical advantage. (2) As the outside of the stem is exposed to the weather and is often subjected to considerable strains, there is usually more or less *protective tissue*—e.g. the tough skin and a layer of cork. (3) As the stem mediates physiologically between the roots and the leaves, it contains *conducting tissue*—(a) the young tracheides and wood-vessels by which water and dissolved salts ascend; and (b) the sieve-tubes, cambium cells, and conducting parenchyma by which elaborated materials descend. In the pith, medullary rays, &c. these materials are often stored.

See BARK, BAST, WOOD, RHIZOME, BRANCH, BUD, PHYSIOLOGY (VEGETABLE); Kerner and Oliver's *Natural History of Plants*; and the standard text-books of botany.

Stemonaceæ, otherwise called ROXBURGHACEÆ, a family of monocotyledonous plants. The species are very few, natives of the hotter parts of the East Indies. The stems of *Stemona viridiflora*, a native of Chittagong, the Malayan Islands, &c., each a great length. The thick tuberous roots are boiled and soaked in lime-water to remove their acridity, and are then candied with sugar and taken with tea, but are considered rather insipid. The name Roxburghiaceæ was given by Sir Joseph Banks, in honour of the botanist Roxburgh.

Stencilling, a method of printing letters or

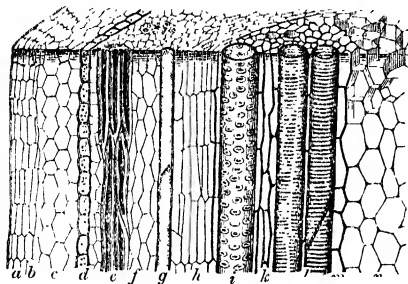

Fig. 2.—Longitudinal section of a portion of a woody Stem (after Kerner).

a, epidermis; b, cork; c, cortical parenchyma; d, bundle-sheath; e, hard-bast; f, bast-parenchyma; g, sieve-tubes; h, cambium; i, vessel with bordered pits; k, wood-parenchyma; l, vessels; m, medullary sheath; n, pith.

the epidermis, the fibro-vascular bundles, and what remains of the fundamental tissue, in the form of central pith and superficial cortex, and radiating plates or medullary rays extending between these. In Dicotyledons the fibro-vascular bundles are radially arranged, and each consists of an internal wood or xylem part, an external bast or phloem part, and between these a persistent young layer of cambium, which, by the division of its cells, adds internally to the wood, externally to the bast, and enables the stem to grow in girth. These fibro-vascular bundles are continued out into the

leaves, one piece per colour, except on the space cut out. It is much used for wall and other surface-decoration, as it is a rapid and cheap process.

Stendal, a town of Prussian Saxony, 36 miles by rail N. by E. of Magdeburg, was the former capital of the Altmark, and has a Gothic cathedral (1420-24), a Roland pillar, two old gateways, and a statue of Winckelmann, a native of the place. There are here large railway workshops and some textile industries. Pop. 30,000.

Stendhal. See BYLLE.

Stennis. See STONE CIRCLES.

Steno, NICHOLAS, anatomist and geologist, was born at Copenhagen in 1638. He was brought up a strict Lutheran, and was trained to medicine, winning great fame as an inquirer into the anatomy of the glands, the heart, and the brain. For many years he led a wandering life in Holland, France, Austria, Hungary, Italy, but in 1667 settled in Florence, and was converted to the Roman Catholic faith through the eloquence and earnestness of Bossuet. About this same period he turned his attention to geology. He was the first to point out the true origin of fossil animals; he treated of the structure of the earth's crust, clearly portraying the prevalent stratification of rocks, and discriminating between their volcanic, chemical, and mechanical modes of origination. Soon after settling in Florence he was appointed physician to the Grand duke Ferdinand II., and later added thereto the office of tutor to the son of Grand-duke Cosimo III. But his conversion gradually drew away his mind from natural science; he became a man of marked piety, was made a bishop, and in 1677 was despatched by the pope to the north of Germany to act as vicar apostolic of those regions. He died at Schwein on 25th November 1687. See Professor Hughes in *Nature* for 1882.

Stephen, saint and protomartyr; see DEACON. His festival falls on December 26.

Stephen, the name of ten popes of the Roman Catholic Church. **STEPHEN I.** was the successor of Lucius III., and his pontificate (254-257) is memorable only for his hotly maintaining against Cyprian that heretics baptised by heretics need not be rebaptised on admission into the orthodox church. A martyr according to tradition, he was canonised, his day falling on August 2.—**STEPHEN II.** died two days after his election (March 27, 752), hence he is often omitted from the list of popes.—His successor, **STEPHEN III.**, was a native of Rome. When Astolphus, king of the Lombards, threatened Rome, and the Byzantine emperor, Constantine Copronymus, left unheeded his appeals for succour, Stephen turned to Pepin, king of the Franks, who forced Astolphus to withdraw, and gave the pope the exarchate of Ravenna, the real foundation of the temporal power of the papacy. Stephen died in 757.—**STEPHEN VII.**, elected in 896, is infamous from his disinterring the corpse of his penultimate predecessor, Formosus, and throwing it into the Tiber. The year after he himself was strangled in prison.—**STEPHEN X.** was elected in 1057, under the influence of the celebrated Hildebrand, but died after eight months' rule.

Stephen, king of England (1135-54), was the third son of Stephen, Count of Blois, by Adela, daughter of William the Conqueror, and was therefore nephew of Henry I. and cousin of Matilda, daughter of Henry. He was born in 1105, came over to England at an early age, and became a favourite with his uncle, who gave him the comitship of Mortain in Normandy, while he gained that of Boulogne by marriage with its heiress, a niece of the famous Godfrey of Bouillon, and granddaughter of Malcolm and Margaret of Scotland. When his uncle Henry I. resolved to settle the crown on his daughter Matilda, whose first husband was Henry V., emperor of Germany—whence she is often styled the 'Empress Maud'—he held a council in London early in 1127, where Stephen with the rest took the

oath of fealty to Maud. A few months later the widowed empress married Geoffrey Plantagenet. On the death of Henry I. (December 1, 1135) Stephen hurried over to England from Normandy, was hailed with enthusiasm by the Londoners and the citizens of Winchester, and was crowned on the 22d of the same month. He promised many reforms, but though really a merciful and generous man he never received, or deserved to receive, confidence from his people. He attempted to strengthen his position by the unpopular policy of bringing into England bands of Fleming mercenaries, and he made enemies as fast as friends by the lavish favours he heaped upon certain of the great lords. King David of Scotland invaded the North on Maud's behalf, but suffered a severe defeat near Northallerton (1138), yet Stephen was not strong enough to do more than compromise with him by way of peace, David's son Henry being allowed to hold all Northumberland save Bamborough and Newcastle as a fief, while David kept Cumberland without homage. The first powerful enemy that the king made within England was Robert, Earl of Gloucester, an illegitimate son of Henry I., who held the strong fortress of Bristol; and next he arrayed against himself the whole power of the clergy by his quarrel with the Justiciar, Roger, bishop of Salisbury, his nephews the bishops of Ely and Lincoln, and his illegitimate son Roger the Chancellor. The realm now fell into sheer anarchy; the barons plundered and burned at their pleasure; 'men said openly that Christ and His saints were asleep.' In 1139 Matilda arrived in England, and in 1141 took Stephen prisoner at Lincoln. Matilda was now acknowledged as queen, but her harshness and greed soon disgusted Englishmen. The men of London rose, and she fled to Winchester before them. On the 1st November 1141 Stephen obtained his liberty in exchange for the Earl of Gloucester, who had fallen into the hands of his friends at Winchester, and the year 1142 saw him again in the ascendant. Earl Robert died in 1147, and the year after Matilda finally left England. Her son Henry was given the duchy of Normandy in 1149, and next year he became on his father Geoffrey's death Count of Anjou also. He married Eleanor the Duchess of Aquitaine in 1152, and now crossed over to England to pursue his ambition further. The death of his son Eustace took from Stephen all heart for prolonging the struggle, and by the peace of Wallingford and Westminster he agreed to acknowledge Henry as his successor, his continental property being secured to his remaining children, and all the 'adulterine' or unlicensed castles that had sprung up during the civil war, to the number of 1115, to be destroyed. Stephen died at Dover in October 1154.

Stephen, king of Hungary. See HUNGARY, Vol. VI. p. 4-5.

Stephen, king of Poland. See POLAND, Vol. VIII. p. 257.

Stephen, JAMES, born at Poole, in Dorsetshire, of an Aberdonian stock, in 1758, was educated at Winchester, and became successively a parliamentary reporter, an official in St Kitts, an advocate in prize cases before the Privy-council, member for Tralee, under secretary for the colonies, and a master of the Court of Chancery. He died at Bath, 10th October 1832. He was an abolitionist, and author of an able and exhaustive work on *The Slavery of the British West Indies* (1824-30).

HENRY JOHN STEPHEN (1787-1864), his son, was a serjeant-at-law, the author of a *Summary of the Criminal Law* (1834), *New Commentaries on the Laws of England* (1841), &c.—The third son, **SIR JAMES STEPHEN** (1789-1859), from Trinity Hall,

Cambridge, passed in 1813 to Lincoln's Inn, and became counsel to the Colonial Office and Board of Trade, then under-secretary of state for the colonies from 1834 to 1847, when he was knighted. From 1849 he was regius professor of Modern History at Cambridge. See the Memoir prefixed to the 4th edition of his *Essays in Ecclesiastical Biography* (1849), another well-known work by him being *Lectures on the History of France* (1851). See also his *Letters* with biographical notes by his daughter (1907).—The youngest son, SIR GEORGE STEPHEN (1794–1879), was successively a solicitor and barrister, was knighted in 1837 for his services in the reform of the poor-laws, imprisonment for debt, and the police force; in 1855 emigrated to Victoria; and like his father went on the slavery question.

SIR JAMES FITZJAMES STEPHEN, son of Sir James Stephen, was born at Kensington, 3d March 1829, and educated at Eton, King's College, London, and Trinity College, Cambridge. Taking his B.A. (1852), and called to the bar at the Inner Temple (1851), he travelled the Midland Circuit, and became recorder of Newark-on-Trent (1859–69), a Q.C. (1868), legal member of the Viceroy of India's Council (1869–72), professor of Common Law at the Inns of Court (1875–79), a K.C.S.I. (1877), and judge of the High Court of Justice (1879–91), on his retirement being created a baronet. The Indian Evidence Act was due to him; and among his works are a *General View of the Criminal Law of England* (1863); *Liberty, Equality, and Fraternity* (1873); *Digest of the Law of Evidence* (1876); *Digest of the Criminal Law* (1877); *History of the Criminal Law of England* (1883); *Story of Nincomar* (1885); and *How Subtleties* (*Saturday Review* articles, 1892). He unsuccessfully contested Harwich (1865) and Dundee (1873) as a moderate Liberal. He died 12th March 1894.—His brother, SIR LESLIE STEPHEN (born 28th November 1832; died 22d February 1904), was educated at Eton, King's College, London, and Trinity Hall, Cambridge, where he was fellow and tutor. Relinquishing orders and removing to London, he became editor of the *Cornhill* (1871–82), and of the first twenty-six volumes of the great *Dictionary of National Biography* (1885–91, from 1890 conjointly with Sidney Lee, his successor). His works include *The Playground of Europe* (1871); he was president for a while of the Alpine Club; the delightful *Hours in a Library* (3 vols. 1874–79); *History of English Thought in the Eighteenth Century* (1876); *Johnson* (1878) *Pope* (1880), *Swift* (1882), and *George Eliot* (1902) in the 'Men of Letters' series; *Science of Ethics* (1882); *lives of Paley* (1885) and his brother (1895); *An Agnostic's Apology* (1893); *Social Rights and Duties* (1896); *The English Utilitarians* (1900); *Studies of a Biographer* (1898–1902). He was made K.C.B. in 1902. See his *Life and Letters*, by F. W. Maitland (1906).

Stephens is the English name of the famous printers called Estienne or Étienne. HENRY STEPHENS (c. 1460–1520) settled in Paris about 1500. His business was taken up in 1526 by his second son ROBERT (b. 1503), having in the interval been managed by his step-father. Robert specially distinguished himself by the excellence of his workmanship, and was in 1539 and 1540 appointed printer to the king in Latin, Greek, and Hebrew. Early in life he became a convert to the doctrines of the Reformation; and on more than one occasion he got into difficulties with the theological authorities of the university of Paris for introducing editorial changes in the text of the Bibles and Testaments he printed. In 1550 indeed he found it prudent to retire to Geneva. There he remained until his death, on 7th September 1559, and published several of Calvin's works. Robert Stephens was a scholar as well as a printer; he published and printed in 1532 a Latin

dictionary (*Thesaurus Linguae Latinae*) which remained a standard work down to the middle of the 18th century. Among his editions of the Holy Scriptures the Latin New Testament of 1523, the Latin Bible (folio) of 1528, and the Greek New Testament (folio) of 1550 deserve special mention. Being a lover of the New Learning he also printed several of the classic authors, numerous Latin grammars, and similar books. Robert's brother CHARLES STEPHENS (1504–64), who graduated in medicine and practised in Paris, took charge of his brother's business when he withdrew to Geneva, and wrote and printed himself an encyclopaedic work (*Dictionarium Historicum ac Poeticum*, 1553), a collection of ancient treatises on agriculture (*Prædium Rusticum*, 1554), and other books. Robert's eldest son HENRY STEPHENS (born at Paris in 1528) worthily sustained the reputation of the family. He received an excellent education, and became celebrated for his knowledge of Greek. Both before and after he settled down at Geneva (in 1551) he travelled in Italy, England, and the Netherlands, collating MSS. (mostly Greek), and consorting with scholars. In 1556 he set up a press of his own in Geneva, and issued from it a great number of the ancient Greek authors, including some twenty 'first editions.' His greatest achievement as a scholar was a Greek dictionary entitled *Thesaurus Graecæ Linguae* (5 vols. folio, 1572), on which he spent nearly all his fortune. In his editions of classic authors he indulged in many textual emendations, most of them based on MS. authority, but some purely conjectural. From about the year 1578 he led a very restless and wandering life, and his business was greatly neglected, till at length he died at Lyons early in 1598. He also wrote his mother-tongue with force and elegance, his most remarkable production in it being the semi-satirical *Apologie pour Hérodote* (1566). The traditions of the family were kept up by PAUL (1566–1627), the son of Henry (II.) Stephens, who printed valuable editions of Euripides (1602) and Sophocles (1603); and by Paul's son ANTOINE (1592–1674), who became king's printer at Paris, and amongst other books printed the Septuagint.

See Gresswell's *View of the Early Parisian Greek Press* (1833); French works by Renouard (2d ed. 1843) and Bernard (1856); Mark Pattison's posthumous *Essays* (1889); and L. Clément's *Henri Estienne* (1899).

Stephens, ALEXANDER HAMILTON, an American statesman, was born in Georgia in 1812, admitted to the bar in 1834, and elected by the Whigs in 1843 to congress, where he sat till 1859. He advocated the annexation of Texas as early as 1838, and in 1854 defended the Kansas-Nebraska act. He at first opposed secession, but in 1861 became vice-president of the Confederacy, and in 1865 was imprisoned for five months. He sat in congress again from 1874 to 1882, was elected governor of Georgia in 1882, and died 4th March 1883. His *War between the States* appeared in 1867–70.

Stephens, GEORGE, archaeologist, was born in Liverpool, 13th December 1813, and was educated in University College, London. He settled early at Stockholm, and was appointed in 1851 lector, later professor, of English in the university of Copenhagen. His works are numerous and learned, the most important his magnificent *Old Northern Runic Monuments of Scandinavia and England* (vols. i. to iii. 1866–68–84, vol. iv. ed. Söderberg, 1901), and its abridgment, containing, however, all the engravings and translations (1884). Other works are on the Ruthwell Cross (1868), on Bugge's Studies in Northern Mythology (1883), and his early translation into English of Tegnér's *Frithiof* (Stockholm, 1841). He died 13th August 1895.

Stephens, JAMES (1824-1901), Fenian, was born at Kilkenny, son of an auctioneer's clerk with more of Saxon than of Celtic blood. He had a good education, took early to mathematics, and at twenty obtained an appointment during the making of the Limerick and Waterford Railway. He next went to Dublin, and soon became one of the most active agents of the Young Ireland party. For some years he lived mainly at Paris, where he obtained an insight into the workings of continental secret societies, and in 1853 journeyed over Ireland making himself acquainted with its condition and preparing the soil for the Fenian conspiracy. As its 'Head Centre' he exercised an enormous and despotic influence, and visited America early in 1864 to attempt to overthrow the rival schemes formed there by patriots, but was arrested in Dublin on the 10th November of the same year. Fourteen days later he made his escape from Richmond Bidwell and found his way to New York, where he was formally deposed by the Fenians. He sank into obscurity, and returned to Ireland in 1891. See O'Leary's *Recollections of Fenianism* (1896).

Stephens, JAMES, Irish poet, born in 1882, was originally a clerk in a Dublin lawyer's office. His *Insurrections* (1909) gave promise of a vigorous poet, but his later work is in a calmer spirit. Of especial note are his *Songs from the Clay* (1914), *The Demigods* (1914), *Reincarnation* (1917), *Deirdre* (1923), *Collected Poems* (1926), and a story *The Crock of Gold* (1912).

Stephenson, GEORGE, the father of the locomotive, was the son of Robert Stephenson, who again was the son of a Border shepherd in Oxnam parish, Roxburghshire, and had crossed the Cheviots in search of work at the Northumbrian coal mines. He was born at Wylam, 8 miles from Newcastle, on the 9th of June 1781, in circumstances of great poverty, his father having to maintain a family of six children on twelve shillings a week, earned by tending a colliery-engine. George's first employment was herding cows at twopence a day, from which he was promoted to hoeing turnips at fourpence; subsequently he was appointed fireman at Midmill Colliery, and at fifteen we find him at Throckley Bridge, rejoicing in a salary of twelve shillings a week. The early life of Stephenson presents a record of determined purpose, industry, and sagacity. Out of his humble gains he contrived to pay fourpence a week for lessons in reading, writing, and arithmetic, which were conned over at night, and mastered by the light of his engine-fire. As fireman he applied himself to diligent study of the steam-engine, taking his machine to pieces during his leisure hours, and thus gaining a thorough practical knowledge of it. At Black Callerton Colliery in 1801, by dint of mending shoes and cleaning watches, in addition to his regular employment, Stephenson contrived to save his first guinea. At twenty-one he had saved enough to furnish a cottage in a humble way, and on 28th November 1802, he was married to Fanny Henderson, who died in 1806, while her husband was brakesman at Killingworth Colliery. In 1815 the invention of a colliery safety-lamp, the 'Geordie,' brought his name before the public, and led to a long controversy with the supporters of Davy's Safety-lamp (q.v.). He received a public testimonial of £1000 for his discovery. In 1812 he became engine-wright at Killingworth Colliery, and it was here, by Lord Ravensworth's permission (1814), that he constructed his first locomotive, 'My Lord,' for the colliery tram-roads. At first it was not very efficient; but subsequently the grand improvement of the 'steam-blast' carried his experiment to a triumphant issue (see RAIL-

WAYS). Further improvements followed, and in 1821 Stephenson was appointed engineer for the construction of the Stockton and Darlington Railway. In 1820 Stephenson married his second wife, Elizabeth Hindmarsh, the daughter of a farmer.

The rapid growth of the trade of South Lancashire, together with the unpopular management of the Bridgewater Canal, gave rise in 1821 to the project of a railway between Liverpool and Manchester. When the bill ultimately passed, on 16th March 1826, Stephenson was appointed principal engineer, with a salary of £1000 a year. After inconceivable difficulties the line was completed in 1829. There then ensued the memorable competition of engines, resulting in the complete triumph of Stephenson's 'Rocket' (see fig. in Vol. VIII. p. 529), which, to the astonishment of every one except himself, was found capable of travelling at the till then undreamt-of rate of 35 miles an hour. 'Now,' exclaimed one of the directors, 'has George Stephenson at last delivered himself.' While occupied in carrying out the vast system of railway which soon overspread the country Stephenson's home was at Alton Grange, near Leicester; but of it he saw little, as he was often travelling on business for weeks at a time. During the three years ending 1837 he was principal engineer on the North Midland, York and North Midland, Manchester and Leeds, Birmingham and Derby, and Sheffield and Rotherham Railways; in 1836 alone 214 miles of railway were put under his direction, involving a capital of five millions; and he would sometimes dictate reports and letters for twelve continuous hours. But in the midst of his immense business his heart remained as youthful as ever. In spring he would snatch a day for bird's-nesting or gardening, in autumn nutting was still a favourite recreation; and we find him writing to his son a touching account of a pair of robins. Strong as he had shown himself when the world was all against him, he was not less so in the midst of his success. During the railway mania his offices in London were crowded every day with men of every rank and condition, eager to strengthen their prospectuses by the weight of his name. Where he disapproved—and at this time he almost always did disapprove—he invariably declined, though by acceding he might have made enormous gain; but to make money without labour or honour had no charm for Stephenson. In the autumn of 1845 he visited Belgium and Spain. On his way home he was seized with pleurisy, from which attack he seems never to have thoroughly recovered. He occupied his later years in the quiet pursuits of a country gentleman, growing fruit and indulging his love of nature. He died at his country-seat of Tipton, near Chesterfield, on 12th August 1848. In his prime Stephenson was strong and full of elastic muscular vigour, and fond of feats of strength. He read little, as his youth and manhood had been spent in hard work; and most of his letters were dictated. But he enjoyed conversation, from which most of his imparted information was derived. The leading feature of his mind was honesty of purpose, and determination in carrying it out. 'I have fought for the locomotive single-handed for nearly twenty years,' he says; 'I put up with every rebuff, determined not to be put down.' Towards trickery and affectation he never concealed his contempt, while honest merit never appeared to his liberality in vain.

See Smiles's *Story of the Life of George Stephenson* (1857; new ed. 1873); and vol. v. of his *Lives of Engineers* (George and Robert Stephenson; new ed. 1874).

Stephenson, ROBERT, only son of George Stephenson, by his first wife, was born at Willing-

ton Quay on 16th October 1803. When a boy he attended a school in Newcastle; in 1819 he was apprenticed to a coalviewer at Killingworth. In 1822 his father's improving circumstances enabled him to send Robert to the university of Edinburgh, where he remained six months, and made excellent use of his time. In 1823 we find him assisting his father in the survey for the Stockton and Darlington Railway. Subsequently he took an active part in the locomotive engine-works started by his father at Newcastle. In June 1824 he went to Colombia, in South America, on an engineering appointment, but returned at the end of three years. He then assumed the management of the Newcastle business. During the discussion as to the power to be employed on the Liverpool and Manchester line, he was in constant communication with his father, to whom his quick perception and rapid judgment were of great assistance. The result was the successful construction of the 'Rocket.' Shortly after the completion of this line he was appointed engineer of the Leicester and Swannington Railway. Subsequently he was appointed joint-engineer, along with his father, of the London and Birmingham line, the execution of which immense work was ultimately almost wholly entrusted to him. In 1829 he married Frances, daughter of John Sanderson, merchant in London. She died in 1842 without issue. The London and Birmingham line was completed in such a manner as to raise Stephenson to the very highest rank in his profession. Amongst his great achievements were the Britannia and Conway Tubular Bridges, the Victoria Bridge across the St Lawrence at Montreal, the two bridges across the Nile at Damietta, the Royal Border Bridge, Berwick, and the High Level Bridge, Newcastle, several of which are described at BRIDGE, Vol. II. pp. 446-7. In 1847 he was returned to the House of Commons as member for Whithby. He was the recipient of many honours from abroad, and was much consulted about foreign railways. He died on 12th October 1859, and was buried in Westminster Abbey. Robert Stephenson inherited the kindly spirit and benevolent disposition of his father, to whom he was ever ready to attribute the chief merit of his own achievements. 'It was his thorough training,' he once said, 'his example, and his character which made me the man I am.'

See Smiles's *Story of the Life of George Stephenson* (1873) and *Lives of the Engineers*, vol. v., and J. C. Jeaffreson's *Life of Robert Stephenson* (2 vols. 1864).

Stepney, a metropolitan and parliamentary borough in east of London (q.v., Vol. VI. p. 738), with three parliamentary divisions (Limehouse, Mile End, and Whitechapel and St George's); pop. (1921) 249,738.

Stepniak ('Son of the Steppe'), the pseudonym of an exiled leader of the Russian revolutionary party, was born in 1852 of an old Little Russian family called Kravchinsky. Sergius Mikhailovitch studied at Kieff, held a commission in the artillery, and in 1870-73 was a professor at Kieff; but having become obnoxious to the government, and believed to have been the assassin of General Mesentseff, head of the Russian police in 1878, he left Russia and settled (1876) in Geneva, and subsequently (1885) in London. He published in Russian many articles and works on the ethnography, history, folk-lore, and literature of Little Russia, and lectured and wrote for the magazines in England and America, but was best known as author of *La Russia Sotterranea* (Milan, 1881; Eng. trans. *Underground Russia*, 1883), sketches of the Nihilist movement and its leaders; of *Russia under the Tsars* (Eng. trans. 1885), a terrible indictment; and of *The Career of a Nihilist*, a novel (1889);

Russian Wit and Humour (1894); *Nihilism as it is* (1894); *King Stork and King Log* (1895). With Kropotkin (q.v.) and Lavroff, he was one of the heads of the Nihilist party. See NIHILISM. He was run over by a train near London, 23d December 1895.

Steppes, the broad plains of southern Russia and western Siberia. See DESERT.

Sterculiaceae, a family of dicotyledons closely allied to the Malvaceae and the Tiliaceae, consists of 700 species of large trees, shrubs, and herbs, natives of warm climates. The bark of some species is very fibrous, so that it is made into ropes and coarse cloth. *Sterculia fetida*, an Indian tree, with excessively fetid flowers, has pale wood, which is very durable, and susceptible of a high polish. Spars of this wood are called *Poon Spars*. The seeds of all the species are oleaginous; those of some are eatable, as those of the *Chichia* (*Sterculia Chichia* and *S. lasiantha*) of Brazil, which are about the size of a pigeon's egg, and have a pleasant flavour. They are roasted before being eaten. The Kola Nut (q.v.) of Africa is the seed of a plant of the family. The whole family agrees with Malvaceae in possessing mucilaginous and demulcent properties. The Gum Tragacanth (see GUM) of Senegal and Sierra Leone is produced by *Sterculia tragacantha*. *Brachychiton populneus*, a native of Australia, is a favourite shade-tree at Monte Carlo and other Riviera resorts. *Brachychiton rupestris*, from Queensland, has a curious bottle-shaped trunk, and is found in Italian gardens too. The Byttneriaceae or Buettneriaceae have been by some considered a separate family. The most important of this section is *Cocca* (q.v.). The fruit of *Guazuma ulmifolia* (Brazil) is eaten. *G. ulmifolia* was introduced into India, and at one time cultivated in Madras as Bastard Cedar, its foliage being used as fodder. This and numerous kindred species yield excellent bast, used for making cordage, &c.

Stere (Fr. *stère*, from Gr. *stereos*, 'solid'), the name given to the unit of cubic measure in the French metrical system. It is a cubic *Mètre* (q.v.), and equivalent to 35·3156 English cubic feet. The *decistere* is equal to 10 steres, and the *decistere* to the tenth part of a stere. This measure is much used for wood, especially firewood.

Stereoscope (Gr. *stereos*, 'solid,' and *skopein*, 'to see'). Each eye of an observer forms its own retinal image of visible objects. These two images, being taken from slightly different points of view, are slightly different from one another, as may be seen by looking at near objects with each eye alternately; and they are the more so the nearer or the narrower the objects are. These two retinal images are blended by a process of interpretation of sensation, which interpretation is based on experience, into a mental image of the object seen as a solid object possessing three dimensions. Professor Wheatstone (see also BREWSTER, SIR D.) first pointed this out in 1838, and set himself the question, 'What would be the visual effect of simultaneously presenting to each eye instead of the object itself its projection on a plane surface as it appears to that eye?' He tried the experiment with drawings of cubes, &c., and found that when one eye was made to look at each drawing the two images blended into one which appeared to stand out in relief. Photography supplies more accurate representations of views from two points of view than the artist's eye and hand can supply; and if a view be taken by two lenses upon different parts of a single sensitive plate the print from the negative must be divided into two and the two pictures transposed and mounted. If this transposition be neglected the

effect is *pseudoscopic*—i.e. instead of objects standing out in relief they stand back as if their more prominent surfaces were the walls of cavities. The stereoscope is essentially an instrument in which each picture is examined by a separate lens, and the two lenses are inclined so as to shift the images towards one another and thus to ensure or to facilitate the blending of the two images into one, besides which the lenses act as magnifying glasses. The two lenses must be equal. This may be ensured by using instead of whole lenses two halves of a single lens, the straight edges of which halves must be fixed parallel to one another.

Stereotyping is the method of duplicating or reproducing type pages cast in an alloy consisting largely of lead, but less hard than that used for ordinary type. The object of stereotyping is to save wear and tear to type, when the edition required is an unlimited one as regards the number of copies to be printed. Again, these same plates may be stored away and used for any reprints called for later on. Electrotyping (q.v.), which American printers usually prefer, is a better and more durable method, but slower and more expensive to produce.

Stereotyping was first invented by a goldsmith named William Ged, of Edinburgh, about 1725. Later on, early in the 19th century, Earl Stanhope made some further experiments with some success. Ged employed fine plaster for making the moulds, and this was diluted with water until it became creamy yet sufficiently liquid to be poured over the face of the type page, which had been previously brushed over with oil, so that the mould when dried could be easily lifted from the type surface without breaking. In releasing the cast from the mould the matrix was usually broken and of no further service. This method was generally in use until about the middle of last century, when it was superseded by the system of paper-mâché moulds, brought from the Continent, a much quicker and less expensive means of stereotyping. If the actual printing results were not quite so good, the advantage was that with care several casts could be made from the same moulds, and these could be put aside and brought into use on any future occasion to replace the first casts when worn.

The moulds employed consist of layers of a thin and special kind of tissue paper, with a thick middle sheet of softish paper which gives bulk. All the sheets are then separately pasted together with a special preparation, of which flour is the basis, with a small proportion of china clay, size, glue, or gum, which varies according to the fancy of the moulder, who pastes a final sheet of brown or other strong paper on the back to give strength to the whole. This complete substance for making the moulds is technically called 'flog,' a corruption of the French term *flan*. When finished, they are kept moist and flat under a light pressure until required. In making the mould, the type surface is usually brushed over with French chalk, so that the mould may be readily lifted when it is sufficiently dry. This flog, as it is called, is then laid on the pages to be moulded, and a damp sheet of linen is placed over it to protect the flog in beating. This is performed with a large and heavy long-handled brush until a fairly deep and even impression is made, which forms the matrix or mould. Then the type forme, with the mould still in position, is placed in the hot casting-box so that it is carefully dried and may be lifted and handled with safety. The mould is again placed in the casting-box and surrounded on three sides with brass gauges, and the fourth side left open for the hot metal to be poured in at the mouth of the casting-box. These brass gauges are usually one-sixth of an inch thick, which

regulates the thickness of the plate to be cast. As soon as the metal has cooled the lid of the box is unscrewed and the plate released from the mould. The surplus metal at the 'pour-end' of the cast is cut off and the back of the plate planed so as to give an even impression, and finished with a bevel in order that the clips may hold it fast to the blocks on which the plate is eventually mounted for printing, so as to bring it up to the requisite height of ordinary type.

Although the hand-beating of moulds is a tedious and laborious process it is still employed for the better class of book-production, hence the somewhat full description now given. The plaster method of stereotyping was generally discarded many years ago, but there was for some time a lingering demand for it in certain work, for it gave good deep plates and was more satisfactory, particularly for type music. Electrotyping has now superseded plaster stereotyping.

In order to keep pace with mechanical type-setting, and especially with machine rotary printing, various improvements have been invented for expediting moulding and stereotyping. But these apply perhaps more particularly to newspaper and magazine work, or books of long runs which are stereotyped and printed on rotary machines. Many new flogs, mostly used dry, and various moulding presses, both flat and rotary, have been introduced with the idea of expediting and cheapening production, and a brief reference to some of these will be useful to the reader.

The *Autoplate* is one that has been adopted by most newspaper houses. It is made in three sizes—the Senior, Junior, and the Pony, all of which are most useful supplements to the printing plant engaged on that class of work. It is of American origin and has been in operation for some years. It is largely automatic in its action and needs little supervision. Any number of duplicate plates of pages can be turned out in a very short space of time. The flog used is dry, and the mould itself is not beaten by hand but impressed with either a steel roller on the mangle principle or a flat press. This mould is placed in the casting machine, which is of vertical design and curved in the casting-box to the required shape of the printing cylinder on which it is to be fixed. This machine contains a cooling apparatus so that plates may be handled at once, and also a boring arch, tail cutter, and trimmer, so that the plates are delivered in a finished condition. A hand lever controls the closing and opening of the casting-box, and the action of a pedal performs the necessary finishing processes and releases the plate from the mould.

Another variation in stereotyping for newspaper work which has been introduced in even more recent times is that of the *Winkler*, which is said to be of continental origin. Its chief features are much on the same lines as the *Autoplate*, but the makers claim for it that it is very speedy in producing the curved finished plates, bored, trimmed, and bevelled ready for fastening on the cylinder of the rotary printing machines. The moulding is performed by a special kind of flat press, with a drying apparatus attached to it.

The *Ludlow* is a small and ingenious apparatus usually employed for the composing and stereotyping of various headings and displayed lines in advertisements, or work of a miscellaneous character. These lines are set up singly from matrices in a special composing-stick and then conveyed to the adjoining casting machine, which produces stereotypes cast type-high in single lines. This is a most useful auxiliary to the larger kinds of type-composing machine, and also for printers still employing the old system of hand-set composi-

tion. See also Vol. VIII., under PRINTING, in this Encyclopedia.

Partridge, *Stereotyping*; Legros and Grant, *Typographical Printing Surfaces*.

Sterility, barrenness in regard to reproduction of the species, is a term applied both to plants and animals, and may be due to external conditions, functional disorder, organic defects, or, in human beings, the results of surgical treatment. See FLOWER (*Fertilisation*), REPRODUCTION, EMBRYOLOGY, SEX, HYBRID, PUBERTY, &c. Impotency renders a marriage void; sterility in no way invalidates the marriage tie. As is well known, it frequently happens that children are born to parents who have been childless for many years.—Sterilisation for punitive purposes, for the benefit of the persons operated on, or for purely eugenic reasons, has been adopted from 1907 onwards by many American states, in the case of habitual criminals, inmates of reformatories, feeble-minded and other defective persons; but the results have not answered expectations.

Sterlet. See STURGEON.

Sterling, originally a substantive, 'a coin of true weight,' as applied at first to the English silver penny, then to all current coin. The word may be the late O.E. *sterling* ('coin with a star'), some of the early pennies bearing the imprint of a star. In the French form *esterlin* it is said to occur in the charter of a Norman abbey perhaps about the end of the 11th century. The suggestion that the name is derived from the Hanse merchants or *Essterlings* is now generally discredited. The adjective is now used of all the money of the United Kingdom and for gold and silver plate bearing the mark of assay, and has long been a synonym for pure and genuine.

Sterling, a city of Illinois, on Rock River (here crossed by two bridges, one of iron, 1100 feet long), 109 miles W. of Chicago by rail. A large dam supplies water-power to most of the fifty factories, which produce farming implements, barbed wire, pumps, windmills, wagons, paper, flour, &c.; and there are five foundries. Pop. 8000.

Sterling, JOHN, was born at Kames Castle in Bute, 20th July 1806, where his father, Captain Edward Sterling (1773-1847), was then making trial of farming. Ill-success drove him to Llanbethian, near Cowbridge, Glamorganshire, in 1809, thence to Paris, and finally to London, where he became one of the chief oracles of the *Times*. Of his seven children, John and an elder brother alone lived to grow up. John was educated at private schools, at sixteen went to Glasgow University, and at nineteen entered Trinity College, Cambridge, where he had Julius Hare as his tutor. Impulsive, quick-witted, 'able to argue with four or five at once,' he was recognised as the most brilliant member of the famous debating society—the Union—members of which were Maurice, John Kemble, Spedding, Venables, Charles Buller, and Richard M. Milnes. After a year Sterling followed Maurice to Trinity Hall, but left Cambridge without a degree in 1827. He first thought of law, but soon became busy on the *Athenæum*, which had not yet begun to flourish. A Liberal in thought and in politics, he came under the influence of Coleridge, and formed a fast friendship with General Torrijos, chief of a group of Spanish exiles. Indeed his own uncertain health and his becoming at the hour of parting engaged to Miss Barton

alone prevented his sailing on that crazy expedition which came to its inevitable close in the execution of Torrijos and Sterling's cousin Boyd at Málaga—a tragedy which haunted Sterling with a lasting horror. He married in November 1830, but soon after fell dangerously ill, and spent fifteen months in the island of St Vincent, returning in August 1832. In June of next year he met Hare at Bonn, and partly through his influence took orders, and served with characteristic zeal as Hare's curate at Hurstmonceaux for eight months. His health again giving way, he resigned, and though he sometimes for some time after, as Carlyle tells us, took duty for a friend in London, he never advanced to priest's orders; indeed, the divergence between his opinions and the church's soon widened beyond even the Coleridgean capability of accommodation. Carlyle first met him in February 1835, and his friendship with Maurice was knit still faster by the latter's marriage to Sterling's sister-in-law. He wrote for *Blackwood* and Mill's review—the *Westminster*, busied himself with projects for tragedies, one of which, *Strafford*, saw the light for a little in 1843, and wrote poems, one of which, *The Election*, was published in 1841. In August 1838 he formed the club first called the Anonymous, then the Sterling Club, among whose members were Carlyle, Allan Cunningham, C. C. Lewis, Malden, Mill, Milnes, Spedding, Tennyson, Thirlwall, W. H. Thompson, and Venables. His winters were spent abroad at Bordeaux, Madeira, or in Italy, in the vain hope of staving off his inevitable doom. In England he lived in turn at Clifton, Falmouth, and Ventnor, where he died, 18th September 1844.

Julius Hare edited Sterling's *Essays and Tales* (2 vols. 1848) with a memoir, which seemed to Carlyle so incomplete, as dwelling too exclusively on his ecclesiastical side—a brief accident in his career—that he himself determined to write his life, to give a faithful picture of his friend. The result was a masterpiece of biography which will keep the name of John Sterling from ever being forgotten.

Stern, DANIEL. See AGOULT.

Sternberg, a town of Czechoslovakia, 12 miles by rail N. of Olmutz, with cotton and linen manufactures. Pop. 13,000.

Sterne, LAURENCE, one of the greatest of English humorists, was born at Clonmel in Ireland, on the 24th of November 1713. His father, Roger Sterne, at that time an ensign in the 34th or Child-leigh's regiment of foot, was the grandson of an archbishop of York who had played an active part as a Cavalier ecclesiastic in the troubles of the previous century. Of his mother we know only that she was the daughter of a 'noted sutler' of the name of Nuttle, and the widow of a soldier, probably a comrade of her second husband. To Roger Sterne she bore seven children, of whom, however, but three survived the period of infancy. The family, continually recruited by births and reduced by deaths, accompanied their parents in the ceaseless wanderings necessitated by the father's military duties; and it was not till Laurence was eleven years old that it was found possible, or at least convenient, to give him any systematic education. He was then sent to Halifax grammar-school, where he remained for over seven years, and whence he was by the assistance of his kinsman, Simon Sterne of Elvington, sent to Jesus College, Cambridge. Here he obtained a sizarship, and in 1736, after taking his B.A. degree, he quitted Cambridge for York, where his father's brother, Dr Jacques Sterne, held, together with a goodly number of ecclesiastical offices, the archdeaconry of the diocese. Through this uncle's influence Laurence, who had been ordained three months after taking

his degree, and who took priest's orders in 1738, was presented to the living of Sutton-on-the-Forest, and then or immediately afterwards appointed a prebendary of York.

Three years later, in 1741, he married Miss Elizabeth Lumley, by whom he had two daughters. The first, born in 1745, scarcely survived its birth; the second was born and baptised 1st December 1747, and was the Lydia to whom he was all his life tenderly attached, and who published an edition of his Letters after his death. Of his life in his Yorkshire parish during the next nineteen years little or nothing is known, except that at some time, probably near the end of this period, a quarrel took place between him and his uncle, because (to quote the former's account of it) 'I would not write party-paragraphs in the newspapers; though he was a party man I was not, and detested such dirty work, thinking it beneath me.' Between 1743 and 1750 Sterne published a poem and two sermons. But in 1759 he struck a newer and truer vein in his *Political Romance*, better known as the *History of a Watch Coat*, an allegorical skit representing Sterne's contribution to a quarrel which had arisen among the clergy and officials of York Cathedral. It seems to have been very effective, for Sterne had to be persuaded to withdraw the book from circulation. Copies of the 1759 edition are very rare. It was reprinted, considerably mutilated, ten years later, and until recently this reprint was generally taken for the first edition. In 1759 he wrote the first two volumes of the work which was destined to make him famous, *The Life and Opinions of Tristram Shandy*. They appear to have been published at York towards the end of 1759, but all the first editions extant bear the date 1760, and the books were not advertised for sale in London till January 1760. The success of the new venture was immediate and signal, and Sterne at once became a 'lion' of the fashionable world. The first edition of the book was exhausted in three months. In April Doddsley brought out a second, and this was shortly afterwards followed somewhat incongruously by a volume of the *Sermons* of the 'Rev. Mr Yorick.' By the end of the year vols. iii. and iv. of *Tristram Shandy*, for which Doddsley had given £380 in advance, were already in the press, and in January 1761 they made their appearance to receive from the town as heartily amused a welcome as their two predecessors.

Meanwhile Sterne, who had in the previous year been presented by one of his new friends of rank, Lord Fauconberg, to the living of Coxwold, had transferred his residence to the parsonage of that place, which was thenceforth to be his home; and throughout the greater part of 1761 he was busy there upon the fifth and sixth volumes of his novel. They were published in December, and three weeks later Sterne, whose health, never robust, was already beginning to fail, left England for France, where he was received with high honours by the literary society of the time, and where he prolonged his stay until the summer of 1764. In January 1765 vols. vii. and viii. of *Tristram Shandy* were given to the world, and met with a more favourable reception than the two preceding volumes, the public interest in which had slightly flagged. They were followed by the publication of a second series of *Sermons* of a far more clerical character than their predecessors, and, indeed, abounding in quaint touches of their author's peculiar humour. The autumn and winter of 1765 were spent in a tour through France and Italy, which supplied the material of the work to which, in the former of those countries, he still owes his fame. The summer of the following year saw him at work again at Coxwold on the ninth and last

volume of *Tristram Shandy*, which appeared in January 1767. For three months he carried on a passionate flirtation with Mrs Elizabeth Draper—Eliza he called her—the wife of a Bombay government official. She left for India in April, but Sterne remained under the spell of the attachment, and wrote during the summer months what has been called his 'Journal to Eliza,' a kind of diary of vain longings after Mrs Draper's company. The rest of that year was occupied in the preparation of the first two volumes of *A Sentimental Journey through France and Italy*, and in the last days of February 1768 they were published. Their author's health, however, was now completely wrecked; the pulmonary malady from which he had long suffered advanced with rapid strides; and, attacked by influenza and pleurisy in the early days of March, he breathed his last in his London lodgings on the 18th of that month, his funeral taking place four days after at the Bayswater burying-ground of the parish of St George's, Hanover Square.

There have been few writers of any age or country who have displayed such mastery over every form of humour, from the lowest to the highest, as was exercised from his very first entrance into the field of authorship by this Yorkshire clergyman who never published a line till the age of forty, and who had somehow qualified himself for immediate and enthusiastic reception in the world of letters by a twenty-years' sojourn in a country parsonage. Yet, on the other hand, the imperfections of his art, and that in point not only of execution, but also of artistic conception and spirit, it is impossible to overlook. The wild eccentricity of his manner and arrangement, though it is of course a deliberate and, as a rule, it must be admitted, a highly successful bid for the laughter of the reader, was also to some extent the convenient cloak of a singularly slipshod literary style. His indecencies, if less gross than those of Swift or Rabelais, are to some by reason of their pruriency far more offensive. His passages of pathos, sometimes genuine and deeply moving, too often take the form of an artificial and overstrained sentimentalism, and degenerate from the affecting into the affected. His literary conscience had more than the laxity of his time, and he was unscrupulous in his unacknowledged borrowings from the writings of other men. Nevertheless he is, and deserves to be, a classic of English prose fiction. The extravagant Rabelaisian drollery that revels through the pages of *Tristram Shandy*, the marvellous keenness of eye, the inimitable delicacy of touch to which we owe the exquisite vignettes of the *Sentimental Journey*, might not of themselves have secured that place for Sterne; but it is for ever secured to him in right of that combination of subjective and personal with objective and dramatic humour in which perhaps he has never been excelled by any one save the creator of Falstaff. In Mr Shandy and his wife, in Corporal Trim, in Yorick, and above all in that masterpiece of truthful, subtle, tenderly humorous portraiture, 'My Uncle Toby,' Sterne has created imperishable types of character, and made their immortality his own.

Sterne's widow and daughter made about £400 by publishing three additional volumes of *Sermons* in 1769. In 1775 appeared the *Letters from Yorick to Eliza*, being an edition of ten letters from Sterne to Mrs Draper, and an edition of 115 letters (3 vols.) with an autobiographical memoir, by his daughter Lydia (Mrs Medalle), who subjected the letters to a curious system of mutilation in passages referring to her mother or to Mrs Draper. Complete editions of Sterne's works appeared in 1780 (10 vols.), 1873 (4 vols.), 1894 (6 vols.), and 1904 (12 vols.), the last, by W. L. Cross, including the previously unpublished 'Journal to Eliza.' The *Political Romance* (ed. W. L. Cross) was reprinted in 1914. As regards Sterne's

life-story, his own works are to a considerable extent autobiographical. But see also Ferriar's *Illustrations of Sterne* (1812; new ed. 1898); and *Lives* by P. Fitzgerald (1864; new ed. 1896), H. D. Traill (1882), W. Sichel (1910), Lewis Melville (1911); W. L. Cross, *The Life and Times of Laurence Sterne* (1909; new ed., containing the hitherto unpublished 'Letter-book,' 1935). The story of Mrs Draper is dealt with in *Sterne's Eliza*, by A. Wright and W. L. Selater (1922).

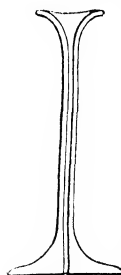

Sternhold, THOMAS, one of the authors of the English version of psalms formerly attached to the Book of Common Prayer, was born about 1500 at Awre, near Blakeney in Gloucestershire; according to Fuller and Wood, in Hampshire. He was Groom of the Robes to Henry VIII. and Edward VI., and died in August 1549. The first edition (undated) contains only nineteen psalms; the second (1549), thirty-seven. A third edition, by Whitechurch (1551), contains seven more by J. H. [John Hopkins], probably also a native of Awre, who died as rector of Great Walsingham, Norfolk, in 1570; and the complete psalms appeared in 1562, and for nearly two centuries after formed almost the whole hymnody of the Church of England. When the rival version of Tate and Brady appeared (1696) it came to be known distinctively as the 'Old Version.' Of the complete psalter of 1562, forty psalms bear the name of Sternhold, and sixty that of Hopkins. The rest were the work of William Whittingham (d. 1579), husband of Calvin's sister and Dean of Durham; Thomas Norton; William Kethe, most probably author of Psalm c. (not, however, printed here till 1565, though already in Daye's Psalter, 1560-61, and the Anglo-Genevan, 1561); J. Pnallin; J. Marekant; and Archdeacon Wsedom of Ely (d. 1568). Sternhold and Hopkins' psalms are very faithful, but somewhat coarse and homely in phraseology. As Fuller well said, its authors' 'piety was better than their poetry, and they had drunk more of Jordan than of Helicon.' See Dr Julian's magistral *Dict. of Hymnology* (1892; new ed. 1907).

Sternum. See SKELETON, RIBS, BIRD.

Sternutatories. See SNEEZING.

Stesichorus, greatest of the old Dorian lyricists, and as such called the 'lyric Homer,' was born at Himera in Sicily about 630 B.C., and died in Catania in 556. He dealt largely with epic subjects in his lyrical measures, such as the sieges of Troy and of Thebes, and was said to have been struck blind for slandering Helen. Only some thirty short fragments of his works remain, to be found in Schneidewin's *Delectus* and Bergk's *Poetæ Lyrici*.

Stethoscope (Gr. *stethos*, 'the chest,' and *skopeō*, 'I look into'), an instrument invented by Laennec (q.v.) for examining the sounds of the chest. Its simplest form will be best understood by the figure, which represents the section reduced to half the natural diameter, or one-eighth of the actual size. The upper part is the chest end, the lower the ear-piece. The latter is often made in a separate piece, for the sake of greater portability. The main object of the stethoscope being to circumscribe and localise the sounds which it transmits, the chest end should be small, in order to determine the exact seat of the greatest intensity of sound. To ascertain this, the instrument should be moved right and left, up

Stethoscope.

and down, till its end is on the exact spot from which the abnormal sound for which we are searching

—or, it may be, the absence of sound—proceeds. It may be made of wood, metal, or celluloid; it is usually made hollow as represented in the figure, but this is not necessary, as the sound is well conducted by the stem itself. But besides these rigid instruments flexible ones are largely used, particularly the *binaural* stethoscopes, which have an ear-piece for each of the examiner's ears. In these the ear-pieces and chest-piece are united by hollow tubes of india-rubber, felt, &c., whose mobility permits of much more ready adaptation to different parts and different positions of the patient's chest. The various sounds heard through the stethoscope are very important in the recognition of many diseases of the heart and lungs.

Stettin, the capital of the Prussian province of Pomerania, and one of the busiest ports on the southern side of the Baltic, stands on both banks of the Oder, 30 miles from the Baltic and 60 miles by rail (1120 by river and canal) N.E. of Berlin. The more important of the public buildings are the Gothic church of St Peter (founded 1124), the large church of St James (14th century), the old royal palace (1575), two ornamental arches, a hospital, town-house, theatre, &c. The strong fortifications were only removed in 1874; since then the ground on which they stood has been rapidly built over, so that Stettin now forms one large town with Bredow, Grabow, and Zallehow. The population rose from 76,154 in 1871 to 116,139 in 1890 and—with the suburbs—to 210,272 in 1900, and was 250,603 in 1925. Stettin is the seat of considerable industrial activity, chiefly in connection with shipbuilding, cement, sugar, paper, spirits, soap and candles, matches, clothing, oil-refining, chicory, chemicals, flour, sewing machines, bricks, machinery. The river from Stettin to the Haff was deepened to 24 feet in the early years of the 20th century. Swinemünde serves as an outer port. Stettin imports principally petroleum and other oils, rice, coffee, herrings, chemicals, groceries, cotton, seeds, iron, cement, timber, coal, oats, spirits, wool, hides. The exports embrace sugar, chemicals, metals, coal, cereals, spirits, seeds, timber, cement, and herrings. By the Treaty of Versailles (Czechoslovakia obtained the right to use certain wharves of Stettin harbour. A free haven was opened in 1898, on the east side of the Oder. A ship canal is projected, to give direct communication with Berlin. Stettin was the seat of a princely dynasty, 1107 to 1637; was occupied by Sweden, 1648-1720; by the French, 1806-13.

Steuart, SIR JAMES DENHAM, Scottish economist, was born at Edinburgh, 21st October 1712, and educated at Edinburgh University. He was admitted to the Faculty of Advocates in 1735, but spent several years in travel on the continent, returning to Edinburgh in 1740. He had met the exiled Stewarts at Rome, and, in 1745, having offered his services to Prince Charles Edward, he was sent on a mission to the court of France. After the prince's defeat, Steuart was expressly forbidden to return to Scotland, and remained till 1763 in proscription on the continent. He wrote several treatises abroad, but it was in London in 1767 that his chief work appeared, namely, the *Inquiry into the Principles of Political Economy*. This book, an 'essay on the science of domestic policy,' covered a wide field—population, agriculture, trade, industry, money, public credit, taxes, &c.—but its mercantilist attitude rendered it of little practical importance in an age that was tending to the more liberal ideas which found expression nine years later in the *Wealth of Nations*. Yet as a systematic exposition the book is perhaps not quite worthy of the complete neglect accorded it by Adam Smith in the later and greater work. Subsequent

works of his were *Considerations on the Interest of the County of Lanark* (1769) and *The Principles of Money applied to the Present State of the Coin of Bengal* (1772). By the death of an uncle, Steuart in 1773 came into possession of the estate of Westshield, and took the name Denham. He died at Edinburgh, 28th November 1780, and was buried at Cambusnethan, and a memorial was erected to him at Westminster. Steuart's works, with a memoir, six volumes in all, were published in 1805 by his son.

Stebun, FREDERIC WILLIAM AUGUSTUS, BARON, a general of the American revolutionary army, was born at Magdeburg, 15th November 1730, and at fourteen served as a volunteer under his father at the siege of Prague. By 1754 he had risen to the rank of adjutant-general, and in 1762 he was attached to the staff of Frederick the Great. While on a visit to Paris in 1777 he was induced by Count St Germain to go to America. He arrived at Portsmouth, New Hampshire, at the end of 1777, and offered his services to congress and to General Washington, by whom they were joyfully accepted; and he joined the army, then in the most deplorable condition, at Valley Forge. He was appointed inspector-general, prepared a manual of tactics for the army, remodelled its organisation, and improved its discipline. He sat on the court-martial on Major André. In 1780 he received a command in Virginia, and he took part, as major-general, in the siege of Yorktown. As generous in character as he was capable as an officer, he spent his whole fortune in clothing his men, and gave his last dollar to his soldiers. Congress made tardy reparation, and in 1790 voted him an annuity of 2400 dollars, and a township of land near Utica, New York. There he died in his log-cottage, 28th November 1794. See Sparks's *American Biography*, and a Life by Friedrich Kapp (New York, 1860).

Stebenville, capital of Jefferson county, Ohio, on the Ohio River, 68 miles below Pittsburgh (by railway 43), with blast-furnaces, rolling mills, machine and railway shops, and manufactories of iron, steel, tin, pottery, paper, glass, &c. There are bituminous coal-mines near by, and natural gas is plentiful. Fort Steuben was built here in 1787. Pop. (1920) 28,508.

Stevenage, a town of Hertfordshire, 4 miles SE. of Hitchin by rail, with an old parish church and a grammar-school (1558). Straw-plait is manufactured. Pop. 5000.

Stevens, ALFRED, decorative artist and sculptor, was born at Blandford in Dorset, the son of a country painter, in January (baptised on 28th) 1818. When he was helping his father his talent attracted the attention of certain gentlemen, who in 1833 sent him to Italy. There he remained nearly nine years studying painting, though part of the time he assisted Thorwaldsen, the sculptor, in his studio. Three years after his return home Stevens was appointed (1845) teacher of architectural drawing in the School of Design, Somerset House, London; but he held the position only three years. During the next ten years or so from that date he was busily engaged in designing and decorating, in which he displayed the highest genius and taste. He designed in all sorts of materials and for many different purposes—in silver, bronze, iron, marble, and for furniture, churches, porcelain, mantelpieces. From 1856 he laboured at the great achievement of his life, and one of the finest pieces of modelling in England in the 19th century, the monument of Wellington for St Paul's Cathedral; but owing to the greatness of his conception and plan and the inadequacy of means, it was not completed at his death, 1st May 1875. Not till 1892 was it removed from the side chapel; but in 1912 it was at last completed

(by Mr Tweed) according to Stevens's unfinished model. See SCULPTURE; and books on him by Armstrong (1883) and Stannus, *Alfred Stevens and his Work* (1892).

Stevens, THADDEUS, an American statesman, was born in Vermont in 1792, graduated at Dartmouth in 1814, was admitted to the Maryland bar, and in 1816 settled as a lawyer in Pennsylvania, where he sat in the legislature for some years. He was a Whig member of congress from 1840 to 1853, and a leader of the Republicans in the House from 1859 till his death, 11th August 1868. He was foremost in all measures for emancipating the negroes, and was chairman of the committee on reconstruction whose bill divided the southern states for a time into five military districts. In February 1868 he proposed the impeachment of President Johnson, was one of the committee which drew up the articles, and chairman of the board of managers appointed to conduct the trial.

Stevenson, ROBERT, a Scottish engineer, was born at Glasgow, 8th June 1772. His father died during his infancy; and his mother having (1786) married Thomas Smith, the first engineer of the Lighthouse Board, young Stevenson was led to devote himself to the study of engineering, in which his progress was so rapid that in 1791 he was entrusted by Smith with the erection of a lighthouse on Little Cumbrae. In 1796 he succeeded his step-father as engineer and inspector of lighthouses; and during his forty-seven years' tenure of that office he planned and constructed no fewer than twenty-three lighthouses round the Scottish coasts, employing the catoptric system of illumination, and his valuable invention of 'intermittent' and 'flashing' lights. The most remarkable of these erections was that on the Bell Rock (q.v.). In 1814 Stevenson was accompanied in his tour of inspection by Sir Walter Scott. Stevenson was also in great request as a consulting engineer in the matter of roads, bridges, harbours, canals, and railways, introduced many improvements in their construction, and occasionally co-operated with Rennie, Telford, and others. He died in Edinburgh, July 12, 1850. Stevenson left four volumes of professional printed reports, a large work on the Bell Rock Lighthouse, some articles in the *Encyclopædia Britannica* and in the *Edinburgh Encyclopædia*. See the Life (Edin. 1878) by his son, David Stevenson, C.E. (1815-86).

Stevenson, ROBERT LOUIS BALFOUR, novelist, essayist, and miscellaneous writer, was born at Edinburgh, 13th November 1850. Stevenson took great pains in tracing his genealogical descent, hoping to prove himself a Celt, but could find nothing definite before 1665, when James Stevenson, a farmer of Nether Carswell in the parish of Neilston, near Glasgow, married a certain Jean Keir. There was romance enough in the subsequent family history, and celebrity too, for Stevenson's father Thomas Stevenson and his grandfather Robert Stevenson (q.v.) were famous lighthouse engineers. His mother was Margaret Isabella Balfour, of the old Scottish family of the Balfours of Pitlig, youngest daughter of the Rev. Lewis Balfour, parish minister of Colinton, near Edinburgh. From her he inherited the delicacy which made him a chronic invalid throughout his life. His academic education was desultory, unmarked by brilliance, and sadly interrupted by ill-health. He attended various private schools and, for some eighteen months, Edinburgh Academy; then, with the intention of following the family profession, he proceeded to Edinburgh University to study engineering (1867-71). There he came in contact with Fleeming Jenkin, professor of engineering, and made what proved to be a valuable acquaintance; and

there he attained a little fame as the president of the Speculative Society; but of far greater worth than engineering knowledge to the future author of *Kidnapped* were the visits to the lighthouses of the Scottish coast, which familiarised him with Highland manners, and with the sea and sea-folk of the north. In fact, in 1871, although he had recently won a medal for a paper on lighthouse apparatus, he definitely abandoned engineering and began to read law, being admitted an advocate at the Scottish bar in 1875. But the law had little attraction for him. He had long since dabbled in authorship, and, even as a boy, his two interests had been literature and the curious study of human life in all its aspects. *The Pentland Rising*, a pamphlet, appeared anonymously from his pen in 1866, while he had also written some verse and several articles to the short-lived *Edinburgh University Magazine*, of which he was joint-editor. All the while Stevenson was an industrious student of human nature, an eager devourer and assimilator of all sorts of imaginative and historical literature, and, as he called himself, 'a sedulous ape' of the writers upon whom he had an ambition of forming his style—Montaigne, Hazlitt, Lamb, and others. From 1873 onwards numerous articles by him appeared in periodicals—the *Portfolio*, *Fortnightly Review*, *Cornhill*, *London*, &c.—and his literary talent was appreciated by the discerning. The winter of 1873-74 was spent on the French Riviera, with some benefit to his health, and about this time his work and travels brought him into contact with numerous friends who were to exercise no small influence on his future activities. Of these friends the chief were Sidney Colvin, Leslie Stephen, and W. E. Henley. In 1875, conducted thither by his artist-cousin R. A. M. Stevenson, he found his way to Fontainebleau, and for three years he paid intermittent visits to the cosmopolitan artists' colony at Barbizon. It was there in 1876 that he met a Californian lady, Mrs Osbourne, whom he afterwards married, and who was his critic and collaborator in much of his work thereafter. In 1876 he made with Sir Walter Simpson a canoe journey from Antwerp to Pontoise, the record of which, *An Inland Voyage* (1878), was his first published work. It was more or less indifferently received, but the author did not relax. In the *Cornhill* for January 1878 appeared one of the best of his earlier stories, *Will o' the Mill*, but the *New Arabian Nights*, a fantastic serial in the *London* (1878), under Henley's editorship, was less successful. There was, however, in spite of continued coolness on the part of most critics, distinct promise in his *Travels with a Donkey through the Cévennes* (1879), the journal of tour in France in the preceding autumn. At the end of 1878 Mrs Osbourne left France and returned to California. Stevenson, restless as ever, determined to follow, and follow he did in 1879 by emigrant ship and emigrant train, under the worst possible conditions for a man of his physique. In Monterey and San Francisco his fortunes came to a low ebb, and starvation, exhaustion, disease, and poverty hung around him. But his spirit refused to be daunted, and he continued writing, parts of the *Amateur Emigrant* and *A Vendetta of the West* belonging to this period. The following year (1880) he married Mrs Osbourne, who had obtained a divorce from her husband, and the couple spent a holiday at the old mining-station at Silverado, the diary of this sojourn forming the basis of the later *Silverado Squatters* (1883). They returned to Scotland in 1880, but Stevenson's health, now permanently impaired, necessitated visits of recuperation to the Highlands of Scotland, to Davos in Switzerland, and Hyères in Provence. The volume and excellence of the work he produced under these circum-

stances during the next few years are amazing. Evidently his laborious apprenticeship was now bearing fruit. *Virginibus Puerisque*, a collection of essays, which had appeared in the *Cornhill* a few years previously, was published in 1881, and next year another collection, *Familiar Studies of Men and Books*—containing his essays on Charles of Orleans, Pepys, Burns, Villon, &c.—gave the author a reputation as a fine and subtle critic. But much more important for his popularity was *Treasure Island*, the first of his romances, which, though diffidently received as a serial in *Young Folks* (1881-82), appeared very successfully in book form in 1883. It was followed by the *Black Arrow*, another serial of less enduring merit. From 1884 to 1887, following upon an illness of exceptional severity, Stevenson stayed at Bouremouth. In 1885 he published the *Child's Garden of Verses*, which he had had on hand for some years, and the somewhat singular and vociferous *Prince Otto*. The former stands almost by itself as an imaginative realisation of the make-believe and dramatising imagination habitual to childhood. About the same time he wrote a number of magazine stories, and collaborated with Henley (as he had done in 1879 in the writing of a play called *Devon Brodie*) in the fabrication of three plays, *Beat Austin*, *Admiral Gunner*, and *Mucore*, none of them being of great account. It then fell to Stevenson first to puzzle then to captivate the reading public by what he called his 'shilling-shocker,' *The Strange Case of Dr Jekyll and Mr Hyde*, a psychological story that gained immense popularity. He sealed his success with *Kidnapped*, a Highland tale contributed serially to *Young Folks* in the summer of 1886. A book on Wellington he abandoned, but his memoir on Fleeming Jenkin, who died in 1885, is a piece of good biography. In 1887 appeared three collections: one of verse, *Underwoods*; one of prose, *Memoirs and Portraits*, in which the interest is largely autobiographical; and a collected volume of stories entitled *The Merry Men*. His father died in May 1887, and his own health was so far from improving that there was every inducement to leave home. Accordingly he went to spend the winter in the dry air of the Adirondack Mountains at Lake Saranac, and never again returned to Europe. In America his fame had preceded him, and, not now the friendless immigrant of 1879, he was besieged by American editors. For *Scribner's Magazine* he wrote a series containing some of his noblest essays, appearing later in *Across the Plains* (1892), and a serial romance, the *Master of Ballantrae* (1888-89). Meanwhile had begun the memorable voyage in the Southern Pacific, one of his cherished dreams. After two years' wanderings he bought a piece of land in Samoa, and made this spot, which he called Vailima, his home for the rest of his days. In Samoa Stevenson cut a romantic figure. To the natives he was the Great White Chief, or 'Tusiata, the teller of tales.' He bestowed much attention on local politics, and in 1892 wrote the *Footnote to History* on the subject. His other writings during these years were numerous and of unequal merit. The *Letters* which he contracted to write for a New York newspaper syndicate proved a burden to him, but his tales of South Sea life, the *Island Nights' Entertainments* collection (1893) and the *Ebb Tide* (1894)—contain some really good work. *St Ives*, however, an unfinished story of the adventures of a French prisoner of war, shows weakening powers. *The Wrecker*, written, as had been the *Ebb Tide*, in conjunction with his stepson and published serially in *Scribner's* (1891-92), provides mixed fare, containing much that is excellent and much that is ineffective. *Catriona* (1893) falls below the level of *Kidnapped*, to which it is a sequel; but in the unfinished *Weir of Hermiston*, a tale of 18th-century

Scotland, Stevenson blended all that life had taught him with the best of his own genius and left his finest story of all. Mention may be made of a volume of *Ballads* (1891), and the posthumously-printed family biography, *A Family of Engineers*: also of the 'Edinburgh Edition' (28 vols.) of his works, undertaken by some of his friends (1894-98). He died suddenly on 3d December 1894, and was buried by his own desire on the top of a mountain behind Vailima.

At his death Stevenson was the most conspicuous personality in English letters, and had secured from all classes of readers an exceptional wealth of personal affection. In trying to analyse the charm which attends his memory, it is difficult, even superfluous, to separate the man and his books. For among those romances which, it may be said, have established his fame, the romance of his own life-story is as great as any. It is more than a story of adventure; it is one of determination, will-power, devotion to an ideal. Only a man with such a spirit could have come by that style of superb grace and precision, as near perfection as it seems possible to get, the result of ceaseless perseverance, though rarely betraying the fact. Coupled with this was his story-telling instinct (one of the rarest literary qualities), unsurpassed within the limits which his nature had assigned to him. Above all, it must be said, was he the master-portrayer of the romance of boyhood and adolescence, and, going still farther back, of the feelings and inner life of childhood. In verse Stevenson has been styled a brilliant amateur. At times the brilliance is well-marked, yet often his verses, always clever, seem to fall short of the one thing needful in poetry.

The *Fortuna Letters* to Sir Sidney Colvin were published in 1895, and the *Letters*, edited by Sir Sidney Colvin (1899), were supplemented by a life by Graham Balfour (2 vols. 1901). See also Henry James in *Partial Portraits* (1888), Andrew Lang in *Essays in Little* (1890), and books by Raleigh (1895), Cornford, Walt, Swinerton (1911), Miss R. Masson's *Life* (1924) and *I can Remember Robert Louis Stevenson* (1922, new ed. 1925), edited by her; J. A. Stewart's *Life* (2 vols. 1924); and a bibliography by Colonel Prédreau (1918).

Stevens Point, Wisconsin, 150 miles NW. of Milwaukee, is a railway junction and a centre of a lumbering and farming district; pop. 11,000.

Stevenston, an Ayrshire town, $\frac{3}{4}$ mile inland, and 28 miles SW. of Glasgow. Near it are collieries, ironworks, chemical works, and Nobel's explosives factory.

Stevinus, SIMON, mathematician and physicist, was born at Bruges in 1548, held offices under Prince Maurice of Orange, and died in 1620.

Steward, LORD HIGH, anciently the first officer of the crown in England (Lat. *dapifer, senescallus*), whose important functions were soon conferred on the Justiciar. The dignity, thenceforward honorary, was long hereditary in the successive houses of Leicester, but was finally absorbed into the royal dignity by Henry IV. Since that time there has been no permanent Lord Steward, but the office is temporarily revived when occasion requires, a Lord Steward being appointed under the Great Seal *pro hac vice* at a coronation or the trial of a peer. When the proceedings are at an end the Lord Steward terminates his commission by breaking his wand of office.

The Steward or High Steward of Scotland was not only chief of the household, but collected and managed the crown revenues, and took the first place in the army next to the king in battle. The office was conferred by David I. on Walter Fitzalan, the founder of the royal house of Stewart (q.v.). The accession of Robert, the seventh High

Steward, to the throne as Robert II. merged the seneschalship in the crown; but the estates of the stewards afterwards became the appanage of the king's eldest son, and by act of the Scottish parliament of 1469 the titles of Prince and High Steward of Scotland, Duke of Rothesay, Earl of Carrick, Baron of Renfrew, and Lord of the Isles were vested in the eldest son and heir-apparent of the crown of Scotland for ever. 'Great Steward of Scotland' has thus become one of the titles of the Prince of Wales.

The *Lord Steward of the Household*, in England, was originally designated the Lord Great Master of the Household. He is the head of the ancient court called the *Board of Green Cloth* (q.v.), and as such has the control and selection of all the officers and servants of the household, except those belonging to the Chapel, the Chamber, and the Stable, and also appoints the royal tradesmen. He is always sworn a member of the Privy-council, and has precedence of all peers of his own degree. He has no formal grant of office, but receives his charge from the sovereign in person, and holds his appointment during pleasure. Until 1924 his tenure of office depended upon the political party to which he belonged, but it is now non-political. The salary of the office is £2000.

Stewart, HOUSE OF. The Briton Alan Fitz-flaald (died c. 1114) got from Henry I. the lands and castle of Oswestry in Shropshire. His elder son, William Fitzalan (c. 1105-60), remaining in England, became the ancestor of the Earls of Arundel, from whom, through an heiress (1556), that earldom has passed to the Dukes of Norfolk. The second son, Walter (died 1177), coming to Scotland in the service of David I., had large possessions conferred on him in Renfrewshire, Teviotdale, Lauderdale, &c., along with the dignity of Steward of Scotland, which became hereditary in his family, and gave his descendants the surname of Stewart, by some branches modified to Stuart or the French form Stuart. The Fess Chequy (q.v.), adopted as the arms of the Stewarts, is emblematical of the chequer of the Steward's board. The connection between the Stewarts and the Fitzalans was shown by Chalmers to have been well known and acknowledged so late as 1336, when Richard Fitzalan, Earl of Arundel, for 1000 marks surrendered to Edward III. his 'hereditary right' to the Stewardship of Scotland, which was supposed to have reverted to him through the forfeiture of the Scottish line.

For seven generations the Stewardship descended without a break from father to son. Walter, the grandson of the first Steward, held in addition the office of Justiciary of Scotland, and was one of the ambassadors sent in 1239 to fetch Marie de Couci, second wife of Alexander II. His third son, Walter, called Balliol, by his marriage with the daughter of Maurice, Earl of Menteith, got that earldom, which, by his great-granddaughter, Margaret, was conveyed to Robert Stewart, Duke of Albany, son of Robert II. Alexander, fourth Steward (1214-83), was regent of Scotland in Alexander III.'s minority; he commanded at the battle of Largs (q.v.) in 1263, and, invading the Isle of Man, annexed it to the Scottish crown. From his second son's marriage with the heiress of Bonkyll sprang the Stewarts of Darnley, Lennox, and Aubigné. James, the fifth Steward (1243-1309), was one of the six regents of Scotland after the death of Alexander III. Walter, the sixth Steward (1293-1326), occupies a conspicuous place among Bruce's companions-in-arms. He did good service at Bannockburn, and four years later successfully defended Berwick against Edward II. in person. His marriage in 1315 with Marjory, Bruce's daughter, eventually brought the crown of Scot-

land to his family—'It came with aue lass,' in James V.'s well-known words. His son by Marjory, Robert, seventh Stewart (1316-90), on the death of David II. in 1371 ascended the throne as Robert II. He was twice married; first, in 1349, to Elizabeth, daughter of Sir Adam Mure of Rowallan, and secondly, in 1355, to Euphemia, Countess of Moray, daughter of Hugh, Earl of Ross. Elizabeth Mure was related to him within the prohibited degrees, so in 1347 he had obtained a papal dispensation (only discovered in the Vatican in 1789) for the marriage, legitimising those children who had already been born. Hence, in later times, the descendants of this first marriage came to be branded with the suspicion of illegitimacy, while those of the second union would boast their preferable claim to the throne. His third son, Robert (c. 1349-1420), was in 1398 created Duke of Albany; the fourth, Alexander, who in 1374 got the earldom of Buchan on the forfeiture of the Comyns, is infamous in history as the 'Wolf of Badenoch.'

Between 1371 and 1714 (343 years) fourteen Stewarts sat upon the Scottish, and six of these also on the English, throne. A race unhappy as few, they were Robert II. (1316-90); Robert III. (c. 1340-1406), who died of grief, his elder son murdered, his second an English captive; James I. (1394-1437), for eighteen years a prisoner, afterwards murdered; James II. (1430-60), killed at the siege of Roxburgh; James III. (1451-88), murdered, with his son in rebellion against him; James IV. (1473-1513), slain at Flodden—his much-loved mistress, Margaret Drummond, was poisoned; James V. (1512-42), who died broken-hearted by the rout of Solway Moss; Mary (1542-87), beheaded at Fotheringhay, thrice a widow, and for twenty years a captive; James VI. and I. (1566-1625); Charles I. (1600-49), beheaded; Charles II. (1630-85), for fourteen years an exile; James VII. and II. (1633-1701), for twelve years of his youth an exile, and again for the last twelve of his old age; and Mary (1662-94) and Anne (1665-1714), his daughters, who supplanted him, and both died childless. Thus five of the fourteen met with a violent death; two died of grief; and eight succeeded as minors. All the above receive separate articles; but here may be noticed the son and the grandsons of James VII. and II.

By his second queen, Mary of Modena, James had one son, JAMES FRANCIS EDWARD, born at St James's Palace on 10th June 1688. Forty-two privy-councillors, ladies of rank, &c. (more than half of them Protestants) were present in the bed-chamber; but the warning-pan fiction fastened on him the nickname of Pretender. Six months later he was conveyed by his fugitive mother to St Germain, where his boyhood was passed, and where, on his father's death in 1701, he was proclaimed his successor. In an attempt, in March 1708, to make a descent upon Scotland, the young 'Chevalier de St George,' as he was styled by his adherents, showed some gallantry, but was not suffered to land; and after his return he served with the French in the Low Countries, at Malplaquet charging twelve times, and in the last charge receiving a sword-thrust in the arm. But in Mar's ill-conducted rebellion (see JACOBITES) he showed himself heavy, spiritless, even fearful, when, too late in the day, he landed at Peterhead (22d December 1715), and sneaked away six weeks afterwards from Montrose. France was now closed to him by the treaty of Utrecht, and almost all the rest of his fainéant, prayerful life was passed at Rome, where he died on 1st January 1766. In 1719 he had married the beautiful and high-spirited Princess Clementina Sobieski (1702-35) who bore

him two sons, but was much irritated by his preference for the titular Countess of Inverness.

See books on him by Martin Haile (1907) and Alice Shield (1907).

His elder son, CHARLES EDWARD LOUIS PHILIP CASIMIR, known variously as the 'Young Pretender,' the 'Young Chevalier,' and 'Bonny Prince Charlie,' was born at Rome on 31st December 1720. His education was irregular, but from childhood he raised the hopes of the Jacobites by the promise of a bright and chivalrous nature. He first saw service at the siege of Gaeta (1734); fought bravely at Dettingen (1743); and next year repaired to France, to head Marshal Saxe's projected invasion of England. But the squadron which was to have conveyed the transports with 15,000 troops to Kent fled before the British fleet; the transports themselves were scattered by a tempest; and for a year and a half Charles was kept hanging on in France, until at last, sailing from Nantes, he landed with seven followers at Eriska in the Hebrides on 2d August 1745, and on the 19th raised his father's standard in Glenfinnan. The clansmen flocked in; on 17th September Edinburgh surrendered, though the castle still held out; and Charles held court at Holyrood, the palace of his ancestors. There followed the victory over Sir John Cope at Prestonpans (q.v.), the march upon London with 6500 men, the fatal turning at Derby (6th December), the victory over Hawley at Falkirk (17th January 1746), the crushing defeat by the Duke of Cumberland at Culloden (16th April), and Charles's five months' hidings and wanderings, with £30,000 set on his head, in the Hebrides and the western mainland, till on 20th September he got shipping from Moidart to Brittany. The peace of Aix-la-Chapelle (1748) caused his forcible expulsion from France, and thereafter he lived successively at Avignon, Liège, Basel, Florence, and Rome. He seems to have paid two or three secret visits to London between 1750 and 1760; in 1766 succeeded to his father's empty titles; in 1772 married the ill-fated Countess of Albany (q.v.); and for forty years a miserable drunkard, died at Rome, 31st January 1788. By his Scottish mistress, Clementina Walkenshaw, he left a natural daughter, Charlotte (1753-89), whom he had created Duchess of Albany. He was buried at Frascati, but translated to St Peter's.

See also COPE (SIR JOHN), CULLODEN, and MACDONALD (FLORA); Ewald's *Life of Prince Charles Edward* (1875), and A. Lang's (1900 and 1903).

His brother, HENRY BENEDICT MARIA CLEMENT, Duke of York, Cardinal, and Bishop of Frascati, was born at Rome, 5th March 1725. After the failure of the '45, when he had hastened to Dunkirk to support Prince Charles Edward, he resolved to take orders, and in 1747 received a cardinal's hat from Benedict XIV. Clement XIII. consecrated him Bishop of Corinth *in partibus*, and subsequently appointed him to the suburban see of Frascati, where he took up his residence. He enjoyed, through the favour of the French court, the revenues of two rich abbeys, as well as a Spanish pension; and the liberal charity with which he dispensed his income endeared him to his flock. On his brother's death in 1788 he caused a medal to be struck, bearing the Latin legend, 'Henry IX., king of England, by the grace of God, but not by the will of men.' The French Revolution stripped him of his fortune, but in 1796 he sold his family jewels to relieve the necessities of Pius VI. In 1798 the French plundered his villa, and he had to flee for his life to Venice. He returned in 1801 on the restoration of the papal authority, George III. having meanwhile in 1800 granted him a pension of £4000. This last, perhaps, best, of the Stewarts died at the age of eighty-two on 13th July 1807. The crown-jewels, carried off

from England by James II., were bequeathed by him to George IV., then Prince of Wales, who in 1819 caused Canova to erect a monument in St Peter's to 'James III., Charles III., and Henry IX.'

See H. M. Vaughan, *The Last of the Royal Stuarts* (1906).

Next to the exiled Stuarts in representation of the royal house as heir-of-line came the descendants of Henrietta (q.v.), Charles I.'s youngest daughter, who in 1661 was married to Philip, Duke of Orleans. From this marriage sprang Anne Mary (1669-1728), who married Victor Amadeus, Duke of Savoy (q.v.) and king of Sardinia; their son, Charles Emmanuel III. (1701-73), king of Sardinia; his son, Victor Amadeus III. (1726-96), king of Sardinia; his son, Victor Emmanuel I. (1759-1824), king of Sardinia; his daughter, Mary (1792-1840), who married Francis, Duke of Modena; their son, Ferdinand (1821-49), who married Elizabeth of Austria; and their daughter, Maria Teresa (born 1849), who in 1868 married Prince Ludwig of Bavaria (1845-1921; king 1913-18), and whom, as 'Mary III. and IV., the 'Legitimist Jacobites' of 1891 put forward as the 'representative of the Royal House of these realms.' Rupert, her son, was born at Munich on 18th May 1869, and is ninth in descent from Charles I.

The branch of the family which the Act of Settlement (1701) called to the throne on the death of Queen Anne were the descendants of the Electress Sophia of Hanover, granddaughter of James VI. and I. by her mother, the Princess Elizabeth (q.v.), Electress Palatine and Queen of Bohemia. By that act not only were the above-mentioned descendants of Charles I.'s daughter, Henrietta of Orleans, excluded, but also the Roman Catholic descendants of the Princess Elizabeth's sons. King George V. is twenty-fourth in descent from Walter Fitzalan, eighteenth from Robert II., and tenth from James VI. and I.

Before proceeding to glance at the cadets of the House of Stewart we may notice here ARABELLA STUART, who, born in 1575, was the daughter of the Earl of Lennox, Darnley's younger brother, so a great-great-granddaughter of Henry VII., a third cousin to Queen Elizabeth, and a first cousin to James VI. and I. She lost her father at two, her mother at six, and was brought up by her maternal grandmother, the imperious Bess of Hardwick. At the age of twenty-seven, shortly before Elizabeth's death, she was suspected of having a lover in the boy William Seymour, who had Tudor blood in his veins; but on James's accession she was restored to favour, only, however, to contract a secret marriage in 1610 with him. Both were imprisoned, and both escaped—Seymour successfully to Ostend, she unsuccessfully in man's attire, for she was retaken in the Straits of Dover. She died, insane, in the Tower of London, 25th September 1615.

See Lives by Elizabeth Cooper (2 vols. 1866), Mary E. Bradley (2 vols. 1889), B. C. Hardy (1913), Lefuse (1913).

The cadets of the house may be divided into four classes: (1) descendants of Robert II.; (2) descendants of natural sons of his descendants; (3) descendants of natural sons of Stewart kings; and (4) legitimate branches of the Stuarts before their accession to the throne. To the first belong the Stuarts of Castle-Stewart, descended from Robert, Duke of Albany, Robert II.'s third son, through the Lords Avondale and Ochiltree. They received the titles of Lord Stuart of Castle-Stewart in the peerage of Ireland (1619), Viscount Castle-Stewart (1793), and Earl (1800). To the second class belong the Stuart Earls of Traquair (1633-1861), descended from a natural son of James Stewart, Earl of Buchan. To the third class belong the Regent Moray (q.v.), the Marquis of

Bute, and the Shaw-Stuarts; and to the fourth belong the Earls of Galloway (from a brother of the fifth High Stewart), the Lords Blantyre, the Stuarts of Fort-Stewart, and the Stuarts of Grandtully (from the fourth High Stewart; the last baronet died in 1890).

See, besides works cited at JACOBITES, under the different Stewart sovereigns, and in Marshall's *Genealogical's Guide* (new ed. 1903), Stewart genealogies, &c., by Symson (1712), Hay of Drumboote (1722), Duncan Stewart (1739), Noble (1795), Andrew Stuart of Castle-milk (1798), A. G. Stuart (for Castle-Stewart branch, 1854), Sir W. Fraser (for Grandtully branch, 1868), W. A. Lindsay (1888); William Townend, *History of the Descendants of the Stuarts* (1858); the Marchesa Campana de Cavelli, *Les Derniers Stuarts à Saint-Germain en Laye* (2 vols. 1871); Percy M. Thornton, *The Stuart Dynasty* (1890); Gibb and Skelton, *The Royal House of Stuart* (1890), illustrating the Stuart exhibition (1888); Hewison, *Bute in the Olden Time* (1894-95); J. J. Foster, *The Stuarts in Art* (2 vols. 1902).

Stewart. ALEXANDER TURNEY, millionaire, was born of Scottish stock at Lisburn, near Belfast, in 1803, emigrated to New York in 1823, and two years later opened his first dry-goods store in Broadway, with a rent of \$250; his retail store built in 1862 cost nearly \$2,750,000. His charities were numerous and bountiful; yet at his death, 10th April 1876, he left some \$40,000,000, which there were no blood relatives to share. See RESURRECTIONISTS, and GARDEN CITY.

Stewart. BALFOUR, LL.D., F.R.S., physicist, was born at Edinburgh, November 1, 1828. He studied at both St Andrews and Edinburgh universities, but in 1846 entered on a commercial career. Seven years later he forsook business, returned from Australia to Edinburgh, and became assistant to Professor Forbes. In 1859 he was appointed director of the Kew Observatory, and in 1870 professor of Physics at Owens College, Manchester. He died, December 19, 1887, near Drogheda, Ireland. He made his first reputation by his work on Radiant Heat (1858), by which he established the equality of the emissive and absorptive powers of bodies. He is rightly regarded as one of the founders of the method of spectrum-analysis, of which the complete theory was given by Kirchhoff a little later (see HEAT and SPECTRUM). In connection with his work on radiant heat the experiments (in conjunction with Professor Tait) on the heating of a rotating disc in vacuo (1865-78) should be mentioned, as should also his remarks on the effect of relative motion on radiation. His other labours were chiefly meteorological, his name being specially associated with such subjects as the relation between sun-spots and temperature and magnetic changes, terrestrial magnetism, and the daily ranges of the meteorological elements. Particularly valuable are his numerous papers on terrestrial magnetism. As a writer of text-books on physics he earned a high reputation, the *Treatise on Heat* (1866), the *Elements of Physics* (1870), and the *Conservation of Energy* (1873), all running into numerous editions, as was also the case with *The Unseen Universe, or Physical Speculations on a Future State*, a book published conjointly by Stewart and Professor Tait in 1875.

Stewart. SIR CHARLES. See CASTLEREAGH.

Stewart. DUGALD, philosopher, was born in Edinburgh on the 22d November 1753, and was the son of Matthew Stewart (q.v.). He entered the High School in his eighth year, and remained till his thirteenth. His subsequent course at the university extended from 1765 to 1789. In the departments of study where his own career afterwards lay he was fortunate to find pro-

fessors of ability and distinction, the moral philosophy chair being occupied by Adam Ferguson. While Stewart gave his highest promise in these subjects he also made great attainments in mathematics and natural philosophy, and likewise in classics. In 1771 he went to study at Glasgow, partly with a view to one of the Snell scholarships at Balliol College, Oxford, and partly to attend the lectures of Dr Reid. It was while there that he wrote an essay on Dreaming, which was his first effort in mental philosophy, and contained the germs of many of his subsequent speculations. He lived in the same house with Archibald Alison, the author of the *Essay on Taste*, and the two became intimate friends through life. He was at Glasgow only one session. In 1772, in his nineteenth year, he was called upon by his father, whose health was failing, to teach the mathematical classes in the university of Edinburgh; in 1775 he was elected joint-professor, and acted in that capacity till 1785. In 1778 Adam Ferguson was absent from his post on a political mission to America, and Stewart taught the moral philosophy class in addition to his mathematical classes. The lectures that he gave on this occasion were wholly his own, and were delivered from notes, as was his practice in after years. On the resignation of Ferguson in 1785 he was appointed professor of moral philosophy, and continued in the active duties of the class for twenty-five years. His lectures were greatly admired and numerously attended. He went over a wide compass of subjects: psychology, or the science of mind proper, metaphysics, logic, ethics, natural theology, the principles of taste, politics, and last of all, political economy, which, from the year 1800, he treated in a separate course. In 1792 appeared his first volume of the *Elements of the Philosophy of the Human Mind*, and in 1793 he published his *Outlines of Moral Philosophy*. He read before the Royal Society of Edinburgh in 1793 his *Account of the Life and Writings of Adam Smith*; in 1796 the *Account of the Life and Writings of Principal Robertson*; and in 1802 the *Account of the Life and Writings of Dr Reid*. In 1805 he took a prominent part in the 'Leslie controversy,' and wrote a pamphlet maintaining Sir John Leslie's claims to the chair of mathematics and defending him from theological aspersions. In 1806, on the accession of the Whig party to power, he received a sinecure office worth £300 a year. The death of his second son in 1809 gave a blow to his health, otherwise indifferent, and he was unable to lecture during part of the following session; Dr Thomas Brown, at his request, acting as his substitute. The following year Brown was appointed conjoint professor, and taught the class till his death in 1820. From 1809 Stewart lived at Kinneil House, near Bo'ness, which the Duke of Hamilton had placed at his service. In 1810 he published his *Philosophical Essays*; in 1814 the second volume of the *Elements*; in 1815 the first part, and in 1821 the second part, of the *Dissertation on the History of Ethical Philosophy*; in 1827 the third volume of the *Elements*; and in 1828, a few weeks before his death, the *Philosophy of the Active and Moral Powers*. On the death of Brown Stewart exerted himself to secure the appointment of Sir William Hamilton to the chair, but the influence used with the town-council in behalf of John Wilson ('Christopher North') was overpowering. Stewart resigned his conjoint professorship on the 20th June 1820; he died 11th June 1828.

The philosophy of Stewart was the following up of the reaction commenced by Reid against the sceptical results that Berkeley and Hume drew from the principles of Locke (see SCOTISH PHILOSOPHY). Hence arose the principles of common

sense of Reid, in which Stewart for the most part acquiesced. Stewart also followed and improved upon Reid in the systematic exposition of all the powers of the mind which rendered mental philosophy for the first time a subject of study, independent of metaphysical, logical, and ethical applications; although he also followed it out in all these directions with his usual perspicacity and felicity of exposition. His contributions to the philosophy of taste, in the *Philosophical Essays*, are among the best parts of his writings. Although Stewart was not one of the most original thinkers in his department, yet, by the force of his teaching and the compass of his writings, he did much to diffuse an interest in the speculations connected with the human mind. Amongst notable men who studied under Stewart were Lords Jeffrey and Cockburn, Sir Walter Scott, Lord Brougham, Francis Horner, Sir James Mackintosh, James Mill, Lord Palmerston, and Earl Russell.

His works (11 vols. 1854-58) were edited by Sir W. Hamilton, whose work was completed and the biography added by Professor Veitch.

Stewart, MATTHEW, was born in 1717 at Rothesay in Bute. He studied first at the university of Glasgow, where he was a favourite pupil of Robert Simson, and in 1742-43, when he was a student of divinity in the university of Edinburgh, attended Maclaurin's lectures on fluxions. For a short period he was minister of Rosneath, and in 1747 was elected Maclaurin's successor. He had in a previous year published his *General Theorems of considerable use in the higher parts of Mathematics*. In 1761 he published *Treats Physical and Mathematical*, and in 1763 his *Propositions Geometricæ more veterum demonstratæ*. In 1772 he ceased to lecture in the university, and he died on 23d January 1785. The lifelong friendship which existed between him and Simson was unusually cordial, and it is highly probable that the bent of Stewart's mind towards the ancient geometry and his comparative indifference to the modern analysis were due to the example of his master. A biographical account of Stewart by Professor John Playfair will be found in the first vol. of the *Transactions of the Roy. Soc. of Edinburgh* (1788).

Stewarton, a town of Ayrshire, on Annick Water, 5½ miles N. by W. of Kilmarnock. Its specialty is the Scotch bonnet manufacture; but it also carries on carpet-weaving, spindle-making, &c. Pop. 4000.

Stewartry, the name which was given in Scotland to a district governed by a steward, an officer appointed by the king with jurisdiction over crownlands, and powers similar to those of a lord of regality. While the civil jurisdiction of a steward was equivalent to that of a sheriff, his criminal jurisdiction was much more extensive. The only remaining trace of this jurisdiction exists in the term Stewartry, which in place of county is applied to the district of Kirkcubright (q.v.; and see GALLOWAY).

Stewing, in Cookery, a very economical way of preparing meat and fruits for food. It differs from boiling in this respect, that only a small quantity of water is used, and the heat applied is so gentle as only to *simmer* it. The more slowly the ebullition is carried on the better. As the small quantity of water is retained as gravy, nothing is lost. Meat prepared in this way is tender and savoury, but, owing partly to the richness of the gravy, is not very digestible. See COOKERY, DIGESTION.

Steyer, a town of Upper Austria, at the confluence of the Steyer and Enns, 36 miles by rail S. by E. of Linz, is the chief seat of the iron and steel manufactures of Austria, turning out firearms, cutlery, files, nails, chains, &c.,

and also manufacturing paper, leather, beer. Pop. 20,000.

Steyn, MARTINUS THEUNIS (1857-1916), born at Winburg in the Orange Free State, studied at Grey College, Bloemfontein, and the Inner Temple, London, practised as a barrister in Bloemfontein was State Attorney of the Orange Free State (1888) and a judge. In 1896 he was elected president of the Orange Free State, which under his administration entered the war of 1899-1902 on the side of the Transvaal. He promoted the Union of 1910, but was subsequently lukewarm.

Steyning, a town of Sussex, 1 mile W. of the river Adur and $4\frac{1}{2}$ miles N. of Shoreham. Til 1832 it returned two members.

Sticking-plaster. See PLASTERS.

Stickleback (*Gasterosteus*), a genus of Acanthopteroan fishes having the dorsal fin replaced by strong spines which vary in number in the different species. The sticklebacks are small and the male is brightly coloured, the brightness increasing at sexual maturity. They are widely distributed throughout northern and temperate regions. One of the European species, the Fifteen-spined Stickleback (*G. spinacanthus*), is marine; the other two - the Ten-spined Stickleback (*G. pungitius*) and the Three-spined Stickleback (*G. aculeatus*) - occur in fresh or brackish water.

Stickle-backs and Nests.

Much interest attaches to the sticklebacks on account of the high degree of parental care exhibited by the male. At the spawning season he constructs a nest of grass and stems of plants firmly cemented together by mucous threads secreted from the kidneys. The nest is barrel shaped, and has at first one aperture. The work of building ended, the eager male, now resplendent in his wedding-robes, sets forth in search of a mate, whom he coaxes to his nest. After she has quitted it, making a second aperture, he enters, fertilises the eggs, and immediately resumes his quest, bringing home another and another mate until the nest is filled with eggs. These eggs he guards with jealous vigilance, freeing them from parasites, and attacking every enemy that comes within reach, even though it be a fish many times larger than himself. With the hatching of the ova his labours become for a time more arduous than ever, for the tiny, active sticklebacks must be guarded until they are big enough and strong enough to fend for themselves.

Stieler, ADOLF, editor of the well-known *Atlas* (Gotha, 1817-23; 75 plates, enlarged in succeeding editions to 108), was born at Gotha on 26th February 1775, and died at the same place on 13th March 1836, having spent his life in the public service of the duchy. A *School Atlas* and a *Map of Germany* (in 25 sheets) by him were also very popular.

Stier, RUDOLF EWALD, German theologian, was born at Fraustadt, 17th March 1800, studied at Jena, Halle, and Berlin, and had already laboured as pastor at Frankleben near Merseburg and Wichlinghausen in the Wupperthal when he was appointed in 1850 superintendent at Schkenditz, and in 1859 at Eisleben, where he died, 16th December 1862. Stier was a man of fervent and somewhat

mystical piety, and as an exegete he shows absolute faith in the inspiration and infallibility of his text; but he has no other dogmatisms, and his books are full of observations always ingenious and edifying, if sometimes prolix and far-fetched.

Among his works the most popular have been *The Words of the Lord Jesus* (Eng. trans. 8 vols. 1855-58), *Words of a True Saviour* (trans. 1859), *Words of the Angels* (1862), and *Words of the Apostles* (trans. 1869). See the Life by his sons (Wittenberg, 1868).

Stiff Neck. See NECK.

Stifter, ADALBERT, German prose-writer, was born at Oberplan in the Böhmerwald, 23d October 1805, and studied at Vienna. After a tutorship in the Mettenich family he became in 1849 a school-inspector at Linz, and died 28th January 1868. His fame rests mainly on the beauty of his prose and his feeling for nature in *Studien* (1844-50) and *Bunte Steine* (1852); but Hermann Bahr declares *Der Nachsommer* (1857) to be 'our Austrian *Wilhelm Meister*,' and *Wittiko* (1864-67) the only work of its kind since *I Promessi Sposi*.

Stigand, Archbishop of Canterbury, enjoyed great favour with Edward the Confessor, who made him his chaplain, then (1044) Bishop of Elnham or of the East Angles. Eight years later the bishop mediated successfully in the interests of peace between the king and Earl Godwin, and was rewarded with the archbishopric of Canterbury, which had been abandoned by Archbishop Robert. But his appointment was generally looked upon as uncanonical, and was still so regarded even after Stigand received the pallium from Pope Benedict X., Benedict's own election being held to be illegal. On the death of Harold, Stigand gave his vote for Edgar Atheling to be king, and for this reason, and because he was a firm friend of the House of Godwin, William the Conqueror hounded him, and induced the pope to send a commission of cardinals, who deprived him of his dignities and sentenced him to perpetual imprisonment. But Stigand died shortly afterwards at Winchester; it is said he was starved to death, though whether voluntarily or under compulsion is uncertain.

Stigma. See FLOWER.

Stigmata, the root of *Sigillaria* (q.v.) and other trees.

Stigmatisation (Lat. *stigmatizatio*, 'a puncturing,' from Gr. *stigma*, 'a puncture'), the name applied by Roman Catholic writers to the supposed miraculous impression on certain individuals of the 'stigmata,' or marks of the wounds which our Lord suffered during the course of His Passion. St Paul says of himself, 'I bear in my body the marks of the Lord Jesus' (Gal. vi. 15), but his bold metaphor is most likely taken from the notion of soldiers branding on their bodies their general's name. In the early days many Christians branded the name of Christ on their foreheads, and various voluntary mutilations for Christ's sake were practised by enthusiasts. The stigmata comprise not only the wounds of the hands and feet, and that of the side, received in the crucifixion, but also those impressed by the crown of thorns and by the scourging. The impression of the stigmata is by those who believe in its reality regarded as a mark of the signal favour of our Lord, manifested to believers specially devoted to the contemplation of His Passion. The most remarkable example of stigmatisation is that said to have occurred in 1224 to Francis of Assisi, on the mountain of Alverno. Being absorbed in rapturous contemplation of the Passion of Christ, he saw a seraph with six shining wings, blazing with fire, and having between his wings the figure of a man crucified,

descend from heaven and approach him, so as to be almost in contact. After a time the vision disappeared, the soul of Francis filled with reverence and awe. And now he became aware that in hands, feet, and side he had received externally the marks of crucifixion. These mysterious marks continued during the two years until his death, and are claimed to have been seen by many eye-witnesses, including Pope Alexander IV.

The Dominicans openly disputed the fact, but at length made the same claim for Catharine of Sienna, whose stigmata were explained as at her own request made invisible to others. The Franciscans appealed to Sixtus IV., and that pope, himself a Franciscan, forbade representations of St Catharine to be made with the stigmata. Still the fact is recorded in the breviary office, and Benedict XIII. granted the Dominicans a special feast in commemoration of it. Many others, especially women, are claimed to have received all or some of the stigmata. The last to be canonised (1831) for this reason was Veronica Giuliani, who is said to have received in 1694 first the marks of the crown of thorns, and afterwards those of the crucifixion. More recent cases are those of Anna Katherina Emmerich (1774-1824), who became a nun at Aqnetenberg; 'L'Estatista' Maria von Morl of Caldaro (1839); Louise Lateau (1850-83, in 1868), whose stigmata were stated to bleed every Friday; and Mrs Girling (1827-86, about Christmas 1864), of the New Forest Shaker community. Dr Inbert in 1894 enumerated 321 persons, of whom but 41 were men, as having received the stigmata, and of these 80 lived before the 17th century. Apart altogether from the question of the value of the evidence offered, we may reasonably conclude that some kind of stigmatisation is a pathological condition of occasional occurrence, but from this to the assertion that it is a special sign of divine favour is a wide and an unwarrantable leap.

Stilbite. See ZIOLITE.

Stilfserjoch. See STELVIO.

Stilicho, a famous Roman general, the mainstay of the western empire after the death of Theodosius the Great, is said to have been a Vandal, and was born about 359. Through his courage and ability he rose rapidly in rank, was sent as ambassador to Persia in 384, and soon after his return rewarded with the hand of Serena, niece of Theodosius. His rise caused a jealousy that soon grew to rankling hatred in the heart of Rufinus, the ambitious minister of Theodosius. In 394 Stilicho departed for Rome in charge of the youthful Honorius, who had been committed to his care, placed him on the throne of the western empire, and administered in his name the affairs of state. On the death of Theodosius (end of 394) Rufinus, the guardian of Arcadius, instigated Alaric to invade Greece while Stilicho was engaged in chastising the invaders of the Roman territories on the Rhine and in Gaul. Returning, he at once set out for Constantinople and destroyed Rufinus, then marched against Alaric, blocked him up in the Peloponnesus, but through over-confidence permitted him to escape across the isthmus with his captives and booty. In 398 his daughter Maria became the wife of Honorius. His old opponent, Alaric, after several inroads upon the eastern provinces of the western empire, now invaded Northern Italy, but was signally defeated at Pollentia (403) and Verona by Stilicho, who had hurriedly called in the Roman legions from Rætia, Gaul, Germany, and even Britain. Stilicho's ambition now led him to attempt the introduction of his own family to the imperial succession—a state-

ment disbelieved by Gibbon, who considers it merely as an invention of the crafty Olympius—by the marriage of his son with the heir-presumptive Placidia, the daughter of Theodosius, and to attain this end he made overtures of alliance to Alaric, which were gladly accepted. But the dreadful inroad of Radagaisus (406) at the head of more than 200,000 (some say 400,000) barbarians, who ravaged the whole country as far as Florence, compelled the great general of the West to shelve for a time his ambitious schemes. With a small but chosen army of veterans, aided by a body of Huns under Uldin (father of Attila), and of Visigoths under Sarus, he so harassed the invaders that they were forced to give him battle. They were soon completely routed; Radagaisus was put to death, and his followers sold as slaves. Stilicho now returned to his own ambitious schemes, established enmity between Rome and Byzantium by seizing on eastern Illyricum and inducing Alaric to transfer his allegiance to Honorius. But Honorius, who had been prejudiced against Stilicho by one of his officers, Olympius, refused to take eastern Illyricum from the Byzantine empire; and subsequently by an artful bargain he so influenced the soldiers of the army of Gaul that they rose *en masse* against the partisans of Stilicho. Stilicho himself was at Bologna; and on the news of the revolt, his most zealous friends urged immediate action against Olympius and the Pavian rebels; but for the first time in his life vacillation seized the soldier. He was soon forced to flee to Ravenna, where he was murdered, 23d August 408. Thus perished the last of the series of distinguished aliens, who, as emperors, warriors, or politicians, had propped up the Roman empire for 150 years, with a stern and resolute zeal equal to that of the early Romans themselves. Three months after his death Alaric and his Visigoths were at the gates of Rome.

Still is an apparatus for Distillation (q.v.). It consists essentially of a vessel in which the liquid to be distilled is placed, the vapour being conducted by means of a *head* or *neck* to the condenser or worm, where it is cooled by water or other means, and again forms liquid. The still itself varies greatly according to the purpose for which it is used. It is made of copper, iron, earthenware, or glass, and is heated by naked flame or steam-heated. The steam may either be applied on the outside by means of a *jacket* or inside by the use of a *coil*. A *vacuum still* is one in which a partial vacuum is constantly maintained by means of an air-pump, distillation under such circumstances being more rapid and at a lower temperature. See also RETORT.

Stillborn. See OBSTETRICS, ABORTION, and FETUS.

Stillfieldium. See EAVESDROP, SERVITUDE.

Stillingfleet, EDWARD, a learned English divine, was born at Cranborne in Dorsetshire on 17th April 1635. There and at Ringwood he received his early education, at thirteen entered St John's College, Cambridge, where he took his degree in 1652, and the year after obtained a fellowship. For some years after leaving college he was occupied as a private family tutor; and in 1657 he was presented to the rectory of Sutton in Bedfordshire. In 1659 appeared his *Trenicium, or the Divine Right of Particular Forms of Church Government examined*, a noble catholic-spirited attempt to find a mean as a basis of union for the divided church. His views savoured somewhat more of latitudinarianism than could be pleasant to the High Church party, and indeed Stillingfleet himself afterwards thought fit to modify them. His *Origines Sacre, or the Truth and Divine*

Authority of the Scriptures (1662), a creditable contribution to the Apologetics of the day, was followed by his *Rational Account of the Grounds of the Protestant Religion* (1664), a defence of the Church of England from the charge of schism in its separation from that of Rome. These works were received with great favour, and quickly led to rich preferment. In 1663 the Earl of Southampton promoted him to the rectory of St Andrews, Holborn; he was also appointed preacher at the Rolls Chapel, and shortly after lecturer at the Temple, and Chaplain in Ordinary to Charles II. In 1670 he became Canon Residentiary, in 1678 Dean, of St Paul's. In the Court of Ecclesiastical Commission instituted by James II. Stillingfleet declined to act; and after the Revolution of 1688 he was raised to the bishopric of Worcester. He died at Westminster on 27th March 1699, and was buried in Worcester Cathedral. So handsome in person as to have been popularly called 'the beauty of holiness,' he had, Burnet tells us, a reserved and hanghty temper. But he was courteous and temperate in debate, and he had the rare merit for a theologian of being capable of appreciating the courtesy of an opponent. Thus, in the controversy that grew out of his *Mischiefs of Separation* (1680), he candidly confessed himself overcome by the answer of John Howe, who, he said, wrote 'more like a gentleman than a divine, without any mixture of rancour.' Other works were his *Origines Britannicæ, or Antiquities of the British Churches* (1685), and a defence of the doctrine of the Trinity (1697). His collected works, with Life by Dr Richard Bentley, were published in 1710 (6 vols. folio); a supplementary volume of Miscellanies, edited by his son, in 1735. See Tulloch's *Rational Theology in the Seventeenth Century* (vol. ii. 1872). - His grandson, BENJAMIN STILLINGFLEET (1702-1771), amongst other things a dilettante and botanist, wrote *Thoughts concerning Happiness* (under the pseudonym Irenæus Kriantzoivius, 1738), *Essay on Conversation, Miscellaneous Tracts relating to Natural History, Husbandry, and Physick* (a translation from Linnaeus), with an original preface on *Grosses* (1759), *Principles and Power of Harmony* (1771), and several dramas; he left in preparation a *General History of Husbandry*. His Life and Select Works were published by W. Coxe in 1811. See BLUE-STOCKING.

Stillingia. See EUPHORBACEÆ, TALLOW-TREE.

Stillwater, capital of Washington county, Minnesota, on the navigable St Croix River (which here expands into a narrow lake), 18 miles by rail NE of St Paul. It has a large lumber trade, and contains sawmills, a foundry, flour mills, and a state prison. Pop. 8000.

Stilt (*Himantopus*), a widely distributed genus of wading-birds belonging to the Snipe family (Scolopacidae). They have long slender bills and very long wings and legs, the length of the legs being almost equal to that of the body. The Black-winged Stilt (*H. candidus*) has been occasionally met with in Britain, but is only a rare summer visitor, though it breeds in Holland and southern Europe. The prevailing colours of plumage among the stilts are black and white, but a pure black species inhabits New Zealand.

Stilton, a village in the north of Huntingdonshire, 6 miles SW. of Peterborough. It gives name to the well-known cheese, manufactured elsewhere, but once much sold at Stilton.

Stilts, poles with steps or supports at a sufficient distance from the lower end to allow a man standing on the steps to walk clear of the ground and with longer strides. Useful in all marshy lands, they were in old days specially serviceable in the

French Landes (q.v.), where the shepherds practically spent the whole day on stilts. Elsewhere they serve for crossing streams (as the upper Tweed and Clyde), for a (somewhat dangerous) pastime for boys, and for displays of acrobatic skill. At Namur one of the diversions of the carnival was a tournament between bodies of men mounted on stilts.

Stimulants are agents which increase the activity of the vital functions generally, or of one system or organ. Their action is usually understood as being transient and rapid, but is not necessarily so. They are most commonly employed to act on the nervous and circulatory systems, but hepatic, renal, and gastric stimulants are also common terms in medicine. Popularly only those which act on the nervous and circulatory systems are well known, and include alcohol in the form of wines and spirits, sal-volatile, smelling-salts and other preparations of ammonia, besides ether, camphor, various preparations of lavender, peppermint and other essential oils, ginger, &c. Cold and electricity also act as stimulants. They are useful in fainting, nervousness, shock, hysteria, and similar conditions. See the articles on ALCOHOL, ELECTRICITY (MEDICAL), &c.

Sting-fish. See WEEVER.

Stinging-animals. In many different ways animals have the power of stinging. To begin with the minutest, the trichocysts of the slipper-animalcule (Paramecium) are often regarded as weapons, though they are more probably mooring-threads. Most Cœlenterates, such as jelly-fish and Portuguese-man-of-war, have Stinging-cells (q.v.). The surprising occurrence of stinging cells in some Nudibranchs has been proved to be due to a diet of Cœlenterates. The stings of ants, bees, and wasps and some other Hymenoptera are abdominal structures, probably homologous with appendages, and they are associated with a poison-secreting gland. The poison of spiders is lodged in the chelicere or first pair of oral appendages. The sting of the scorpion consists of a double poison-gland lodged in the sharply pointed segment or 'telson' which lies behind the anus at the end of the tail. The sting-rays (*Trygon*) have no special poison-glands, but it is probable that the inflammation which follows their wounds is due either to the mucus alone or to that plus micro-organisms introduced therewith. In the case of the weavers, both the British species (*Trachinus draco* and *T. vipera*) have special poison-glands in connection with spines, and their wounds are only too well known to fishermen. Finally, the stinging powers of the venomous snakes are due to the modification of one of the salivary glands on each side as a poison-gland and to the adaptation of the teeth as fangs. In the poisonous Mexican lizard *Heloderma* an approach to a similar specialisation occurs. See also POISON.

Stinging-cells, or CNIDOBLASTS, are characteristic of all Cœlentera except Ctenophores. To them the jelly-fish, Portuguese-man-of-war, sea-anemones, and the like owe their power of stinging. They serve to benumb or kill or grapple the small animals on which most of the Cœlenterates feed. Each stinging-cell contains a long coiled lasso or nematocyst bathed in poisonous fluid; at the base of the cavity in which the lasso lies there is a little living matter and a nucleus; projecting from the surface there is often a small trigger-like peak. When the cell is stimulated, in some cases at least by nervous impulse from adjacent nerve-cells, the lasso, which is many times the length of the cell, is rapidly everted. After this has taken place the cell dies. In many cases the cnidoblasts are grouped in little 'batteries.' See CœLENTERATA, HYDRA.

Stinging Plants. See COWHAGE, LOASACEÆ, NETTLE, NETTLE-TREE, URTICACEÆ.

Sting-ray (*Trygon*), a genus of cartilaginous fishes, of the Ray (q.v.) order and family Trygonidae. The long tail bears dorsally a long

Sting-ray (*Trygon pastinaca*). *T. sepien* and *T. urinalis*, attain a large size. Only one species occurs in the British seas, *T. pastinaca*, popularly known as the Fire-lance. The spine of the sting-ray is used by the savages of the South Sea Islands as a point to their spears.

Stinkpot. See ASPHYXIANTS.

Stinkstone, or SWINESTONE, a kind of marble or limestone remarkable for the fetid rancid odour which it emits when rubbed. It contains a little sulphur.

Stink-trap. See SEWERAGE.

Stink-wood (*Ocotea bullata*), a very valuable South African tree of the family Lamaceæ, remarkable for the strong disagreeable smell of its wood, which, however, is hard, very durable, takes an excellent polish, and resembles walnut. It is used for wagons, furniture, panelling, &c.

Stint. See SANDPIPER.

Stipa. See FEATHER-GRASS.

Stipend is the provision made for the support of the parochial ministers of the Church of Scotland. The Church of Scotland has from its inception been organised on a territorial basis, and its endowments, so far as coming from public sources, are almost entirely appropriated to the individual parishes. In the old parishes the stipend was paid out of the tithes or teinds of the parish (see TEINDS), and the ministers of these parishes had a right to have competent stipends awarded to them by the Court of Teinds out of the teinds of their respective parishes in so far as these were adequate. The teinds of *quoad sacra* parishes are included in those of the parishes out of which they were carved, and thus the areas of the *quoad sacra* parishes contribute from their teinds to the stipends of the original, not of the *quoad sacra*, parishes. Stipends were, as a general rule, awarded out of teinds, not in money, but in grain measured by chalders. The money value of the stipend therefore varied in amount from year to year owing to the variations of the grain prices struck annually in each county, which rose and fell with the price of grain (see FIARS). When the existing stipend of a minister was deemed insufficient, the Court of Teinds, provided there remained any surplus or free teind in the parish, might award out of it such augmentation of stipend as was considered suitable. But no augmentation could be applied

for within twenty years after the last augmentation.

The Report, dated 4th April 1923, of the Departmental Commission appointed by the Secretary for Scotland to inquire into the tenure and endowment of the Church of Scotland contains a statement of the sources out of which stipends—so far as these (a) accrued from public sources, or (b) were drawn from voluntary sources but administered under acts of parliament—were payable at the date of the report. (1) There were 880 old parishes in which the stipends were payable out of teinds. These included a certain number of parishes—known as Exchequer livings—the stipends of which were augmented by grants, payable out of the Consolidated Fund, under the Acts 50 Geo. III. chap. 84, and 5 Geo. IV. chap. 72, which were passed for the purpose of supplementing small stipends. By the later of these acts a parish minister, who had neither manse nor glebe, and whose income was less than £200 per annum, was entitled to an allowance making up his stipend to a sum not exceeding that amount. The annual sum provided under these acts was applied at the sight of the Court of Teinds on reports by the teind clerk. The sum of £12,000 is chargeable annually on the Consolidated Fund in respect of these grants to Exchequer livings. (2) There were 42 parliamentary charges, provided under the Act 5 Geo. IV. chap. 90, in each of which a stipend of £120 is payable out of the Consolidated Fund. (3) There were 46 town churches, the stipends of whose ministers were payable by burghs out of special funds held by burghs. (4) There were about 500 *quoad sacra* parishes whose endowments were derived from voluntary sources, but were administered under decrees of the Court of Teinds in accordance with the New Parishes (Scotland) Act, 1844 (7 and 8 Vict. chap. 44).

The Church of Scotland (Property and Endowments) Act, 1925 (15 and 16 Geo. V. chap. 33), which came into force on 28th May 1925, has introduced important changes affecting stipends. Under the act every stipend which in any way or to any extent depended upon fluctuations in the price of grain—referred to in the act as 'victual stipend'—is to be converted, at the standard of value defined in the act, into a stipend payable only in money. The method provided in the general case for effecting this conversion is that the standard value in money of victual stipend for each county shall be determined by adding to the former county average value of the different kinds of victual in which such stipends are localised an increase of 5 per cent. per annum of that average value—the former county average value of any kind of victual being deemed for this purpose to be the average value of that kind of victual for that county for the fifty years 1873 to 1922. It is, however, enacted that, in the application of this provision to a particular parish, regard is to be had to special circumstances affecting the calculation of value of stipend in that parish. The value in money of any victual stipend, as the same may be determined under these statutory provisions, along with the value of any money stipend, is the 'standard value' of that stipend. The substitution of the new permanent or standard value of victual stipend for the former fluctuating value of such stipend is termed the 'standardisation' of the stipend. It is enacted that the date of standardisation of a stipend is to be the term of Martinmas which shall first occur not less than six months after the date when the benefice becomes actually vacant, or is deemed to become vacant (a) by 'election,' that is, by the minister, who at the date of the act is entitled to a victual stipend, electing that the stipend shall be standardised, and intimating his election

in writing to the heritors, to the clerk of the presbytery, and to the General Trustees of the Church, or (b) by 'notification,' that is, by the General Trustees intimating in writing to the minister of any parish, who is entitled to victual stipend, to the clerk of the presbytery, and to the heritors that the victual stipend is to be standardised. The standardised stipend, on and from the date of standardisation, vests *de die in diem* in the minister entitled thereto—any interest which, under the previous law and practice, had vested in the minister at that date or in the widow or other representatives of a deceased minister being safeguarded. The act provides that the standardised stipend is, as from the date of standardisation, payable by the heritors to the General Trustees half-yearly at Whitsunday and Martinmas; but this provision ceases to operate so soon as the amount of the standardised stipend as shown by the Teind Roll—a roll prepared by the clerk of teinds—is constituted a real burden on the lands of the heritors, or has been redeemed or extinguished. The former law relating to augmentations of stipend ceased, as from the date of the act, to have effect. Under the act, however, the minister or General Trustees may—subject to certain time conditions based on the previous law and practice—apply to the Lord Ordinary to find whether there are surplus teinds available for an augmentation; but no such application can be made after the expiry of eleven years from the passing of the act. If, on such application, it be found that there are surplus teinds available, the stipend is to be augmented according to a scale set out in sect. 10 (3) of the act. An augmentation under this section of the act comes in place of all future rights of augmentation, and is final. Neither the widow nor any other representative of any minister admitted after the passing of the act to any benefice is to be entitled to ann (see ANNATIES). The annual payments out of the Consolidated Fund to or on behalf of the Church are thenceforth to be paid by the Treasury to the General Trustees, with certain powers for redemption. These annual payments include—in addition to the sum of £12,000 in respect of the grants to Exchequer livings (*supra*) and the sum of £5040 on account of stipends in parliamentary charges (*supra*)—a sum of £2000 for itinerant preachers and a sum of £1100 towards the expenses of the General Assembly.

Stipendiaries. See MERGENTIARIES.

Stipendiary Magistrates. See BOROUGH.

Stirling, the county town of Stirlingshire, stands on the south bank of the winding Forth, 36 miles NW. of Edinburgh and 29 NNE. of Glasgow. Like Edinburgh, to which in its main features it bears a striking resemblance, it no doubt owes its origin to the strong natural fortress of its Castle Hill, which rises gradually from the east to a height of 420 feet above the sea or 340 feet above the plain, and fronts the west with a steep precipitous wall of basaltic rock. The Castle, which commands magnificent views of the Grampians, the Ochils, and the 'Links of Forth,' dates from immemorial antiquity, though few, if any, of the existing buildings are earlier than the days of the Stewart sovereigns, who often kept court here. These include the Douglas room (where the Earl of Douglas was stabbed by James II., 1452), James III.'s parliament-hall (now a barrack-room), James V.'s palace, and James VI.'s chapel. Stirling has many other objects of interest, as Argyll's lodging (1630, since 1799 a military hospital); ruined Mar's Work (c. 1570); the church of the Holy Cross, or Holy Rood, the parish church of Stirling (in 1656 divided into two); the statue of Bruce (1877); the new cemetery, with statues of

Reformers and Covenanters; Cowane's Hospital or the Guildhall (1637); the King's Knot and King's Park; the Mote or Heading Hill; the old four-arch bridge (c. 1400—the 'key of the Highlands'); Robert Stevenson's new bridge (1832); and the Smith Institute (1874), with picture-gallery and museum, where now is preserved the 'Stirling Jug' (1497), the standard of the old Scots pint. Other modern edifices are the County Buildings (1875), the public hall (1883), the High School (1855-89), and the Municipal Buildings (1918). In the neighbourhood are Bannockburn (q.v.); the ruins of Cambuskenneth Abbey, founded by David I. in 1147 for Augustinian monks, and the burial-place of James III.; and the Abbey Craig (362 feet), crowned by the Wallace Monument (1861-69), a tower 202 feet high. Stirling has manufactures of carpets, agricultural implements, &c. A royal burgh as early as 1119, it unites with Falkirk and Grangemouth (by the act of 1918) to return one member to parliament. Pop. (1851) 12,837; (1881) 16,013; (1921) 21,345. Stirling (formerly *Strgyrlene* or *Estrivelin*, and also *Snoedown*) has a wealth of historic memories—the death of Alexander I. and William the Lion; Wallace's victory of Stirling Bridge (1297); the great siege of the castle by Edward I. (1304); the birth of James III.; the coronation of Queen Mary; the baptism and coronation of James VI.; the slaughter of the Regent Lennox (1571); the birth of Prince Henry (1594); the capture of the castle by Monk (1651); and its unsuccessful siege by the Jacobites (1746).

Stirling, JAMES HUTCHISON, the most eminent of later Scottish philosophers, was born at Glasgow, 22d June 1820, took the course in both arts and medicine at Glasgow University, and practised a short time as a physician in South Wales. He next went to Germany, and gave himself devotedly for some years to the study of philosophy. The publication of his masterly and epoch-making work, *The Secret of Hegel: being the Hegelian System in Origin, Principle, Form, and Matter* (1865; 2d ed. 1898), opened up an unknown world to readers, and gave a powerful impulse to the study of philosophy generally. This work, as full of individuality as learning, was followed in 1881 by a *Complete Text-book to Kant*, comprising a translation and reproduction of the *Critique of Pure Reason*, with a commentary and biographical sketch. These two works stand together in the most intimate relation, for, according to Stirling, from Kant's antecedent system Hegel's philosophy itself was but 'a development into full and final shape.' At the same time Dr Stirling brought Kantian speculation into line with English thought by demonstrating that the central problem of the critical philosophy was a question that had been already propounded, if not answered, by Hume. Stirling received the degree of LL.D. from Edinburgh in 1867, and was elected a foreign member of the Philosophical Society of Berlin in 1871. He delivered the first course of Gifford Lectures at Edinburgh, and these were published in 1890, the whole forming a vigorous if somewhat discursive work, in which natural theology is considered in its relation to the history of philosophy, and investigated mainly from the point of view of reason and the principles involved in the Theistic inference. Of the famous three proofs—the Teleological, the Cosmological, and the Ontological—he deals mainly with the first. 'Begin with which we may, and let them be separated from each other as they may be in time, the three, after all, do constitute together but the three undulations of a single wave, which wave is but a natural rise and ascent to God, on the part of man's own thought, with man's own experience and consciousness as

the object before him.' Other works of Dr Stirling's are *Sir William Hamilton: being the Philosophy of Perception* (1865), an assault on Hamilton's doctrine of perception more serious still than Mill's; an excellent translation of Schwegler's *History of Philosophy* (1867); *Servold, Tennison, and Macaulay, &c.* (1868); *As Regards Protoplasm* (1869; complete ed. 1872), an answer to Huxley's *Essay on the Physical Basis of Life: Lectures on the Philosophy of Law* (1873), together with an incisive attack on Whewell and Robertson Smith for their statements anent Hegel's relations to Newton and the calculus; *Burns in Drama* (1878); *Darwinianism: Workmen and Work* (a criticism of the three Darwins, 1894); besides lectures on Materialism, Philosophy in the Poets, &c., and the article on Kant in *Chambers's Encyclopedia*. He died 19th March 1909. See Life by his daughter (1912).

Stirling. WILLIAM ALEXANDER, EARL OF, minor dramatic poet, a contemporary and dear friend of Drummond of Hawthornden, was born at Menstrie House near Allon, most probably about 1567—hardly so late as 1580, the usual date formerly given. He studied at Glasgow and Leyden, travelled through France, Spain, and Italy with Archibald, seventh earl of Argyll, and began his career as a poet by publishing at Edinburgh, in 1603, his tragedy of *Darius*, quickly followed by *Aurora*, a collection of sonnets (Lond. 1604), *Cræsus* (together with *Darius*, 1604), the *Alexandrian Tragedy* (1605), and *Julius Cæsar* (1607). These were collected as *The Monarchicke Tragedies* in 1607. He was knighted by 1609; in July 1613 was attached to the household of Prince Charles, as before he had been to Prince Henry's; in 1614 was made Master of Requests for Scotland, publishing the same year the first part of his great poem of *Doomeday* (second part, 1637), which extends to 11,000 verses, and which himself even allows in the dedication to be of 'too melancholic a nature for young minds.' He received in 1621 the grant of 'Nova Scotia'—a vast tract of Canada and the northern part of the modern United States—his charter being renewed in 1625; and in 1631 he received the patent of sole printer for thirty-one years of King James's version of the Psalms, a work to which he had contributed greatly, but which proved an utter failure. In 1626 he was made Secretary of State for Scotland, which office he held till his death, despite his unpopularity. Baillie writes of him as 'extremely hated of all the country, for his alleged bribery, urging of his psalms, and the books for them.' In 1627 he was made Keeper of the Signet, a Commissioner of Exchequer in 1628, and one of the Extraordinary Judges of the Court of Session in 1631. The French pushed their conquests in America, and Alexander's grant of lands thereby became useless. He was promised £10,000 compensation, but the money was never paid. In 1630 he was created Lord Alexander of Tullibody and Viscount Stirling. In 1633, at the crowning of Charles in Holyrood, he was made Earl of Stirling and Viscount Canada, in 1639 also Earl of Dovon, but he sank into insolvency, and died in London, 12th September 1640. His body was embalmed and buried at Stirling a few months later. The title died out with the fifth earl in 1739. His tragedies are not dramatic, but their quatrains are gracefully written, albeit the quantities are monstrous—witness Ixion, Nicmor, Orion, and Enmènes. The *Parænesis* to Prince Henry is perhaps his finest work; the songs, sonnets, elegies, and madrigals forming the *Aurora* are sadly marred by conceits, yet show rich fancy and ingenuity, though scarce even a Scotsman can claim for them that they sparkle still the right Promethean

fire. These amatory poems the author did not include in his collected *Recreations with the Muses* (folio, 1637).

His works were edited, with elaborate essays, by Kastner and Charlton (vol. i. 1921). See also the Rev. Charles Rogers, *Memorials of the Earl of Stirling and the House of Alexander* (2 vols. 1877) and his edition of the *Earl of Stirling's Register of Royal Letters* (1615-35).

Stirling-Maxwell. See MAXWELL.

Stirlingshire, a midland county of Scotland, forming part of the border-land between Highlands and Lowlands, is bounded by Perth, Clackmannau, Linlithgow, Lanark, and Dumfries shires. With a maximum length and breadth of 46 and 22 miles, it has an area of 451 sq. m., or 288,842 acres, of which 3000 are foreshore and 8000 water. The Forth traces much of the northern and all the north-eastern boundary; on the western lies Loch Lomond; and other lakes and streams belonging partly or wholly to Stirlingshire are Lochs Katrine and Arkit, and the Avon, Carron, Bannock, Endrick, and Blane. Ben Lomond, in the north-west, attains 3192 feet; and lesser elevations are the Gargunnoch Hills (1591 feet), Kilsyth Hills (1393), Campsie Fells (1894), and Embury Hills (1676). A considerable part of Stirlingshire is occupied by the rich carse of Stirling and Falkirk, once covered with unproductive peat-moss. About 40 per cent. of the whole area of the county is in cultivation. Coal and ironstone are largely mined; and there are the great ironworks of Carron and Falkirk, besides manufactures of woollens, cotton, chemicals, &c. The chief towns are Stirling, Falkirk, Kilsyth, Denny, and Grangemouth. With Clackmannanshire, the county returns two members to parliament. Pop. (1801) 50,825; (1841) 82,057; (1881) 112,443; (1921) 161,726. In Stirlingshire were fought the battles of Stirling Bridge, 1297; Falkirk, 1298; Bannockburn, 1314; Sauchieburn, 1488; Kilsyth, 1645; and Falkirk, 1746. See Nimmo's *History of Stirlingshire* (3d ed. 1880).

Stürner, MAX, was the pseudonym by which Kaspar Schmidt (1806-56) became known as a representative of 'individualist anarchism.' A predecessor of Bakunin, he taught that night is right, morality the weapon of tyrants and the fetter of fools, and egoism the standard. Born in Bayreuth, he studied at Berlin, and taught in a girls' school there. *The Ego and his Own* was translated in 1912.

Stitch in the side is the popular and expressive name applied to sharp pains felt in various parts of the side. It seems that these may be due to various causes; thus, they may be associated with pleurisy where there is no effusion, or with a stretching of the not uncommon adhesions between two pleural surfaces, or simply with local spasms of the respiratory muscles, as when a person takes violent exercise after a full meal, or perhaps even with a slight twisting of part of the intestine. When the stitch is but slight it is often removed by stooping, hence the popular remedy is to make a cross upon the foot.

Stitchwort. See CHICKWEED.

Stiver (Dutch *stuiver*), a coin of Holland, equivalent to a penny sterling, being the $\frac{1}{20}$ th of a guilder or guilder. See FLORIN.

Stoat. See ERMINE.

Stobæus, JOANNES, a native of Stobi in Macedonia, who compiled for his son Septimius, about 500 A.D., an anthology in four books from as many as 500 Greek poets and prose-writers. It has preserved for us fragments from many works now lost, and is especially rich in quotations from

the Greek dramatists. Originally forming one whole, the work in course of time became divided into two divisions, each of two books: *Eclogæ Physicæ et Ethicæ* (ed. Gaisford, 1850; Meineke, 1860-64), and *Anthologion or Florilegium* (Wachsmuth, 1884), containing the precepts on political and ethical subjects (ed. Gaisford, 1822-25; Meineke, 1856-57).

Stock, or STOCK GILLYFLOWER (*Matthiola*), a genus of Crucifere, with cylindrical or compressed pods, and a stigma consisting of two upright appressed plates, the outer side of which often rises into a knob or horn. The species are herbaceous, annual or perennial, or half-shrubby, natives of the countries around the Mediterranean Sea, most of them thickly clothed with white or grayish stellate hairs; the flowers in racemes, and generally beautiful and fragrant. Some of the species have long been much cultivated, and many fine varieties have been produced by cultivation. *M. incana*, a very rare and even doubtful native of England, is probably the parent of the greater number of the cultivated kinds. The sandy shores of Wales and of Cornwall produce a species, *M. sinuata*, the large purple flowers of which are fragrant only at night—a characteristic also of several other species. Stocks are always raised by gardeners from seed, which even the double kinds often produce, a multiplication of the petals having taken place without loss of the parts of fructification. Of the seedlings, however, some produce double and others single flowers, so that only some gratify the cultivator. The hoary-leaved stocks are generally treated as biennials, although, in reality, they may almost be reckoned perennial; and it is not desirable that they should flower in the first year, as the plants become stronger when they remain without flowering till the second year, and produce richer racemes of flowers. The smooth-leaved stocks are treated as annuals. The beautiful little annual called Virginian Stock does not belong to this genus, although it is of the same family. Its habit is indeed very different. It is *Malcolmia maritima*, and, notwithstanding its popular name, is a native of the shores of the Mediterranean. It has become one of the most favourite British flowers, almost rivaling mignonette, and is all the more esteemed because it grows well in garden-plots exposed to the smoke of towns.

Stockbridge, a little market-town of Hampshire, on the Anton or Test, 8 miles W. by S. of Andover. Till 1832 it returned two members to parliament: Steele at one time was its representative. It has a well known racecourse and training stables.

Stock-exchange. The London Stock-exchange as a corporate body only dates from the commencement of the 19th century. Prior to the establishment of the Stock-exchange in 1801 transactions in the funds were conducted in a very slipshod manner by groups of individuals, who till about 1698 used the old Royal Exchange in London as a meeting-place, and then for a century made one of the network of alleys in Cornhill their headquarters, congregating in Change Alley both in the open air and in the Jonathan and Garraway coffee-houses. Dealings in Government funds were also conducted in the Rotunda Room in the Bank of England. The founders of the Stock-exchange acquired premises in Capel Court, facing the eastern side of the Bank of England. The original capital subscribed for providing the accommodation was 400 shares of £50 paid. Nothing further was required for upwards of half a century in the way of capital. Subsequently considerable expenditure, especially since 1870, raised the total share capital

to £500,000 in 20,000 shares, £25 paid up per share, and there remain unredeemed £307,900 in 3 per cent. debentures of £450,000 originally created in 1899-1900. In the early days of stock-dealing transactions were almost entirely in the different forms of British Government funds, lottery bonds, and floating debt; but Change Alley, just as Capel Court in the 19th century, had wild fits of gambling in company schemes, of which the most memorable, the South Sea Scheme (q.v.), culminated in 1720.

At the time the first stone of the Stock-exchange building was laid in 1801 the total national debt of Great Britain was some £550,000,000, and the Stock-exchange list, published bi-weekly, comprised only six securities, chiefly British Government stocks. Foreign governments first came to the English market as borrowers in 1816 to 1825, and the bonds of various European and American states, Russian, Portuguese, Neapolitan, Danish, Greek, Colombian, Mexican, Buenos Aires, Chilean, Peruvian, &c., came to be dealt in. There were also transactions in a few canal, insurance, and industrial companies, including shares of the Gas-light and Coke Company. Numerous banking corporations were established immediately after 1833. The introduction of railways in the United Kingdom and on the Continent in the period from 1840 to 1846 added largely to the business of the Stock-exchange. The gold discoveries of 1848-50 brought about the formation of a crowd of British, colonial, and foreign mining schemes. The introduction of joint-stock companies after the Act of 1862, the growth of foreign government debts, and the introduction of Indian and colonial borrowings, municipal loans, gas, water, shipping, telegraph, tramway, rubber, oil, manufacturing, &c., undertakings, as well as a great number of colonial and foreign railroad, &c., securities, have added enormously to the amount of securities dealt in. In 1911 the official daily Stock-exchange 'List' comprised some 5200 securities. At the end of March 1924 the 'official' list of quoted and further unquoted securities aggregated probably between 12,000 and 13,000 different items. The official list now comprises twenty large pages of names of securities.

Outside London there are the provincial establishments—Manchester, Liverpool, Leeds, Birmingham, Bristol, Glasgow, Edinburgh, Dublin, Belfast; and other important centres of the United Kingdom have their stock-exchanges administered by committees, all having rules and regulations much on the same lines as those of the great London establishment. On the Continent every important city has its stock-exchange or *Bourse*. New York, Philadelphia, Baltimore, Chicago, San Francisco, and other important American cities have their stock-exchanges; and there are *Bolses* in South American cities. Transactions in public funds and securities of joint stock companies are also conducted in leading Indian and colonial cities.

The control of affairs of the London Stock-exchange is vested in two separate bodies:

- I. The trustees and managers—who must *ipso facto* be members—who represent the proprietors of the building, and are elected by the shareholders.
- II. The committee for general purposes—thirty in number are elected annually, in March, by the members.

The second body is responsible for the framing and observance of the rules, the maintenance of discipline, the granting of quotations, dates of settlements, investigation of disputes, whether between members themselves or members and the public, the admission of members and clerks, &c. The committee has powers to censure, suspend, or

expel any members for infraction of the rules or dishonourable conduct.

There have in times past been disputes between the two governing bodies, but a new scheme provided that each new member must also be a shareholder. Such regulation will automatically in time blend the two administrations into one. The proprietors, at 1st January 1876, numbered 268; at 24th March 1926 there were 2523 proprietors.

At the time when the London Stock-exchange was opened in 1802 there were 551 members and 99 clerks. In 1904 the roll of members included upwards of 3800 names, and there was an army of house clerks. In 1926 the members numbered 3858, and there were 1884 non-member clerks—authorised to deal for their employers and unauthorised, all with right of entry to the exchange buildings.

Members have to declare whether they act as brokers or jobbers, and subsequently may notify the committee of intention to change over from the one to the other.

The broker transacts business as between members of the Stock-exchange and the public, obtaining his commission from the clients who employ him. He deals in all securities, at rates of commission fixed by the committee, and published in the Rules and Regulations (Appendix xxxix. of the Rules).

The jobber or dealer confines his attention to some special group of securities and generally offers to buy at one price or sell at a higher price. The margin between the buying and selling prices he may quote to any broker or fellow jobber varies according to the nature of the security, the extent of competition, the state of the market, &c.

Official schedules of the names of firms and individuals who are brokers are obtainable by the public free of charge from the Stock-exchange secretary, and one is posted up for public information in the Bank of England. A list is now embodied in the *Stock Exchange Official Intelligence*. No such schedule is issued to the public as to the names of 'jobbers' or 'dealers,' but information can be obtained, as each year the committee issues a full list of the firms and individuals of the Stock-exchange, setting out the date of admission, addresses of office and private bankers, telephone numbers, &c.

In 1821 each applicant for membership was required to provide two existing members as sureties for the sum of £250 each, who were held liable in their suretyship for two years. Various alterations have since been made.

At the present time an individual seeking membership, if he has not for a period of four years served as clerk in the Stock-exchange, is required to obtain nomination of a deceased or retired member, has to obtain the suretyship of three members responsible for £500 each for four years, has to purchase three Stock-exchange shares and pay an entrance fee of 600 guineas, and the annual subscription current at time of his application. At present such subscription is 100 guineas. Such annual payments and the annual subscriptions have in course of years gradually increased.

For any applicant who has served as an authorised or unauthorised clerk to a member or firm for a period of four years the conditions are not so onerous as for an inexperienced applicant. The trained man of four years' experience has to acquire a nomination and one Stock-exchange share. He has to find two sureties for £300 each for four years. His entrance fee is 300 guineas, and the present annual subscription is 50 guineas. Each year the committee grants a certain number of free nominations to clerks who have been in the 'House' for four years, and would-be members of this class can enter their names on a waiting list. Their entrance fee is also 300 guineas.

Registered and Bearer Securities.—Stock-exchange securities are of two characters, inscribed or registered, and to bearer. In home government funds and several colonial and municipal 'inscribed' issues the names of stockholders are registered (*inscribed*) in books kept at the Bank of England, or other banking agents of the government or corporation. When such stock is sold the vendor or his attorney must attend the bank and sign the transfer in the books. Where stock in a railroad or other company that registers the name of the stockholder is sold by the registered proprietor a deed of transfer, subject to stamp-duty, has to be executed, and this deed, with the relative stock or share certificate, is passed to the purchaser, who directly or through his agent, lodges them with the company for registration into his own name. Securities to bearer are those the title to which passes by mere delivery, and the interest or dividends are paid periodically by means of coupons.

Settlements.—The great bulk of stock-exchange transactions in Great Britain are purchases or sales or what is termed the *settlement*, which is monthly. Important exceptions, however, are all descriptions of British and colonial securities, dealings in which have, since the reopening of the Stock-exchange after the Great War, been for cash only. In dealing in registered securities it is necessary for the purchaser or seller to furnish the broker entrusted with the business with full particulars. A purchaser should give his full name, address, and occupation. A seller is required to forward to the broker the certificate of title. Where the transaction is in securities to bearer the vendor simply has to hand the securities to his broker, and the transaction is in all respects similar to the exchange of a bank-note for cash.

In cases of new issues of companies, dealings are only permitted after sanction has been granted by the committee.

Although the London Stock-exchange is not, as generally is the case on the Continent, in any way controlled by the Government and has not a monopoly, till recent years it practically secured the whole of the *bona fide* business of buying and selling British Government securities. But since the Great War period creation of vast Government loans and great increase in all manner of new capital issues, the banking companies have in many cases induced their clients to give buying and selling orders to their managers throughout the country, and though the orders are effected through the Stock-exchange, the banks, also most lawyers, who give orders for clients, receive half the stock-brokers' commission charge.

Members of the Stock-exchange voluntarily place themselves under the most stringent rules and regulations, and the slightest irregularity is visited with prompt pains and penalties. There is no appeal from decisions that may be made by the committee, and no legal action may be instituted by one member against another except with the consent of the committee.

Immediately prior to the war declaration, August 1914, the hitherto unprecedented step was taken—31st July—of compulsory closing of the Stock-exchange at the request of the Government, and projects for the minimising of effect on the world of finance were considered. An outcome of these deliberations was the fixing of minimum prices below which transactions were not permitted and the granting of a moratorium—the duration eventually decided as till a year after conclusion of peace—in respect of all transactions which had not been consummated at the time.

In January 1915 the Stock-exchange was, with the consent of Government, reopened, but the conditions of dealing which had been mutually agreed

upon by the Treasury officials and the Stock-exchange Committee were so restricted that free markets were non-existent and dealings could be effected for cash only. Obviously every precaution had to be taken to preclude the chance of enemy-held securities being marketed in the United Kingdom *via* neutral countries, and all transactions had to be accompanied by a declaration of British ownership.

With the termination of the war restrictions were gradually removed, and all bargains unsettled at the outbreak of war were finally adjusted in August 1922. Shortly after that date all war-time restrictions and declarations were removed. One exception of importance was that dealings in all British, Indian, and Colonial Government securities could be effected for cash only.

Prior to the war, by telegraph and telephone, an enormous amount of *arbitrage* business had been transacted between international exchanges, especially between New York, Paris, and London. Closely observant dealers, finding a security could be bought cheaper in New York than in London, purchased in New York and sold the stock in London. Such arbitrage business was conducted between the exchanges of all the world. The outbreak of war put a stop to all arbitrage London dealings with the Continent and America, and the aftermath of upheaval and demoralisation of foreign currencies has reduced arbitrage business to a minimum.

Bulls, Bears, Contango, Backwardation, Corners, Options—A very large proportion of the business done in the stock-markets prior to the war was speculation in *time bargains*. A purchaser who imagines that some special security is likely to rise in price buys for the settlement, in the hope of being able to sell at a profit before the date for payment falls due. If a change in price the way he expects is delayed, he renews the transaction from settlement to settlement. It may be the case that a fall in price is expected, and an operator sells in the hope of being able to buy back at a lower price. The purchaser for a higher quotation is in stock-exchange parlance called a *bull*. The seller who anticipates a fall in prices is termed a *bear*. If there is a preponderance of bull speculation high terms are asked for the loan of money on the security of stock, termed a rate of *contango*, which may be expressed as so much per share or per cent. on the nominal hundred pounds of capital, or it may be a rate per cent. upon the actual amount of money to be borrowed. If many persons have formed an adverse opinion as to the course of the market, and there is what is termed an oversold state of the account, it frequently happens that those *bears* who have sold what they do not possess are called upon by real purchasers of stock, shares, or bonds to provide a bonus, termed *backwardation*, to pay the holder of the security for the trouble and risk attendant on lending it to the seller. Sometimes a long-continued speculation for the fall is attended with very high backwardation charges, and not infrequently violent fluctuations in the price of the security. Combinations to resist the adverse effect of sales by speculators for the fall are sometimes entered into in face of really adverse circumstances. A powerful group with command of money finding that 'bear' operations in a security of which the floating amount is small have been entered into to an excessively imprudent extent, buy all the stock that is offered, and call upon those who have sold what they do not possess to deliver it. This results in what is called a *corner*, and the operators who have sold have to pay whatever price the operators who have bought like to ask. *Corners* have been very frequent on the New York and Chicago Stock and Produce exchanges. It is many years ago since

any 'corner' of magnitude has been attempted on the London Exchange.

Much speculation in stock-exchange securities is conducted on what is known as *option* business. Options can be of threefold character—the payment of a sum for the right to purchase or to sell at a future date at an agreed price, or the right to sell only, or again the right to buy only. These options are termed respectively (1) the *put and call*, (2) the *put*, (3) the *call*. In America the double option of *put and call* is termed a *straddle*. This option business enables any operator to enter into speculative engagements with a known maximum of possible loss.

It should be mentioned that in 1878 a Royal Commission investigated and reported on the subject of the regulations and procedure of the Stock-exchange to consider *inter alia* the granting of a charter. The reports in full with evidence were published as a Government blue-book. It virtually commended the rules and regulations as they were being carried out by the committee of the Stock-exchange. At recurring intervals since then the 'charter' question has been revived, but so far nothing in this direction has been accomplished.

See Francis, *Chronicles of the Stock Exchange* (1849); G. R. Gibson, *The Stock Exchanges of London and New York* (1889); *Stock Exchange Official Intelligence*, issued annually under the sanction of the London Stock-exchange Committee, also the *Stock Exchange Year-book*, by T. Skinner; besides works by Crump (1875), Giffen (1877), Ellis (1879), Duguid (5th ed. 1926), Hartley Withers (1910), Poley (1911), Hirst (1911); on the law and usages of the Stock-exchange, works by Paterson, Royle, Melshemer, Lawrence, Stutfield, *Bagshot's Lombard Street* (10th ed. 1892), Schwabe and Branson (1905), J. Burn (1909), Bowes (1910), Parkinson's *ABC of Stocks and Shares* (1925), and American works by Lewis, Biddle, Dos Passos, and Cook; also the article BROKER.

Stock-fish, a commercial name of salted and dried cod and other fish of the same family, particularly the Ling, Hake, and Torsk.

Stockholm, the capital of the kingdom of Sweden, stands on several islands and the adjacent mainland, between a bay of the Baltic and Lake Mälär, in a situation that is accounted one of the most picturesque in Europe. The nucleus of Stockholm is an island in mid channel called 'the Town'; on it stand the imposing royal palace (1697-1754); the principal church (St Nicholas), in which the kings are crowned; the House of the Nobles (1648-70), in which that class held its periodical meetings; the ministries of the kingdom; and the principal wharf, a magnificent granite quay, fronting east. Immediately west of the central island lies the Knights' Island (*Riddarholm*), containing the old Franciscan church (restored 1914-22), in which all the later sovereigns of Sweden have been buried. To the north of these two islands lie the handsomely built districts of Norrmalm and Östermalm, separated from them by a narrow channel, in which is an islet with the Houses of Parliament. The principal buildings and institutions in Norrmalm and Östermalm are the National Museum (1850-65), with extremely valuable collections of prehistoric antiquities, coins, paintings, sculptures; the principal theatres; the Academy of the Fine Arts (1735); the barracks; the Hop Garden, a magnificent park, with the Royal Library (1870-76; a large collection), and

of Sciences (1739), with natural history collections; the Museum of Northern Antiquities (1873); the Observatory; the Nobel Library; and technological, medical, *slöjd*, and other schools. Ship Island (*Skeppsholm*), immediately east of 'the Town' island, is the headquarters of the Swedish navy, and is built over with marine workshops, ship-

building yards, &c., and is connected with a smaller island on the south-east, that is crowned with a citadel. Beyond these again, and further to the east, lies the beautiful island of *Djurgården*, once a hunting-ground of Gustavus Vasa. Situated there are the Northern Museum (1907), the Biological Museum, and a great open-air park and museum (*Skansen*). Immediately south of 'the Town' island is the extensive district of Södemalm, the houses of which climb up the steep slopes that rise from the water's edge. The new municipal buildings (1923) and the law-courts (1915), masterpieces of modern Swedish architecture, stand on the island of Kungsholmen. Handsome bridges connect the central islands with the northern and southern districts; besides buses and tramways, the principal means of communication are quick little steamboats, some of which extend their journeys to the beautiful islands in Lake Malar on the west, and eastward towards the Baltic Sea (40 miles distant). Besides the institutions already mentioned Stockholm is the home of the Swedish Academy (1786), Academies of Agriculture (1811), Music (1771), and the Military Sciences (1771), a naval school, a school of navigation, of pharmacy, &c. There is considerable industry in the making of sugar, tobacco, silks and ribbons, candles, linen, cotton, and leather, and there are large iron-foundries and machine-shops. Although Gothenburg is the chief port of Sweden, Stockholm, which ranks next, is the principal port of the east coast, and serves a vast hinterland. Usually free from ice on its seaward side all the year round, it has ample docking facilities, including six ship-yards with dry and floating docks, &c. A free-port area was established in 1919 and greatly extended in 1925. The most important imports are grain and flour, textile manufactures, raw textile material and yarn, colonial wares, and coal, while chief among the exports are timber (wrought and unwrought), iron and steel, metal goods, wood-pulp, paper and paper manufactures, and tar. Although Stockholm was founded by Birger Jäl about 1255, it was not made the capital of Sweden until comparatively modern times. It has grown rapidly: pop. (1800) 75,500; (1850) 93,000; (1870) 136,000; (1925) 438,896. The principal events in the history of the city have been the sieges by Queen Margaret of Denmark (1389), the battles in the vicinity against the Danes towards the end of the 15th century, the capture of the place by Christian II. of Denmark in 1520, the Blood Bath he executed amongst the principal men of the country in what was then the Great Market, and the liberation of the city by the Swedish patriot Gustavus Vasa in 1523.

Stockmar, CHRISTIAN FRIEDRICH, BARON, diplomatist, was born of Swedish descent at Coburg, 22d August 1787, studied medicine, and after some service with the army was appointed physician to Prince Leopold of Coburg, ere long to become his secretary and most influential adviser on all questions personal and political. As such he came to England with Leopold when he became the husband of the Princess Charlotte; and he gave Leopold valuable support in the negotiations that issued in making him king of Belgium. He had been ennobled in 1821, and was made a baron in 1831. Leaving Leopold's service in 1834, he became the mentor of Prince Albert of Coburg, and was the trusted friend of the young queen of England and her husband, living sometimes in England and sometimes in Coburg. As representative of Coburg in 1848 at the Diet, he supported Prussia's claim to the headship of the German nation. He died at Coburg, 9th July 1863.

See his *Denkwürdigkeiten*, edited by his son (F. trans. *Notabilia*, 2 vols. 1872); Juste, *Le Baron Stockmar* (Brussels, 1873); Sir Theodore Martin's *Life of the Prince Consort*; the Greville *Memoirs*; and for a less favourable view, the *Memoirs of King Leopold's morganatic wife*, Caroline von Bauer (Eng. trans. 1884).

Stockport, a parliamentary, municipal, and county borough of East Cheshire, 6 miles SSE. of Manchester and 37 E. of Liverpool. It is built on the slopes of a narrow gorge, where the Tame and the Goyt unite to form the Mersey, which is spanned by the viaduct (1840) of the London and North-Western Railway, 111 feet high and 625 yards long, as well as by several bridges. St Mary's Church was rebuilt in 1817, with the exception of its 14th-century chancel; and Stockport has also a market-hall (1851-61), mechanics' institute (1862), free library (1875), fine technical school (1890), large Union Sunday school (1806), grammar-school (1487; rebuilt 1832), infirmary (1832), the Vernon Park (1858), containing a museum, and, in St Peter's Square, a statue (1886) of Richard Cobden, who represented the borough from 1841 to 1847. Stockport was the site of a Roman station, and afterwards of a Norman castle, held till 1327 by the Earls of Chester, and taken by Prince Rupert in 1644, soon after which it was demolished by the parliament. In 1745 Prince Charles Edward passed through Stockport, which Bishop Peacock six years later describes as having 'a little manufacture of the Manchester linen, some woollen and ribbands, and two silk-mills like those of Derby.' Since then it has grown to be a most important seat of the cotton industry, in spite of the machinery disturbances (1810-20), the strike of 1828-29, when the military were called out, and many persons wounded, the 'Plug Riots' (1840), and the cotton-famine (1861-64). Felt hats are also manufactured, and there are iron and brass foundries, engine and machine shops, breweries, &c. Stockport was constituted a parliamentary borough (returning two members) in 1832, a municipal borough in 1835, and a county borough in 1888. Pop. (1851) 53,835; (1881) 59,553; (1901) 78,871; (1911) 119,870; (1921) 123,315.

Stocks, an apparatus of wood much used in former times in England for the punishment of petty offenders. The culprit was placed on a bench, with his ankles fastened in holes under a movable board, and allowed to remain there for an hour or two. The period of their first introduction is uncertain, but in the second Statute of Labourers, 25 Edw. III., 1350, provision is made for applying the stocks to unruly artificers; and in 1376 the Commons prayed Edward III. that stocks should be established in every village. Each parish had in later times its stocks, often close to the churchyard; and, though the last in London (St Clement Danes, Strand) were removed in 1826, many may still be seen in the country. Indeed the punishment was used so late as 1858 at Colchester, 1863 at Tavistock, and 1865 at Rugby. Combined with the stocks was often a whipping-post for the flagellation of vagrants.

Stocks. See NATIONAL DEBT, and STOCK-EXCHANGE.

Stockton, capital of San Joaquin county, California, on a navigable creek connected with the San Joaquin River, 103 miles by railway E. by N. of San Francisco. It contains a convent and the state lunatic asylum, and manufactures ironware, paper, woollens, flour, soap, carriages, farm implements, &c. Pop. 40,000.

Stockton, FRANCIS RICHARD, who was born at Philadelphia 5th April 1834, and died 19th April 1902, was engraver and journalist, and became assistant-editor of *St Nicholas*. He first attracted notice by

his fantastic stories for children, which fill several volumes; but he is best known by all classes of readers as author of *Rudder Grange* (1879). Later works are *The Late Mrs Null*, *The Casting Away*

(1894), *The Shadrach* (1895), *The Buccaneers and Pirates of our Coasts* (1898), and *Captain Chimp* (1898).

Stockton-on-Tees, a borough and seaport of Durham, on the north side of the Tees, 11 miles from its mouth and 11 ENE. of Darlington, 4 WSW. of Middlesbrough, and 236 NNW. of London. A new town, South Stockton, incorporated in 1892 as Thornaby-on-Tees (population 20,000), has sprung up in Yorkshire south of the river, the two being connected by an iron bridge of three arches (1887), which superseded a five-arch stone bridge of 1771, and cost over £80,000. The town has seven churches, a Roman Catholic chapel (1842-70) by the elder Pugin, a town hall, borough-hall (1852), an exchange, two theatres, large recreation grounds, and an extensive park presented by Sir Robert Ropner, Bart. The Stockton Races, of some mark in the sporting world, are held here annually in August. Shipbuilding, chiefly in iron and steel, is carried on to a great extent; and blast-furnaces, foundries, engine-works, and extensive potteries and ironworks are in operation. Sailcloth, ropes, linen, and dispers were at one time the staple industry of the town, but their manufacture has been discontinued; there are breweries. The exports are chiefly iron and steel manufactured, ferro-manganese, pig-iron, chemical manures, grain; the imports iron and steel manufactured and raw, spelter, sand and loam, chemical manures, cement, iron-ore, provisions and grain. The Stockton and Darlington Railway, the first to commence passenger traffic, was opened for the double purpose of the conveyance of passengers and goods, 27th September 1825. At Stockton the Tees is navigable for vessels of large tonnage; the navigation of the river has been much improved, and great facilities for an extensive trade provided. Pop. municipal borough (1891) 49,708; (1921) 64,150; of parliamentary borough, including Thornaby (1921) 83,981. Stockton suffered severely from the incursions of the Scots in the early part of the 14th century, but even at that time it enjoyed considerable trade. Its mounted castle was taken for the Parliament in 1644, and 'slighted and dismantled' in 1652, almost the last vestige being removed in 1865. At the Restoration it had only 120 houses, mostly built of clay. Since 1867 it sends one member to parliament. Ritson, Sheraton, and Walker (the inventor of friction matches) were natives.

Stoddard, RICHARD HENRY, American poet, was born at Hingham, Massachusetts, in July 1825, attended schools in New York, and then worked in an iron-foundry for some years, meanwhile reading widely, especially in poetry. In 1849 he produced a small volume of poems, only to suppress it afterwards; but 1852 saw the birth of a sturdier collection. From 1853 to 1870 he served in the New York custom-house, in 1870-73 was clerk to General McClellan, and till his death in May 1903 did much reviewing and literary criticism. His poems include *Songs in Summer* (1857), *The King's Bell* (1862), *The Book of the East* (1867), and *Lion's Cub* (1891).

Stoicism, a school of ancient philosophy, strongly opposed to Epicureanism in its views of human life and duty. The Stoical system dates from the end of the 4th century B.C.; though commonly said to have been derived from the system of the Cynics, it is noteworthy that few of its

founders or early apostles were born in Greece; it is the joint produce of Hellas and the Orient, and it was in Rome rather than in Greece that it most profoundly influenced civilisation.

The founder of the system was Zeno, from Citium in Cyprus (340-260 B.C.), who derived his first impulse from Crates the Cynic. He opened his school in a colonnade called the *Stoa Poikile* ('Painted Porch') at Athens, which was adorned with pictures of the Trojan war, Marathon, and the Amazons by Polygnotus; hence the name of the sect. Zeno had for his disciple Cleanthes, from Assos in the Troad (300-220), whose *Hymn to Jupiter* is the only fragment of any length that has come down to us from the early Stoics—a poem setting forth the unity of God, his omnipotence, and his moral government. Chrysippus, from Soli in Cilicia (280-207), followed Cleanthes, and in his voluminous writings both defended and modified the Stoical creed. Antiquity gave by far the most important position to Chrysippus: 'Without Chrysippus there had been no Porch'; recent German criticism has done much to discover how much of the system is due to each. And Pearson sums up his elaborate investigation as follows: 'The result of our investigation has been to show conclusively that all those doctrines which are most characteristic of the true essence of Stoicism were contributed by Zeno and Cleanthes. To Zeno belong the establishment of the logical criterion, the adaptation of Heraclitean physics, and the introduction of all the leading ethical tenets. Cleanthes revolutionised the study of physics by the theory of tension and the development of pantheism, and by applying his materialistic views to logic and ethics brought into strong light the mutual interdependence of the three branches. The task of Chrysippus was to preserve rather than to originate, to reconcile inconsistencies, to remove superfluous outgrowths, and to maintain an unbroken line of defence against his adversaries.' These three represent the first period of the system. The second period (200-50) embraces its general promulgation, and its introduction to the Romans. Chrysippus was succeeded by Zeno of Sidon, and Diogenes of Babylon; then followed Antipater of Tarsus, who taught Panætius of Rhodes, who, again, taught Posidonius of Apamea, in Syria. Posidonius was acquainted with Marius and Pompey, and taught Cicero; but the moral treatise of Cicero, *De Officiis*, is derived from a work of Panætius. The third period of Stoicism is Roman. In this period we have Cato the Younger, who invited to his house the philosopher Athenodorus; and, under the Empire, the three Stoic philosophers whose writings have come down to us—Seneca, Epictetus, and the Emperor Marcus Aurelius. Stoicism prevailed widely in the Roman world, although not to the exclusion of Epicurean views.

The leading Stoical doctrines are given in certain phrases or expressions, as 'life according to nature,' the ideal 'wise man,' 'apaty,' or equanimity of mind, the power of the 'will,' the worship of 'duty,' the constant 'advance' in virtue, &c. But the system will be best considered under four heads—the Theology; the Psychology; the theory of the Good; and the scheme of Virtue.

(1) The Stoics held that the universe is governed by one good and wise God. According to Epictetus, God is the father of men; Marcus Aurelius exults in the beautiful arrangement of all things. They did not admit that the Deity intermeddled in the smaller details of life; they allowed that omens and oracles might be accepted as signs of the foreordained arrangement of God. They held this foreordination even to the length of fatalism, and made the same replies as have been given in

modern times to the difficulty of reconciling it with Free-will. God is the author of all things except wickedness; the very nature of good supposes its contrast evil, and the two are inseparable, like light and dark; in the enormous extent of the universe some things must be neglected; when evil happens to the good, it is not as a punishment, but as connected with a different dispensation; parts of the world may be presided over by evil demons; what we call evil may not be evil. Like most other ancient schools, the Stoics held God to be corporeal like man; body is the only substance; nothing incorporeal could act on what is corporeal; the first cause of all, God or Zens, is the primeval fire, emanating from which is the soul of man in the form of a warm ether. Their theory of the universe may in fact be described as a materialistic pantheism. It is for human beings to recognise the universe as governed by universal law, and not only to raise their minds to the comprehension of it, but to enter into the views of the Creator, who must regard all interests equally; man should be, as it were, in league with Him, merge self in the universal order, think only of that and its welfare. By this elevation of view we are necessarily raised far above the consideration of the petty events befalling ourselves. The grand effort of human reason is thus to rise to the abstraction or totality of entire nature. The Stoics held the theory of the *absorption* of the individual soul at death into the divine essence; but, on the other hand, their doctrine of advance and aspiration is what has in all times been the main natural argument for the immortality of the soul. For the most part they kept themselves undecided as to immortality, giving it as an alternative, but reasoning as to our conduct on either supposition, and submitting to the pleasure of God in this as in all other things. In arguing for the existence of divine power and government they employed what has been called the argument from design.

(2) As to the constitution of the mind, they held that men have bodies like animals, but reason or intelligence like the gods. Animals have instinctive principles of action; man alone has a rational, intelligent soul. According to Marcus Aurelius, we come into contact with Deity by our intellectual part, and our highest life is thus the divine life. But the most important Stoical doctrine respecting the nature of man is the recognition of reason as a superior power or faculty that subordinates all the rest—the governing intelligence. This, however, is not a mere intellectual principle, but an active force, uniting intellect and will. The bodily sensibilities are opposed to this higher reason and will, which, however, is strong enough to control them. Another way of expressing the same view was the power of the mind over the body, which was dwelt upon by Epictetus in the most exaggerated form. (The assertion of a doctrine so obviously contrary to the fact as that sickness may affect the body without enfeebling the mind could only end in practical failure, or else in contradiction.) In Seneca we find something very closely approaching to the Christian doctrine of the corruption of human nature. The littleness of humanity was a favourite theme of Marcus Aurelius, and naturally followed from the Stoical mode of contemplating the universe at large. The doctrine called the freedom of will may be said to have originated with the Stoics, although with them it was chiefly a rhetorical mode of expressing the dignity of the wise man, and his power of rising superior to circumstances. To prepare the way for the Stoical precepts Epictetus distinguished between things in our power and things not in our power. The things in our power are our opinions and notions about objects, and all our affections, desires, and aversions; the things not

in our power are our bodies, wealth, honour, rank, authority, &c. Wealth and high rank may not be in our power, but we have the power to form an idea of these—viz. that they are unimportant, whence the want of them will not grieve us. A still more pointed application is to death, whose force is entirely in the idea.

(3) The Good was not by the Stoics identified with happiness. Happiness is not necessary, and may be dispensed with, and pain is no evil. Pains are in a sense an evil, but, by a proper discipline, may be triumphed over. They disallowed the direct and ostensible pursuit of pleasure as an end (the point of view of Epicurus), but allured their followers partly by promising them the victory over pain, and partly by the lofty enjoyments that grew out of their plan of life. Pain of every kind, whether from the casualties of existence or from the severity of the Stoical virtues, was to be met by a discipline of endurance. Great stress was laid on the instability of pleasure, and the constant liability to accidents; whence we should always be anticipating and adapting ourselves to the worst that could happen, so as never to be in a state where anything could ruffle the mind. Much might still be made of the worst circumstances—poverty, banishment, public odium, sickness, old age. Such a discipline was peculiarly suited to the unsettled condition of the world at the time, when any man, besides the ordinary evils of life, might in a moment be sent into exile, or sold into slavery. Moreover, it is a discipline adapted to a certain class of dispositions existing in all ages—men who prefer above all things ‘equanimity’ of mind, and would rather dispense with great occasional pleasures than risk their state of habitual composure. Next to the discipline of endurance we must rank the complacent sentiment of pride, which the Stoic might justly feel in his conquest of himself. It was usual to bestow the most extravagant laudation on the ‘wise man,’ and every Stoic could take this home to the extent that he considered himself as approaching that great ideal. The last and most elevated form of Stoical happiness was the satisfaction of contemplating the universe and God. The work of Marcus Aurelius is full of studies of nature in the devout spirit of ‘passing from nature to nature’s God;’ he is never weary of expressing his thorough contentment with the course of natural events, and his sense of the beauties and fitness of everything. Old age has its grace, and death is the becoming termination. This high strain of exalting contemplation reconciled him to that complete submission to whatever might befall which was the essential feature of the ‘life according to nature.’

(4) The Stoical theory of virtue is implicated in their ideas of the good. The fountain of all virtue is manifestly the life according to nature, as being the life of subordination of self to more general interests—to family, country, mankind, the whole universe. The Stoics were the first to preach what is called ‘Cosmopolitanism;’ for although, in their reference to the good of the whole, they confounded together sentient life and inanimate objects—rocks, plants, &c., solitude for which was mispent labour yet they were thus enabled to reach the conception of the universal brotherhood of mankind, and could not but include in their regards the brute creation. They said, ‘There is no difference between Greeks and Barbarians; the world is our city.’ Seneca urges kindness to slaves, for ‘are they not men like ourselves, breathing the same air, living and dying like ourselves?’ The Epicureans declined, as much as possible, interference in public affairs, but the Stoical philosophers all urged men to the duties of active

citizenship. Although there had been many good and noble men among the pagans, yet positive beneficence had not been preached as a virtue before the Stoics. They adopted the four cardinal virtues (wisdom, or the knowledge of good and evil; justice; fortitude; temperance) as part of their plan of the virtuous life. Justice, as the social virtue, was placed above all the rest; but most interesting to us are the indications of the idea of beneficence. Epictetus is earnest in his exhortations to forgiveness of injuries. Marcus Aurelius often enforces the same virtue; he contends as strongly as Butler and Hume for the existence of a principle of pure—that is, unselfish—benevolence in the mind. There is also in the Stoical system a recognition of duties to God, and of morality as based on piety. Not only are we all brethren, but also the 'children of one Father.'

The extraordinary stress put upon human nature by the full Stoic ideal of submerging self in the larger interests of being led to various compromises. The rigid following out of the ideal issued in a series of the Paradoxes—viz. that all the actions of the wise man are equally perfect, and that, short of the standard of perfection, all faults and vices are equal; that, for example, the man that killed a cock without good reason was as guilty as he that killed his father. The idea of duty was of Stoical origin, fostered and developed by the Roman spirit and legislation. The early Stoic had two different words for the 'suitable' (*kathêkon*) and the 'right' (*katorthôna*). It was a great point with the Stoic to be conscious of 'advance,' or improvement. By self-examination he kept himself constantly acquainted with his moral state, and it was both his duty and his satisfaction to be approaching to the ideal of the perfect man. The Stoical system has largely tinted modern ages, in spite of its severity. It has always had a charm as an ideal, even when men were conscious of not realising it. The limitation of wants, the practice of contentment, the striving after equanimity, the hardening of one's self against the blows of fortune are all fundamental maxims with the moralists of later ages; and a qualified form of the subordination of self to the general welfare is an essential part of most modern theories of virtue.

The chief ancient authorities on the Stoics are the writings of Epictetus, Marcus Aurelius, and Seneca, themselves Stoic philosophers, together with notices occurring in Cicero, Plutarch, Sextus Empiricus, Diogenes Laërtius, and Stobæus. See Zeller's *Stoics, Epicureans, and Sceptics* (Eng. trans. 1870); L. Alston, *Christian Stoicism in the Second Century* (1906); Edwyn Bevan, *Stoics and Sceptics* (1913) and 'Philosophy' in *The Hellenistic Age* (1924); Gilbert Murray, *Stoic Philosophy* (1915); and *Five Stages of Greek Religion* (1925); Wouley, *Stoicism and its Influence* (1925); and works cited at AURELIUS, EPICTETUS, SENECA, ZENO.

Stoke-Newington, a metropolitan borough in the north of London, wedged between Islington and Hackney, returns one member to parliament. Pop. (1921) 52,167.

Stoke-on-Trent, a city, county, and parliamentary borough of Staffordshire, the capital of the 'Potteries,' on the Trent and the Trent and Mersey Canal, an important railway centre, 15 miles SE. of Crewe, 2 E. of Newcastle-under-Lyme, and 16 N. of Stafford. It was formed in 1910 by the union of Hanley, Burslem, Tunstall, Longton, and Fenton with Stoke-upon-Trent, and was declared a city in 1925. It became a three-member parliamentary borough in 1918, the parliamentary divisions being Burslem, Hanley, and Stoke. Stoke-upon-Trent is a modern place, dating only from the last quarter of the 18th century, and has a

parish church with Wedgwood's grave, a town-hall (1835), a market-hall (1883), a free library (1878), the Minton memorial building (1858), the Harris-hill Infirmary (1868), public baths, and statues of Wedgwood, Minton, and Colin Minton Campbell. Its factories of porcelain, earthenware, encaustic tiles, and tessellated pavements are among the largest in the world; and the industries also include coal-mining, brickmaking, and the manufacture of iron, engines, machinery, &c. The Central School of Science and Technology, an institution for training in the industries of pottery and coal-mining, was opened in 1914, and extensions were commenced in 1925. There is a collection of pottery housed in the public library and museum, and a similar collection at Hanley. Other important schools of technology are the Wedgwood Institute at Burslem, the Sutherland Institute at Longton, and the Victoria Institute at Tunstall. Longton (once called Lane End) and Fenton (once called Lane Delph) are both busy centres of china and earthenware manufacture. See separate articles on HANLEY, BURSLEM, and TUNSTALL. Pop. of Stoke-on-Trent county borough (1911) 234,534; (1921) 240,440.

Stoke-Poges, a village of Buckinghamshire, 2 miles N. of Slough station. Gray's mother settled here in 1742, and he is buried in the beautiful churchyard, the scene of his *Elegy*.

Stokes, SIR GEORGE GABRIEL, mathematician and natural philosopher, was born August 13, 1819, in Skreen, County Sligo. He entered Pembroke College, Cambridge, in 1837, graduated in 1841 as senior wrangler and first Smith's prizeman, and in 1849 was appointed Lucasian professor of Mathematics. In 1852, the year after his election as a Fellow of the Royal Society, he was awarded the Rumford medal; in 1854 he became secretary, a position which he held till 1885, when he was made president for the succeeding quinquennial period. From 1886 he represented Cambridge in parliament, and in 1889 was created a baronet. His papers deal with some of the most abstruse problems of mathematical physics, and are characterised by a remarkable lucidity of treatment and an unerring sagacity of attack. In several of these, by opening new ground, he gave direction to later investigations by others. Till his death (1st February 1903) two subjects mainly engaged his attention. On Hydrodynamics he wrote for the British Association in 1846 a valuable Report, in which his own contributions rank amongst the most important of the day. Specially may be noted his investigations on waves and on the effect of fluid friction on solids moving through fluids. Then to the theory of light he made contributions of great value, his profound paper on the dynamical theory of diffraction (1849) being amongst the most important. He first gave a satisfactory theory of fluorescence and phosphorescence, and as early as 1852 he pointed out clearly the physical basis of Spectrum-analysis (see SPECTRUM). In 1884-86 he delivered in Aberdeen the Burnett Lectures on 'Light' (3 vols. 1887), an admirable elementary treatise for non-mathematical readers. His influence in the development of the Cambridge school of mathematical physics can hardly be overestimated.

See his *Mathematical and Physical Papers* (5 vols. 1880-1905), *Memoir and Correspondence*, ed. Larmor (2 vols. 1907).

Stokes, WILLIAM (1804-77), physician, studied at Edinburgh, and in 1845 became regius professor of Medicine in Dublin University. He wrote lectures on the *Theory and Practice of Medicine* (1837), and works on the diseases of the chest and of the heart and on continued fevers.—His eldest son, WHITLEY

STOKES, born at Dublin in 1830, studied law at Trinity College, went to India in 1863, and after holding a series of important legal appointments was in 1877-82 president of the Indian law-commission and draughtsman of the present civil and criminal codes. He wrote many legal works, including *The Anglo-Indian Codes* (1887-91), and edited many Irish and other Celtic texts. LL.D., D.C.L., C.S.L., C.I.E., he died 13th April 1909.

Stoke-upon-Trent, since 1910 part of Stoke-on-Trent (q.v.).

Stolberg, **CHRISTIAN**, **GRAF ZU**, poetic writer, was born at Hamburg, 15th October 1748. Whilst a student at Göttingen he identified himself with the Göttingen poetic school (*Dichterband*), a literary circle embracing also Bürger and Voss. After twenty-three years' public service in the duchy of Holstein he retired, and died at his seat of Windelove, near Eckenförde in Sleswick, on 18th January 1821. As a poet he was inferior in genius to his brother Friedrich Leopold, in whose books his own work was generally included. His principal productions are *Gedichte* (1779), *Gedichte aus dem Griechischen* (1782), *Schauspiele mit Chören* (1787), *Vaterländische Gedichte* (1810), and a metrical translation of Sophocles (1787).

Stolberg, **FRIEDRICH LEOPOLD**, **GRAF ZU**, younger brother of the preceding, was born at Braunstedt in Holstein on November 7, 1750. Like his brother he was one of the *Dichterband* fraternity at Göttingen. Most of his active life was spent in the public service of Denmark. Although possessed of some degree of poetic fancy, he was on the whole a somewhat colourless writer in the style of Klopstock. Shortly after the outbreak of the French Revolution he went over to the Roman Catholic Church, and from that time a very pronounced religious and ascetic temper made itself prominent in his writings, of which the principal was *Geschichte der Religion Jesu Christi* (15 vols. 1807-18). He died on his estate of Sondernmühlen, near Osnabrück, 5th December 1819. Besides the volumes of *Gedichte*, *Schauspiele*, *Vaterländische Gedichte*, issued along with his brother's works, F. L. Stolberg published translations from *Æschylus*, *Plato*, and the *Iliad*, an idyllic romance *Die Insel* (1788), and other books. See works by Menge (1863), Henness (1876), Janssen (3d ed. 1882), Sauer (1895).

Stole (Gr. *stolē*, Lat. *stola*, 'a robe'), a narrow vestment, of the same stuff as the chasuble, worn by bishops and priests in the Latin Church during mass, in the administration of sacraments, and in certain blessings, and by deacons when they have to move the blessed sacrament. In some places it is worn while preaching. Bishops wear it over both shoulders; so also do priests, but crossed over the breast; deacons wear it over the left shoulder. It is also used in some cases as a symbol of jurisdiction, in which sense it is constantly worn by the pope, even when not officiating. In the Anglican Church the stole is worn with the same difference by priests (but not crossed) and deacons. It is usually of black silk, fringed at the ends, with sometimes crosses embroidered; but coloured stoles, according to the season, are also worn in some churches. In the Greek Church the stole proper is peculiar to deacons; among Syrian Christians it is worn by clerics of all (even minor) orders. The stole originated in the *orarium* or handkerchief, which was sometimes worn as a scarf, and which in the 6th and 7th centuries came to be recognised as a sacred vestment in the Western Church. The name stole began to be substituted by the 9th, and was the common word before the 12th century. See illustrations at CHASUBLE and COTE. *Stole-fees* are the same as surplice-fees (see SURPLICE). The

broad scarf is worn by chaplains to any member of the royal family, or to any peer or peeress, doctors in divinity, and capitular members of a collegiate church.

Stolen Goods are thus treated by English law: a *bond-fide* purchaser of such goods, who has not bought them in market overt, is bound to restore them to the true owner; but if the goods are sold in market overt, the purchaser is entitled to keep them unless the owner has duly prosecuted and convicted the thief. Market overt means the open market in towns and places where a legal market is held. In the City of London every shop is held to be a market overt, but this only applies to the City proper (see SALE). The above rule as to stolen goods does not apply to valuable securities which are stolen, if the security has been paid or discharged *bond fide* by the person liable, or if the security is a negotiable instrument and has passed to a 'holder in due course.' It is a punishable offence to offer or take rewards for the recovery of stolen property. See also THEFT.

Stolp, a town in the Prussian province of Pomerania, stands on the river Stolp, 8½ miles W. by N. of Danzig, and has a castle, some old churches (the castle chapel dating from the 13th century), non-foundries, machinery and amber manufactures, and an active trade in agricultural products, timber, fish, &c.: pop. (1925) 41,826.

Stolypin, **PETER ARKADIEVITCH** (1865-1911), the indomitable Russian minister who repressed disorder with a high-hand, dissolved the second Duma (1907), altered the electoral law, and, in spite of the council of the empire, promulgated a measure of Polish reconstruction passed by his majority in the third Duma. He fell by the hand of an assassin.

Stomach. The Anatomy and Physiology of this organ are treated of in the article DIGESTION (q.v.); see also ABDOMEN, BIRD, FISHES, &c.; and INDIGESTION, VOMITING.

DISEASES OF THE STOMACH.—Only the more common and severe varieties of gastric disease will be treated here. The symptom that is most frequently noticed by the subject of stomach disturbance is dyspepsia, which may in some cases amount to severe pain connected with the taking of food or coming on some hours later, or which may consist simply of a feeling of weight, distension, or general discomfort about the middle of the body. Vomiting accompanies some of the severer disorders, and blood may at times be brought up in the vomit or passed in the motions of the bowels. Loss of weight is found in the more serious conditions, but if the nutrition of the body be well maintained, the disease is not likely to be of grave importance apart from the discomfort that it occasions. In the diagnosis of gastric disease, valuable information is obtained from chemical examination of a light test-meal drawn off by the stomach tube after an hour's digestion; and in cases of alteration in shape or position of the organ, direct evidence as to its condition is given by the administration of a meal containing bismuth or other dense substance which is then subjected to examination by the X-rays.

Acute gastritis (inflammation of the stomach) is most commonly caused by errors in diet, such as indigestibility of the food, strong spirituous liquors, extremes of temperature in the food, or food in a state of decomposition. It is also one of the features in poisoning by an irritant (see POISON). In some persons it is produced by sudden changes in the weather, or even occurs periodically as so-called 'bilious attacks.' The chief symptoms of acute gastritis are pain in the stomach, varying according to the severity of the irritation from a feeling of weight to one of great agony, also head-

ache, sour eructations, vomiting first of food and later of bile-stained material, and finally there may be diarrhoea from irritation of the bowels. The treatment consists in getting rid of the irritating material either by an emetic or by a purgative according to circumstances; the administration of remedies which have a soothing effect upon the gastric mucous membrane, such as bismuth carbonate, weak alkaline fluids, and preparations of opium; the application to the surface over the stomach of mustard leaves, hot compresses, or other forms of counter-irritation; and the abstinence at first from all forms of food and afterwards for a few days from anything heavier than milk or light farinaceous foods.

Chronic gastritis (chronic catarrh) may arise after repeated attacks of the acute form or may come on gradually as the result of injudicious dietary, such as irregularity in meal times, habitual use of irritating foods or of strong forms of alcohol, or as the result of weakening disease in other organs. It may present various symptoms. In some cases it is associated with an excessively acid gastric juice, when discomfort is felt in the pit of the stomach an hour or more after food, later a burning sensation (heartburn) about the centre of the chest, and often eructation in small quantities of intensely acid food causing a raw feeling in the throat, or less commonly vomiting of the sour stomach-contents in large quantities. In other cases, especially those of long duration and those due to spirit-drinking, gastritis is associated with a poor secretion of gastric juice and small appetite, the tongue is furred, and there is occasional vomiting, especially in the morning, of food remnants with strings of mucus. In treatment, attention to the diet is the most important point. The meals must be taken regularly, and small meals at relatively frequent intervals are preferable to occasional large amounts of food. In all cases careful attention to the teeth, if these are decayed or defective, and proper chewing of the food are of great importance. Regularity of the bowels, early rising, and sufficient daily exercise in the fresh air must also be practised. In the acid form of gastritis, all condiments, even salt, should be avoided as much as possible, and the food should be simple and non-stimulating, such as eggs, fish, vegetable soups, milk puddings, and the like; meat and strong meat-soups should be avoided. In the form where appetite is poor and there is vomiting of mucus in the morning, salted food, pickles, and condiments like mustard and pepper stimulate the stomach and act beneficially; meat well-divided is also allowable. As to medicinal remedies, in the acid type of gastritis rhubarb, soda, and bismuth, combined sometimes with Dover's powder when the pain is severe, may be taken before meals; or a bitter infusion, such as that of gentian or calumba, combined with bicarbonate of soda, taken similarly before meals, often gives much relief. In the type of case with mucus and poor appetite, a better result is got usually from taking one of these bitter infusions combined with dilute hydrochloric acid immediately after each meal.

Dilatation of the stomach (gastrectasis) may either occur as a natural condition or may arise from weakness in the muscular wall or from some obstruction to the exit of the stomach-contents at the pyloric opening. Great capacity of this organ is compatible with perfect health, but when the food cannot properly escape and is retained for many hours, various forms of fermentation are apt to occur and to cause discomfort and failure of proper nutrition. In its early stage this condition is known as *atony of the stomach*, and when the condition is due to a slipping down of the whole

organ from its attachments the term *gastropexia* is employed. However the distension may be brought about, the ultimate result is that the lowest part of the stomach descends so far beneath the outlet that natural emptying of the organ into the small intestine becomes increasingly difficult, and the stomach distends more and more under the increasing load. These cases are particularly easily recognised on X-ray examination. In the milder cases, tonic treatment, the avoidance of bulky forms of food, and the wearing of a broad, carefully-shaped abdominal belt or binder may suffice. In severer cases, where the stomach has become so much distended that complete emptying never takes place, fermentation occurs, and there is a constant feeling of heartburn and of weight beneath the ribs; vomiting of fermented material in great quantity takes place every few days, followed by a sense of relief in the symptoms; constipation is very troublesome owing to the delay in digestion; and the patient loses greatly in weight and strength. The special treatment required by these severer cases consists in washing out the stomach either at night or in the morning with the stomach-tube. In exceptionally severe cases, due, for example, to narrowing of the pyloric outlet by the scar of an old ulcer, the operation of gastro-enterostomy often affords relief from all the symptoms. This consists in uniting the lowest part of the stomach to a neighbouring loop of bowel with an opening passing from the one to the other, so that effective escape of the stomach-contents is ensured.

Ulcer of the stomach (gastric ulcer) is a frequent disease sometimes existing unsuspected for a long time on account of the mildness of its symptoms, and in other cases constituting a very formidable pathology. Its frequency may be judged from the fact that post-mortem examinations show one person in every twenty or twenty-five to have either an acute ulcer or the scars of a healed ulcer dating from some previous period of life. The disease is more common in women than in men, affecting especially young women between the ages of twenty and thirty; and it is frequently associated with anaemia. The ulcer is usually small ($\frac{1}{2}$ to $\frac{1}{2}$ inch in diameter), of round or oval form, and has a tendency to penetrate through all the coats of the stomach. It is most commonly found on the hinder wall of the stomach close to the pyloric orifice or beyond this in the duodenum. It may heal at any stage, and, if it is small, practically no trace may be left; or if it has been large, a great deal of scarring may result, which is apt to cause narrowing of the pyloric opening with consequent dilatation of the stomach. In occasional cases one of two serious complications may ensue, and the possibility of these makes the condition always dangerous: either the ulcer may erode a blood-vessel with resulting hemorrhage into the stomach, or it may perforate into the peritoneal cavity, producing acute peritonitis of sudden onset. The symptoms of gastric ulcer, as already indicated, may be mild and indefinite, but usually there is considerable pain, especially after solid food has been taken. This pain, together with tenderness on pressure, is chiefly found in the pit of the stomach, just below the lower end of the breast-bone, but occasionally the pain is referred through to the back. Vomiting of blood either in streaks or as large quantities of material resembling coffee-grounds, or the passing of black partially-digested blood by the bowels, is a very characteristic sign. In treatment the most important principle is to give the stomach complete rest, and to administer only sufficient food to absorb the acid gastric juice. Milk, with the addition of lime-water and cream and thin starchy foods like

arrowroot, ground-rice, or cornflour, are the most suitable. In severe cases the patient remains in bed, and nourishment by the bowel is employed over two or three weeks, later small quantities of milk and cream or of white of egg in water being given by the mouth. The most serviceable medicinal remedies are large doses of bismuth carbonate, with which may be joined small doses of opium or of dilute hydrocyanic acid to relieve the pain. When hæmorrhage occurs, it is checked by sucking small lumps of ice and by such styptics as tannin, ergot, and extract of suprarenal gland. When small hæmorrhages persist in spite of treatment, the operation of gastro-enterostomy is often performed in order to prevent the passage of food over the ulcer. If perforation should occur, an immediate operation to close the opening is urgently necessary.

Cancer of the stomach occurs mostly in people over fifty years of age, and a hereditary tendency to the disease can often be traced. It usually commences near one or other of the openings of the stomach; and if it is at the pyloric opening, an obstruction is presented to the escape of food, so that dilatation of the stomach ensues with great aggravation of the patient's symptoms. Sooner or later the growth ulcerates, and bleeding then usually occurs. The symptoms at an early stage are dyspepsia, loss of weight, with pain, discomfort and vomiting after meals, and the vomit often shows the presence of blood. The diagnosis is rendered more certain when a tumour can be felt over the region of the stomach, and when chemical analysis of a test-meal reveals the absence of the normal hydrochloric acid from the gastric secretion. X-ray examination frequently affords a certain amount of help in diagnosis. In early cases an operation can sometimes be performed which completely removes the disease; and in more advanced cases the measures applicable to dilatation of the stomach, with opium and other drugs to relieve pain, and with care in the dietary, afford relief. The duration of life in a case of gastric cancer is usually from six to twelve months.

Vomiting of blood (hæmatemesis) is an important sign of disease affecting the stomach. It may be due to erosion of a large blood-vessel in the course of gastric ulcer or of cancer, but it usually occurs in these diseases by gradual oozing from the minute vessels (capillaries) over the bare surface. It frequently takes place without any apparent breach of surface when strong irritants are taken by the mouth, such as an irritant poison or an immoderate dose of strong alcohol. It also arises in the course of general diseases associated with hæmorrhage elsewhere, such as scurvy and pernicious anemia, or it may be a vicarious form of the menstrual discharge. Occasionally, in diseases of neighbouring organs, such as the liver and the heart, varicose veins are found in the stomach, which, by their rupture, give rise to copious hæmatemesis without actual disease of the stomach. The treatment of vomiting of blood is given above under Ulcer.

Stomata, minute openings in the epidermis of leaves and tender green stems of plants, subserve the purposes of respiration, transpiration, and gas-assimilation. They are most numerous on the under surface in most leaves, on the upper side of floating leaves, but in some monocotyledons equally distributed. See PHYSIOLOGY (VEGETABLE), and illustration at LEAF; and for the complex stomata of *Marchantia*, see LIVERWORTS.

Stone, a market-town of Staffordshire, on the left bank of the Trent, 7 miles NNW. of Stafford and 7 S. of Stoke-on-Trent. It has a town-hall (1869), a market-hall (1868), Alleyne's grammar-school (1558), remains of an Augustinian monas-

tery, two modern convents, and manufactures of earthenware, boots and shoes, beer, leather, &c. Pop. 6000.

Stone, a weight formerly in use throughout the northern countries in Europe, but varying in different countries, and now mostly obsolete. The British imperial stone, the only legal one, is 14 lb.; but in various parts of the country stones of other values are or have been in use, as a stone of 24 lb. for wool, 8 lb. for butcher-meat, 22 lb. for hay, 7 lb. for oatmeal in Scotland, 16 lb. for cheese, 32 lb. for hemp, and 5 lb. for glass.

Stone. See CALCULUS, and LITHOTOMY.

Stone. Under the head BUILDING STONE, the more important kinds of stone used for architectural purposes are noticed. The preservation and dressing of stone are also treated there, as is artificial stone. Some building-stones, such as limestone, marble, sandstone, flagstone, flint, slate, granite, basalt (green-stone), serpentine, and porphyry, are again referred to under their respective names. See under MILL, OVEN, and WHEAT-STONES for millstones, firestone (leekstone), and hones. Precious stones are discussed under STONES (PRECIOUS), and such heads as DIAMOND, RUBY, SAPPHIRE. For the art of carving precious stones, see CAMEO, GEM. Purely ornamental stones other than gems are noticed under ALABASTER, FLUOR SPAR, JADE, JASPER, LABRADORITE, LAPIS LAZULI, MALACHITE, and other heads.

Stone AGE, or AGE OF STONE, is a term used in archaeology to denote the condition of a people who, being unacquainted with the arts of working in metals, are obliged to use stone of various kinds as the material from which to manufacture cutting tools and weapons. *Stone Stage* would perhaps be a more correct expression. The word 'Age' must not be here understood to mean a fixed chronological epoch in the world's history; it merely implies the time, long or short, early or late, during which the condition specified subsisted in any region or among any population. Its duration necessarily varied with circumstances in different centres. Peoples settled in remote situations, and therefore uninfluenced by contact with higher phases of culture (as, for example, the islanders of the South Pacific, and the Eskimo of the extreme north), have in some cases remained in their Stone Age down to the 19th century; whereas the peoples of Europe, in various parts of which high civilisations developed at an early date, emerged from their Stone Age by acquiring the art of working bronze many centuries before the Christian era. That throughout all Europe man has begun with an Age of Stone is certain. We cannot be quite so sure about certain regions of the other continents, which as yet are insufficiently explored; but evidence of a primeval Age of Stone has come from Asia Minor, India, China, various parts of Africa, and also from the American continent.

The beginning of human life in Europe has been sought in Tertiary times. Pliocene and even Miocene gravels have yielded chipped flints which have been considered to be the work of a sentient being, whether fully developed man or an antecedent Homosinian form is disputed. An influential school of prehistoric archaeologists, however, deny that these *coliths*, as they are called, display any assured indication of intentional chipping, and assign their origin to one or other of various natural causes. The flints are at best so rude that it is really impossible to feel any certainty about their artificial character; nothing will ever settle this dispute but the discovery of bones of their supposed makers. Such a discovery has never yet been made.

That man occupied Europe during some at least

of the phases of the Quaternary ice age is, however, quite beyond question; recognisably artificial flint implements have been found, associated in some cases with the bones of animals then living in Europe, but now extinct. During the Ice Age, in its alternating glacial and genial intervals, man lived entirely upon the products of the chase. He was unacquainted with the arts of agriculture, as is shown by the absence of millstones and similar agricultural implements, and also by the absence of the bones of domestic animals from his habitation sites and middens; he was also ignorant of the art of weaving, as is shown in like manner by the absence of spindle-whorls and loom-weights;

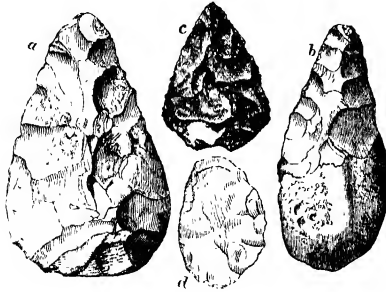

Fig. 1.

a, round-pointed, tongue-shaped implement, Biddenham, near Bedford; *b*, acutely-pointed implement made from rounded nodule of flint, St Acheul, near Amiens; *c*, from Bomerton, Wilts; *d*, irregularly-ovate, flat-topped instrument, Monlin Quignon, Abbeville. (From Evans's *Ancient Stone Implements of Great Britain*.)

there is, moreover, no evidence that he knew how to make pottery. During the centuries which intervened between the ice age and the beginning of the use of metal, the arts specified above were acquired step by step. The earlier stage, during which man was a hunter, is known as the *Palaeolithic*, or Old Stone Age; the latter is the *Neolithic*, or New Stone Age. It is a mistake to suppose that the Neolithic age is essentially a period of polished stone, though it is not infrequently so called; the majority of the Neolithic implements are clipped often as rudely as in the antecedent Palaeolithic, and many of the implements of polished stone, formerly assigned to the Neolithic, are now known to belong

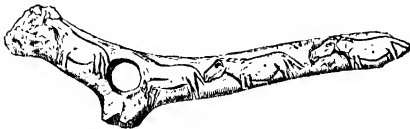

Fig. 2.—Carved Reindeer-horn, Lauzeriesbasse, Dordogne. (From Cartailhac's *La France Préhistorique*.)

to the Bronze Age. The essential distinction between the two periods lies in the differences between their respective modes of life.

The Palaeolithic age was of enormous duration, although it is impossible to fix its length in terms of years. The Heidelberg jawbone, probably the earliest human relic as yet found in Europe, is by some dated to *circa* 382,000 B.C.; but dates such as this have no real meaning. For chronological purposes the Palaeolithic has been divided into a series of subordinate periods, which apparently indicate chronologically successive stages of civilisation.

The division holds satisfactorily for western Europe, but it is by no means so easily applied to the remains which have been yielded by the eastern regions of the Continent. These divisions are as follows:

1. *Pre-Chellean*.—An introductory stage represented by very rude, almost amorphous implements.

2. *Chellean* (so called from the typical station of Chelles-sur-Marne, near Paris).—A period when Europe was sufficiently tropical in climate to support such animals as the hippopotamus. Man is represented by tools of flint embedded in the river-drifts. The chief tool is the *coup de poing*, or hand-axe—a nodule of flint sharpened at one end, rounded at the other for convenience of grasping in the hand.

3. *Acheulean* (named after the typical station of Saint-Acheul, near Amiens), during which the climate was growing colder; the tropical animals were giving place to the mammoth. The tools, especially the *coup de poing*, are better made than in the preceding period.

These three together constitute the *Lower Palaeolithic*, and are probably to be dated in the genial period between the Riss and the Würm glaciations, the last two great advances of the Ice Age.

4. *Monsterial* or *Middle Palaeolithic* (named after Le Monstier, a station on the bank of the river Vézère in the Dordogne).—A period of ungenial climate (the Würm glaciation), during which man was obliged to seek shelter in caves, many of which have yielded remains of his handiwork. In addition, we have found numerous human bones from this period, and even a few complete skeletons. These enable us to restore a being of low stature (about 5 feet), with low forehead, great ridges in the skull over the eyes, a receding chin, undeveloped mentality, but powerful limbs. The flints show considerable degeneration as compared with the preceding period.

5. *Aurignacian* (named after Aurignac, Haute-Garonne).—A more genial climate. Europe was covered with herds of wild horses, upon which the hunters fed. Tools improved; beginning of an industry in bone. Above all, beginning of the pictorial art, which is one of the most remarkable manifestations of Palaeolithic activity. See ART.

6. *Solutrean* (named after Solutré, near Mâcon).—Especially characterised by extraordinary skill in chipping flint. The pictorial art for a time suffers eclipse.

7. *Magdalenian* (named from the cave of La Madeleine, Tursac, Dordogne).—In this period the bone industry and the pictorial art reach their high-water mark. The bone implements of this period consist of well-made needles, borers, harpoon-points, and a series of implements of unknown use, called by the French archaeologists *lâtons de commandement*. They are decorated with engraved figures, usually of animals; among them life-like representations of animals now either wholly or locally extinct (such as the mammoth and the reindeer) are to be recognised. They are drawn with wonderful faithfulness, freedom, and spirit. The cave-walls are also decorated with engraved and painted representations of animals and other devices. These last three stages constitute the *Upper Palaeolithic*.

The upper Palaeolithic culture must have been introduced into Europe by an invading race, in every way, physically and mentally, superior to the British Monsterials. Bones of the upper Palaeolithic peoples have been found in not inconsiderable numbers.

The Palaeolithic shades into the Neolithic by a series of approximations, the relationship between which is as yet very obscure. These fall

approximately in time into the period of the final oscillations of the disappearing Ice Age, which succeeded the great glaciations. The principal transitional stages are as follows:

The *Azilum*, so called from the cave known as Le Mas d'Azil in the Pyrenees; characterised by disappearance of the now extinct fauna, rather rude flint flakes, harpoons with flat shanks (not round shanks as in the Magdalenian harpoons), minute ('pygmy') flints, and pebbles decorated with painted lines, the last degeneration of the Palaeolithic art. The prototype of these pebbles, which probably had some magic-religious purpose, is to be sought in the *Capsian* art of Spain, an

Fig. 3. - Lozenge-shaped (a), leaf-shaped (b), and barbed (c) arrow-heads of Flint.

industry of North African origin, and contemporary with the Magdalenian of the south of France.

The *Asturian*, a recently isolated industry, of which some stations have been found in northern Spain, distinguished by a peculiar form of rudely pointed flint implements.

The *Campignian*, which first appears in southern Scandinavia, and is traced through the midden-heaps of the Danish coast into France (it bears its name from Le Campigny, one of the type stations in that country). The Campignian civilisation is the first that has been found in Ireland; the Azilian

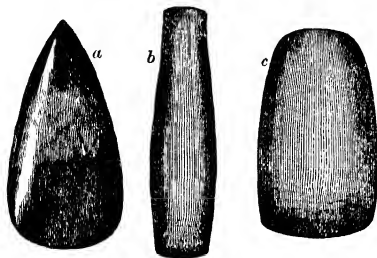

Fig. 4. - Polished Stone Axes or Celts: a, $5\frac{1}{2}$ inches; b, 13 inches; c, 5 inches long.

in Scotland. The lower Palaeolithic is found in the southern counties of England, the middle Palaeolithic about as far north as Derby.

The Neolithic period began with the final disappearance of the ice (the *Damm* oscillation, dated roughly about 7000 B.C.), and continued until it was superseded by the introduction of bronze, probably about 2500 B.C. The Neolithic inhabitants of Europe were not mere nomads; they were settled on the land, which they cultivated, and upon which they reared flocks and herds. They were able to venture upon the sea, as is shown by the presence of the bones of deep-sea fishes in their midden-heaps on the sea-coasts. They lived in huts made of earth or of stones, usually circular

in form—the excavation of the sites of these huts has given much information as to their mode of life—or else, in regions such as Switzerland, which have many lakes, upon platforms of wood supported on piles driven into the lake bottoms. They possessed all the animals now domesticated, with the exception of the cat. Their tools were chipped from flint, and show a considerable variety of specialised forms—a sure sign of advance in civilisation; and as remains in the lake dwellings show, they were equally expert in making implements of wood and of bone. The marvellous Danish daggers, which are the finest products of the flint-chippers' skill in Europe, are more probably to be assigned to the Bronze rather than to the Stone Age; the forms of these weapons appear to be suggested by bronze daggers. As was mentioned above, the polished stone axes and other implements that have been described as Neolithic cannot all be assigned to that period.

It is noteworthy that with this advance in the arts of life there went a complete extinction of the pictorial art so characteristic of the earlier period. On the other hand, there is to be seen evidence of a very highly developed social organisation. This is shown, *first*, by evidences of trade—the distribution of ornamental and precious stones far from their natural source of supply, and also of the peculiar Pressigny flints. This indicates the possibility of merchants travelling from tribe to tribe, which they could hardly have done unless there were some machinery to secure them a safe-conduct; *secondly*, by the enormous stone monuments which were erected in certain parts of Europe as burial places. These constructions are made of stones, some of which may weigh anything up to seventy tons, and could not have been manipulated at all except by a large body of men working together for a common purpose.

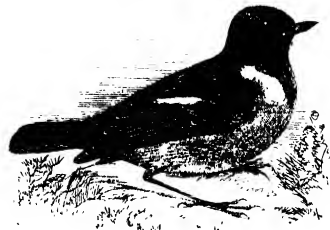

The method of burial in the Stone Age is most commonly by inhumation; cremation is not altogether unknown, but it is much more characteristic of the Bronze Age. The human remains show that already the population of Europe was an almost inextricable racial mixture.

See Déchelette's *Manuel d'archéologie*, vols. i., ii.; Sollas, *Ancient Hunters*; H. F. Osborn, *Men of the Old Stone Age*; J. M. Tyler, *The New Stone Age in Northern Europe*. For a short handbook on the subject, the *British Museum Guide to the Stone Age* may be recommended.

Stone-chat (*Saxicola rubicola*; see CHAT), one of the most common of the British Turdidae, a

Fig. 5. Danish Flint dagger.

Stone-chat (*Saxicola rubicola*).

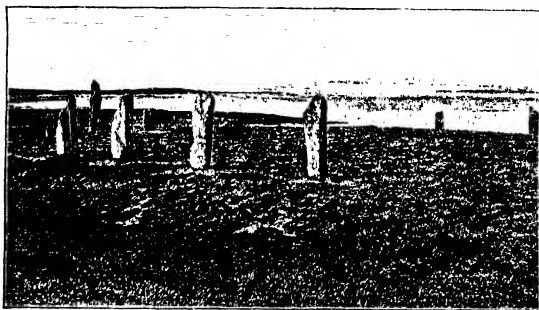

pretty little bird, rather smaller than the red-breast, black on the upper parts and throat in summer; the breast of a dark reddish colour; some

white on the sides of the neck, the wings, and the tail. It makes its nest of dry grass and moss, lined with bents, hair, and feathers, on the ground or at the foot of a low bush. It is a partial migrant in the British Isles; some migrate southwards in cold winters, and there is an influx of others from continental regions. It is somewhat local and erratic in its distribution, frequenting a place for a few seasons and then suddenly abandoning it. It feeds on insects, grubs, worms, and seeds. The name 'chat' is applied also to other members of the genus *Saxicola*, e.g. Whin-chat (q.v.).

Stone Circles, or Circles of Standing Stones (q.v.), popularly, but erroneously, called Druidical Circles in Britain, Dom-rings or Thing-steads in Scandinavia, and known as Cromlechs in France, consist of unhewn stones set up at intervals round the circumference of a circular area usually of level ground, though they are sometimes found on the slightly sloping side of a hill. The area thus marked off from the surrounding ground varies in size from less than 20 to more than 100 yards in diameter. The number of stones composing the circle also varies greatly, but as most stone circles exist now in a condition of greater or less dilapidation it is often impossible to ascertain with certainty what the original number may have been. Sometimes they are mere boulders rolled into position, at other times they are pillar-stones, evidently chosen for their length, and wedged upright by smaller stones inserted round their bases in the cavity in the subsoil prepared for their reception. Sometimes there is a single circle only, at other times one or two smaller circles are contained concentrically within the outer circle. At Callernish (q.v.) lines of stones radiate out from the circle. Occasionally the area on which the circle stands is further marked off from the surrounding ground by a trench, or by a trench and rampart of earth surrounding the whole, except where a narrow pathway gives access to the interior on the original level. In the district of Scotland between the Dee and the Spey there are numerous examples of a special variety of stone circle distinguished by the presence of a great flat block placed on edge so as to fill one of the intervals between two of the upright pillars, usually on the south-west side of the circle. Circles of small boulder stones placed close together and scarcely showing above the turf are also found in many parts

of Europe, indicating that the space thus enclosed has been reserved for burial deposits in prehistoric times. But the circles composed of large stones set at considerable intervals apart are linked with the burial customs of the builders of the chambered cairns of the Stone Age. A great circle of standing stones encircled the gigantic chambered cairn of New Grange in Ireland, and the smaller cairns of Clava in Strathnairn near Inverness are similarly encircled by pillar-stones. As a rule the cairns which covered the cremation internments of the Bronze Age are smaller than those of the preceding period, and the custom of placing the burnt bones in a cavity in the soil, covered only by an inverted urn of clay, dispensed with the cairn altogether, while it retained the circle of standing stones as a visible mark or fence of the grave-ground. In a number of instances in Scotland the examination of the interior space has disclosed burials of the Bronze Age, mostly after cremation, but occasionally unburnt. The

cremated remains were deposited with cinerary urns placed either in an inverted position over the burnt bones or upright and containing the burnt bones, at the bottom of a shallow pit excavated in the subsoil. These cinerary urns exhibit the forms and ornamentation characteristic of the age of bronze. Sometimes the burials have been placed in cists of unhewn slabs of stone, covered by small cairns of loose stones, underneath the surface level; at other times the burnt bones of many burials have been found placed in shallow cavities excavated in the soil of the interior area of the circle, near the bases of the upright stones. From these circumstances it is conclusively demonstrated that the common varieties of stone circles in Scotland are circular cemeteries of Bronze-Age burials. It may be that the greater circles, like those of Stennis, Avebury, and Stonehenge, may have had a different origin and purpose, but there is no evidence more conclusive than mere conjecture for the assumption of a different purpose for the larger circles, and the great size of the circle surrounding the immense chambered cairn of New Grange shows that a great circle was associated with sepulture.

Ring of Brogar, Stennis, Orkney, before restoration.

The original number of pillar-stones was probably sixty, of which only thirteen were standing before the Commissioners of Works took possession and had the others re-erected in 1908; ten were prostrate, and the stumps or fragments of thirteen more were still recognisable. The stones range up to 14 feet in height. The average distance between the stones is about 17 feet. A smaller circle, the Ring of Stennis, composed of larger stones, stands about a mile to the south. Its whole interior area is raised about 3 feet above the surrounding level, and has had a circumscribing ditch, with a rampart on the inner side. Only two stones were standing before 1908. A larger one, which was prostrate, is 19 feet long and 5 feet broad. It was near this circle that the perforated stone stood, through the aperture of which it was the custom in the 18th century for young men and women of the district to plight their troth by joining hands, a promise of marriage thus made being regarded with superstitious reverence as specially binding. The largest

stone circle in England is that of Avebury (q.v.) in Wiltshire. This monument is apparently alluded to in a charter of King Athelstan, dated 939 A.D., where one of the boundaries is said to run 'from the road to Hackpen northward, up along the Stone Row, thence to the burying-places.' Stonehenge (q.v.), the most famous of British stone circles, differs from other stone circles not only in its ground-plan, but in the pillar-stones of the exterior circle and the larger ellipse surmounted by imposts, mortised on tenons in the tops of the uprights, and also by the stones being at least partially tool-dressed. In Norway and Sweden stone circles have been found to be burial-places of the Iron Age. They are usually simple circles composed of eight to thirteen stones; occasionally there are two concentric circles, the inner circle being sometimes composed of small stones set close together in a ring. Sometimes there is a single pillar-stone in the centre of the circle. As a rule they are not remarkable either for the size of the circles themselves or for the massiveness of the stones of which they are composed. Circles of standing stones are widely distributed. In Algeria megalithic circular burial-places are not uncommon, but they do not correspond in general with those of northern Europe, being rarely composed of pillar-stones. Circles of pillar-stones, apparently of comparatively recent origin, have been found in northern India, and megalithic circles are stated to have been occasionally met with east of the Jordan, and in northern Arabia.

See Ferguson's *Ruile Stone Monuments* (Lond. 1872); Anderson's *Scotland in Pagan Times* (Edin. 1886); *Plans and Photographs of Stonehenge*, by Sir Henry James (1867); T. E. Peet, *Rough Stone Monuments* (1912).

Stone-coal. See ANTHRACITE.

Stone-crop. See SEDUM.

Stone-fly (*Pleco*), a genus of insects typical of the order Plecoptera. The hind-wings are broader than the fore-wings, and folded at the inner edge. The body is elongated, narrow, and flattened; the wings fold close to the body, which generally bears two terminal bristles. The larvae are aquatic, and much resemble the perfect insect, except in the absence of wings. A number of species—e.g. *P. brevidata*—are common in Britain, and are well known to anglers as an attractive lure for fishes.

Stone-fruit. See FRUIT.

Stoneham, a town of Massachusetts, 9 miles N. of Boston, with large boot and shoe factories. Pop. 8000.

Stonelhaven (locally *Stanchine*), a seaport and (since 1607) the county town of Kincardineshire, 16 miles SSW. of Aberdeen, is situated on a rocky bay at the mouth of Carron Water, which divides it into an Old and New Town. The harbour, formed since 1826, can admit only small vessels; but Stonelhaven has very considerable herring and haddock fisheries. It was constituted a police-borough in 1889. Pop. (1841) 3012; (1901) 4577; (1921) 4856. See DUNNOTAR.

Stonehenge, a circular group of gigantic standing stones on Salisbury Plain, about 2 miles from Amesbury in Wiltshire, situated in the midst of an extensive group of prehistoric barrows of the Bronze Age. The circle of stones, which is about 100 feet in diameter, occupies the central portion of an area of about 300 feet in diameter, enclosed within an earthen rampart and ditch. It consists of two concentric circles enclosing two horse-shoes, both open at the north-east end. The exterior circle, which is composed of pillar-stones of Tertiary sandstone, locally called 'gray-wethers' or 'sarsens,'

set up at pretty regular intervals of about 4 feet apart, has been surmounted by a continuous line of imposts closely fitted to each other at the extremities, and having mortise-holes in their under sides, which receive tenons on the tops of the pillar-stones. The pillar-stones show generally about 13 feet of height above the ground, and the imposts are about 10 feet long, 34 feet wide, and 2 feet 8 inches deep. Of this circle sixteen pillar-stones and five imposts retain their original position. These stones were found lying about the plain, the remains of a cap of sandstone that had almost vanished. They were transported ready-dressed. About 9 feet within the exterior circle are the remains of a second circle of smaller blocks of rock, locally known as 'blue stones.' They are irregular in shape and height, and do not seem to have supported imposts, but few now remain standing, and their number and respective positions cannot be accurately determined. It seems to be ascertained that these stones (dolerites and rhyolites) must have been brought from Pembrokeshire, and dressed at Stonehenge. Within this inner circle, and separated from it by about the same distance, is an incomplete ellipse, nearly of horse-shoe form, with the open end facing the north-east, formed of five trilithons or groups of two immense pillar-stones supporting an impost. The central trilithon facing the open end of the ellipse was the largest, the pillar-stones being about 23 feet in height above ground, and the added height of the impost making the whole height of the trilithon nearly 28 feet. The other four, which stood facing each other, two and two on opposite sides of the ellipse, are somewhat smaller. Only two of the five are now perfect; the central one wants the impost, which fell in 1620, one of the pillars lies broken on the great stone, popularly called 'the altar stone'; the other, which leaned over, supported by one of the smaller stones in front of it, was set upright in 1901. Of the two trilithons on the west side of the ellipse, the one next the open end has only one pillar-stone standing, the other has fallen inwards with the impost, and both are broken; the other trilithon fell outwards in 1797, but the three stones, though prostrate, are still entire. The trilithons of the ellipse are of the same Tertiary sandstone as the pillar stones and imposts of the exterior circle. They are partially tool-dressed. Within this ellipse is a smaller ellipse of the same form, but composed, like the second circle, of irregularly-shaped 'blue-stones' without imposts, varying from 6 to 8 feet in height, and set at intervals of about 5 to 6 feet. Within the whole, backed by the great trilithon, lies the so-called altar-stone of micaceous sandstone, supposed like the 'blue-stones' to come from Pembrokeshire. Outside the circle, but within the earthwork, are two unworked sarsens, to north-west and south-east, while to north-east stands a third, the Friar's Heel, outside the earthwork, on the axis of the whole. In line with it on the edge of the ditch lies a stone fancifully named 'the slaughter-stone.' From Stonehenge a straight earthwork or avenue runs for a quarter of a mile.

On 31st December 1900 one of the stones of the outer circle was blown down; and the proprietor, Sir E. Antrabus, in concert with several archaeological societies, had the whole enclosed, and the question of preservation and restoration placed in the hands of engineering experts. The Office of Works and the Society of Antiquaries undertook the securing of stones that were in danger. Stonehenge was sold in 1915 to Mr C. H. E. Chubb, who gave it to the nation in 1918.

Stonehenge is first chronicled by Henry of Huntingdon in the 12th century as one of the four wonders of England. Geoffrey of Monmouth says it was erected by Aurelius Ambrosius, in com-

memoration of the British nobles slain by Hengist; that Aurelius himself was buried in it; and that Constantine, in the 6th century, was buried 'close by Uther Pendragon, within the structure of stones which was set up with wonderful art not far from Salisbury, and called in the English tongue Stonehenge.' Camden copied a drawing of it, which shows its outer circle much more complete than at present. Inigo Jones, in 1620, laments the disappearance of stones that were standing when he measured it. Stukely deplors the loss of the fallen stones carried away to make bridges, mill-dams, and the like. Aubrey mentions a large stone carried away within his remembrance to make a bridge. His plan shows a number of depressions

(1895), Lady Antrobus (1901), Sir N. Lockyer (1906), E. H. Stone (1924); a small guide by F. Stevens (revised 1924); and *The Antiquaries' Journal* (1924).

Stonehenge, the pseudonym of JOHN HENRY WALSH (1810-88), a native of Hackney, a surgeon at Worcester, and from 1857 editor of *The Field*, author and editor of works on dogs and sport.

Stonehouse, EAST, is now part of Plymouth (q.v.).

Stone River. See MURFREESBOROUGH.

Stones, PRECIOUS, is a vague term, as certain substances take rank in the list and disappear with the fluctuations of fashion; and the same name is often given to several substances which may have a superficial similarity, although they really belong to distinct mineral species. Further, in point of beauty and rarity, the mineral substances used for ornament so merge into the common and abundant that there is no possible dividing line between precious and common stones. Among the substances used ornamentally, however, there are a few which from all times have occupied a foremost place and have been universally prized as precious stones. In such a rank and position may be placed the diamond, the ruby, the sapphire, the oriental amethyst, and the emerald. These, on account of their rare properties - their lustre, their play of light, their brilliance of colour, their great hardness and consequent durability, and especially be-

Stonehenge.

(Reproduced by permission of the Controller of H.M. Stationery Office, from *Stonehenge To-day and Yesterday*, by F. Stevens.)

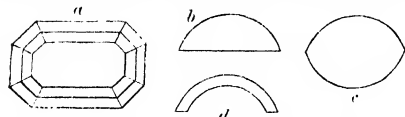

within the circular earthwork. These have been located by Col. Hawley and Mr Newall, who found two rings of holes in the chalk, many of them containing charred human and other bones. These holes (with some exceptions) seem to have held stones, which had been removed before they were turned to use for burials. Various excavations at Stonehenge have brought to light flint flakes, stone hammers and mauls, chips from the dressed stones, fragments of rude pottery similar to the urns found in the neighbouring barrows, bones of oxen and portions of stags' horns used as picks to make holes in the chalk to receive the stones. The only evidence that the builders of Stonehenge knew the use of metals is a small stain of carbonate of copper on one of the stones. The inference has been drawn that the monument dates from very late in the Neolithic or the beginning of the Bronze Age, perhaps about 1700 B.C. Most archaeologists look upon it as an exceptional development from the ordinary type of Stone Circles (q.v.), used as burial-places by the late Stone and early Bronze Age people of Britain, though some regard its exceptional development as due rather to a religious influence than to the mere idea of the common commemoration of simple burial. Many seek an astronomical meaning. At the summer solstice an observer within the monument would see the sun rise very nearly in line with the slaughter-stone and the Friar's Heel. The other undressed stones might mark the position of sunset at the summer solstice and sunrise at the winter solstice. But these directions are only approximate; and to get a plausible date it is necessary to abandon them for an arbitrary line. Sir Norman Lockyer used Silbury Hill. Whatever its origin, it is the grandest megalithic monument in Britain. See books by Long (1876), Gidley (1877), E. Barclay

cause of their extreme rarity, have always been the most esteemed of jewel stones. In the second rank, as well-established precious stones of minor value, may be included the spinel or balas ruby, the Brazilian topaz (the oriental topaz is a yellow sapphire), the varieties of garnet, the turquoise, the tourmaline, the aquamarine or pale emerald, the chrysoberyl or cat's eye, the zircon or jargon, the opal, and the varieties of quartz, such as rock-crystal, agate, amethyst, cairngorm or Scotch topaz, chalcedony, jasper, onyx, sardonyx, &c. Among other beautiful and valuable stones much appreciated for ornamental purposes, but scarcely to be classed as precious stones, there may be included lapis lazuli, crocidolite, labradorite, moonstone, aventurine, and malachite. To the list of precious stones there should be added two substances of animal origin—pearls and red coral—and perhaps also amber, a comparatively rare and valuable fossil resin. The various substances here enumerated are dealt with, for the most part, under their own proper names.

For the development of the sparkle, lustre, and glow of colour of most precious stones it is essential that they should undergo the process of cutting and polishing. When lustre and sparkle are the principal qualities to be revealed, as in the case of the diamond, the surface is most favourably cut into numerous plane facets as either brilliant or rose cut stones (see DIAMOND, figs. 1 and 3). When colour is the more important quality of the stone it may, if plane surfaces are wanted, be step or table cut (*a* in fig.). Such stones also, and translucent and opaque stones, may be cut *en cabochon*—i.e. with curved or rounded surfaces. The varieties of cabochon cutting are single cabochon (*b*), or high plano-convex double cabochon (*c*), and double convex and hollow cabochon (*d*).

the latter being much used for large garnets, which so cut are called carbuncles.

One of the most important qualities of a precious stone is its hardness, as upon that properly depends

its power of resisting wear and of keeping the brilliancy of its polished surface. It is a property of great constancy, moreover, and in many cases affords a ready means of determining the nature of a stone under examination. Of all known substances diamond is the hardest, and representing it, according to Mohs's scale, by 10, the following is the relative hardness of several of the more important of the precious stones: Diamond, 10.0; sapphire, 9.0; ruby, 8.8; chrysoberyl, 8.5; spinel, 8.0; topaz, 8.0; aquamarine, 8.0; emerald, 7.8; zircon, 7.8; tourmaline, 7.5; amethyst, 7.0; moonstone, 6.3; turquoise, 6.0; opal, 6.0.

Artificial Precious Stones.—Numerous attempts have been made by eminent investigators to produce artificial precious stones by means of intense heat and pressure and by electrical action; but hitherto these efforts have failed of practical success. In an important memoir published by Sainte Claire Deville and Caron in 1858 (*Comptes Rendus*, vol. xlv.) they describe the various processes by which they obtained small crystals of corundum, ruby, sapphire, &c. By the action of the vapours of fluoride of aluminium and boric acid on one another, they obtained crystals which, in hardness and in optical properties, resembled natural corundum. When a little fluoride of chromium was added a similar process yielded violet-red rubies; with rather more fluoride of chromium blue sapphires were yielded; and with still more green corundum was obtained. A mixture of equal equivalents of the fluorides of aluminium and glucinum, when similarly acted on by boric acid, yielded minute crystals of chrysoberyl. The action of fluoride of silicon on zirconia yields small crystals of zircon, and by the action of silica on a mixture of the fluorides of aluminium and glucinum hexagonal plates of extreme hardness were obtained, which in some respects resembled emerald.

In subsequent researches Becquerel (*Comptes Rendus*, vol. lviii.), by the use of electric currents of high tension, succeeded in obtaining opals, &c. from solutions of silicates. Among the most successful of experimenters in this direction was the chemist Charles Feil of Paris, who successfully crystallised alumina, and by the introduction of colouring matter produced sapphires and rubies identical in hardness and composition, but not in brilliancy, with the natural stones. Feil also succeeded in preparing true crystals of spinel, and a blue fine spinel of great hardness, but glassy rather than crystalline in structure.

Imitations of precious stones consist of a soft, heavy flint-glass called strass or paste, appropriately coloured, and they may readily be distinguished, among other peculiarities, by their great softness. Fraudulent combinations are made by cementing thin plates of precious materials over, and sometimes also under, a body of valueless glass, and thus the exposed surface or surfaces when tested are real stones, and the venerated mass passes as a large and valuable possession.

Stoneworts. See CHARA.

Stonyhurst, a great Roman Catholic college in north-east Lancashire, 4 miles S.W. of Clitheroe, traces its origin to the seminary at St Omer (q.v.) in France, which was founded in 1592 by Father Parsons (q.v.). The seminary ere long had 200 students, but after many vicissitudes was suppressed by the tyranny of the Bourbons in 1762. After a short sojourn at Bruges till 1772, and at Liège till 1794 (when the French revolutionary armies were closing round it), the eighteen Jesuit fathers were offered a resting-place at Stonyhurst by Mr Weld of Lulworth, an old alumnus, to whose family the old home of the Shireburnes had in 1754 passed by marriage. The fine house, begun about 1594, was beginning to fall into ruin, and even when restored provided but scant accommodation for the 200 students who soon flocked to it. Extensions were made in 1810–78, the chapel being built in 1835, and other additions have since been made. The numbers have gone on increasing with some fluctuations, and are now about 400, including students of university standard and the younger boys of the preparatory school at Hodder, a mile distant. Games are much encouraged, and special forms of football and handball seem to have been brought from St Omer. The library has many valuable MSS. and early printed books; and the college possesses a collection of pictures, a museum of antiquities, scientific collections, and fine specimens of embroidery and church-plate in the sacristy (many of these treasures having been preserved from St Omer days). The college observatory rose into note under Father Perry, F.R.S. Many of the institutions—the names of classes, exercises, holidays—date from the residence abroad.

See Hewitson, *Stonyhurst College* (Preston, 1870; 2d ed. 1878); *Memoirs of Stonyhurst College* (1881); Father Gerard, *Stonyhurst College* (Ato, 1894); Guggen and Keating, *History of Stonyhurst* (1901).

Stony Stratford, a market-town of Bucks, on Watling Street and the Ouse, 8 miles N.E. of Buckingham. It had an Eleanor cross till 1646, and suffered from fire in 1742.

Stool of Repentance, facetiously called 'Cutty-stool' (normally a domestic wooden stool with short legs), represented in post-Reformation Scottish churches part of the old discipline of Penance (q.v.). The place of repentance was sometimes a stool or bench, sometimes a pew or part of the gallery, sometimes a special erection as high as the gallery, containing several seats or stances, and ascended by stairs. Whatever it was and whatever called, it was about the most conspicuous thing in the church; and here persons who had become subject to ecclesiastical discipline for immoral conduct were required by the kirk-session to stand during public worship in profession of their penitence. The penitent was usually bare-headed and bare-footed, clothed in sackcloth or a linen sheet (kept for the purpose by the kirk-session); the ceremony might or might not be concluded by a public rebuke from the minister. For minor offences one appearance in the place of penitence might suffice; for the sin of fornication three several Sundays' penitence were usually inflicted; a much larger number of days was not at all unusual; and some offences (such as incest) might imply fifty-two Sabbaths in the place of penance unless the culprit were condemned by the civil courts to capital punishment. The stool of repentance was steadily maintained during great part of the 18th century, but gradually fell into desuetude, its place being taken by public rebuke before the congregation (still enforced in some places to near the middle of the 19th century), and afterwards by rebuke administered in presence of the session only. See Dr Edgar on 'Discipline' in *The Church of Scotland*, vol. v. (1891).

Storax, a resin resembling benzoin, was in high esteem from the time of Pliny to the end of the 18th century. It was obtained from the stem of *Styrax officinalis*, a native of Greece and the Levant, but owing to the destruction of the trees it has now disappeared from commerce. It was used as a stimulating expectorant.—**LIQUID STORAX**, a soft viscid resin, opaque and gray brown, heavier than water, is obtained from the *Liquidambar orientale*, a tree 40 feet high, forming forests in the south-west of Asia Minor. It has a balsamic odour and a pungent burning aromatic taste. It contains from 6 to 20 per cent. of cinnamic acid, besides a hydrocarbon, *Styrol*, a volatile oil, and various fragrant ethers. It is used but seldom in medicine, but has a reputation in chronic bronchial affections. Externally it has been employed in scabies.

Stork, a group of birds characterised by having the bill larger than the head, very stout at base, not grooved, tapering to the straight recurved or decurved tip; nostrils pierced directly in the horny substance, without nasal scale or membrane, high up in the bill, close to its base; legs long, and with reticulate scaling; three toes, with sometimes a rudimentary fourth, the claws not acute. The storks are usually divided into the True Storks and the American 'Wood Ibises' (*Tantalus*). There are several genera of storks, including about a dozen species. They belong chiefly to the Old World. The most familiar representative of the family is the Common Stork or White Stork (*Ciconia alba*), a native of the greater part of the Old World, a migratory bird, its range extending even to the northern parts of Scandinavia. It is common in many parts of continental Europe (though not in France, Italy, or Russia), but is especially familiar in Holland and North Germany, the storks arriving annually in February and March, and in autumn returning to Africa in large flocks, flying mostly by night. It is about three feet and a half in length. The head, neck, and whole body are pure white; the wings partly black; the bill and legs red. The neck is long, and generally carried in an arched form; the feathers of the breast

backward on the shoulder. It frequents marshy places, feeding on eels and other fishes, frogs, lizards, snakes, slugs, young birds, small mammals, and insects. It makes a rude nest of sticks, reeds, &c. on the tops of tall trees, or of ruins, spires, or houses. There are four or five eggs, white tinged with buff; and the old nest is re-occupied next year. In many parts of Europe, especially in Holland, it is a very common practice to place boxes on the roof for storks, and children are told that storks bring the babies. Storks are protected by law in some countries, on account of their good services not only in destroying reptiles and other troublesome animals, but in the removal of offal from the streets of towns, in which they stalk about with perfect confidence, even in the midst of throngs of people. They have been celebrated from ancient times for the affection which they display towards their young, and have also had the reputation—not so well founded—of showing great regard to their aged parents. Before they take their departure from their summer haunts they congregate in large flocks, which make a great noise by the clattering of their mandibles, and are popularly regarded as holding consultation. The stork has no voice. It is a very rare bird in Britain, and was so even when the fens of England were undrained. Bower says that in 1416 storks came and built their nests on the roof of St Giles' Church in Edinburgh; there they remained a year and departed to return no more; 'and whither they flew,' adds the chronicler, 'no man knoweth.' The flesh of the stork is rank and not fit for food. The Umbrette (*Scopus umbretta*), an African and Madagascar bird, remarkable for the enormous domed nest which it builds, is nearly allied to the storks and seems to be a link connecting them with the herons. The Balaniceps (q.v.) or Shoe-bill is also a stork, with affinities to the herons.—For the migration of storks, see *Nature*, December 1910, p. 203.

Storm, THEODOR WOLDSSEN (1817-88), German poet and story-writer, was born at Husum in Sleswick, and spent most of his life (1842-80) as magistrate and judge in the service of Sleswick-Holstein and Prussia. His poetic reputation rests upon his *Gedichte* (1852). Of his stories, mostly short, the best are *Immensee* (1852), a poetic idyll in prose; *Zerstreute Kapitel* (1873); *Aquis Submersus* (1877); *Psyche* (1877); *Carsten Curator* (1878); *Hans und Heinz Kirch* (1883); *John Riew* (1886); and *Der Schimmelreiter* (1888). The charm of these little tales lies in the poetic and idyllic atmosphere in which the action is placed, the unobtrusive skill with which they are told, and their deep feeling. See *Lives of Storm* by Schintze (1911) and Gertrud Storm (1912 et seq.).

Stormontfield. See PISCICULTURE.

Storms. The term storm is most frequently used to denote a very high wind or gale; but it is not strictly confined to wind, and its use to denote any intense meteorological phenomenon still survives in snowstorm, thunderstorm, hailstorm, while an integral part of a storm at sea is the turbulence of the waves.

The following special phenomena will be treated in this article: (1) Storms of temperate latitudes, arising generally from cyclones or depressions; (2) line squalls; (3) tornadoes; (4) tropical revolving storms and the associated hurricanes; typhoons; (5) thunderstorms; (6) sandstorms and haboobs, scirocco, Bora, Mistral, Simoom, Sumatras.

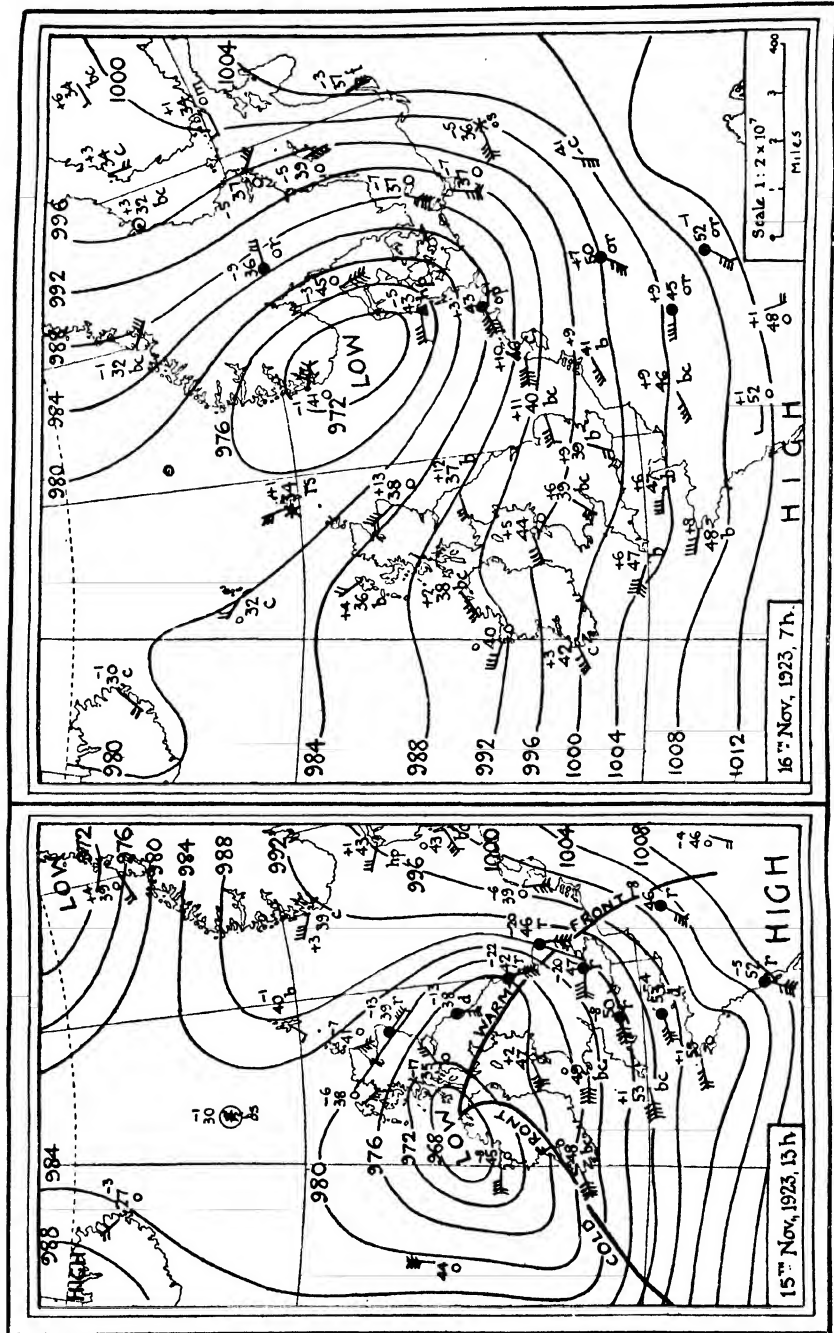

In Section 7 the character of the wind in a storm is described and a brief account of historic storms and of storm warnings is given.

1. STORMS OF TEMPERATE LATITUDES.—An

Common Stork (*Ciconia alba*).

are long and pendulous, and the bird often has its bill half hidden among them. The flight is very powerful and high in the air; the gait slow and measured. In flight the head is thrown back and the legs extended. The stork sleeps standing on one leg, with the neck folded, and the head turned

essential preliminary to understanding the way in which storms arise, progress, and die out is an account of weather maps. At a large number of places in different countries observations are made two, three, or four times a day of the barometer, temperature, wind, and weather. These observations are plotted according to certain simple conventions on an outline chart. When this is done, it is seen that the different observations are not a random spasmodic selection but fit together in a more or less systematic manner. Two such charts, called synoptic charts, are shown in figs. 1 and 2. They represent conditions over the British Isles and Western Europe on 15th and 16th November 1923. The continuous lines are isobars; along these lines the pressure of the atmosphere at sea level is everywhere the same; in other words, if barometers were placed along one of these lines at places at sea level they would all read exactly alike. The isobars are drawn for every 4 millibars (1 millibar = 1000 dynes per cm²; 1000 millibars = 29.53 in.). The arrows at the different places show the direction in which the wind is blowing, and the number of fleches on each arrow indicates approximately the speed at which the wind is blowing, according to the numbers of the Beaufort scale of wind force (No. 8 is a gale; see WIND). The figures alongside the arrows give the temperature of the air in degrees F., and the letters beneath show the character of the weather according to Beaufort's notation. The small figures above the temperature figures denote the rate at which the barometer is rising (+) or falling (-). The first map of this kind—constructed a long time after the actual date from observations collected in various publications—was made by Brandes for 6th March 1783, but the regular construction of synoptic charts did not begin until after 1860, when a scheme for the international exchange of telegraphic reports was introduced. This continued until after the war of 1914-18. In 1919 the exchange of reports by wireless telegraphy commenced, and now every country in Europe collects reports from its own stations, assembles them into a single report, and issues this collective report by wireless telegraphy, according to a time-table fixed internationally in such a way that the majority of the reports have been transmitted within 1½ hours of the time of observation, and practically all of them within 2½ hours.

The original idea underlying the collection of observations and the construction of charts was that storms travelled, and if their existence could be ascertained and their track deduced it would be a simple matter to give warning of them; in fact, the final impulse which launched the international scheme came from a travelling storm. On 14th November 1854 a storm burst suddenly upon the British and French fleets in the Black Sea and did much damage, wrecking one French battleship. The French astronomer Leverrier collected evidence of the storm's progress across Europe, and proved that its arrival in the Black Sea could have been foreseen had telegraphic weather reports been collected at a central office.

The earliest studies of synoptic charts revealed two outstanding features—cyclones, or regions of low barometer; and anticyclones, or regions of high barometer. The first were generally associated with windy and wet weather, and the second with quiet dry weather. An examination of the distribution of wind and weather in cyclones was made by Abercromby in 1880-85. Two of his conclusions are: 'there is no difference between ordinary weather and a storm except in that property called intensity,' and 'in forecasting storms we have not only to foresee the arrival of a cyclone, but of one possessing sufficient intensity to cause a gale; and

in tracking a gale it by no means follows that the same one (cyclone) causes a storm during every day of its existence. For instance, on 14th August 1873 a cyclone was formed a little west of the Cape Verde Islands, which passed as a hurricane round Bermuda to Newfoundland by the 27th, after which it crossed the Atlantic and Great Britain as an ordinary cyclone, till it died out in Norway on 2d September and gave rise to nothing more than moderate breezes.' It was also found that deformation of a cyclone might occur, and that a bulge of the isobars, usually at the southern extremity of the cyclone, might have the features of wind and weather appropriate to a cyclonic entity; and that the bulge sometimes developed into a definite new cyclone with closed isobars. Such bulges and their developments were called 'secondaries.' An explanation of their origin will be given below. The existence and development of these secondaries, and the variations both in the intensity of cyclones and in the distribution of wind and weather over the area of a cyclone make it impossible to achieve successful forecasts on the assumption that weather merely 'travels.' Account must be taken of 'development.' One of the most useful practical aids both for travel and for development is 'barometric tendency.' This is a numerical index of the rate of change of pressure per three hours, and it is combined with an index of the character of the change, e.g. rising steadily, rising then falling, steadily then falling. It is indicated on the charts for 15th November 1923, and it will be noted that the centre of the cyclone moves towards the region of greatest negative tendency. A cyclone with negative tendencies all round it is growing deeper and more intense; a cyclone with positive tendencies all round it is growing less deep—it is, in fact, a dying cyclone.

Mention has been made of the isobars or lines of equal pressure. The speed of the wind in cyclonic storms of temperate latitudes is determined by the distance apart of the isobars; even if no observations of wind were available but only observations of pressure, the meteorologist could tell with great accuracy what the actual winds would be. For isobars with little curvature, the speed of the wind at a height of 1000 to 1500 feet can be computed from the equation:

$\Delta p = \Delta n \cdot d \cdot 2\pi v \sin \lambda \dots (1)$ where Δp = difference of pressure between consecutive isobars; Δn = distance between consecutive isobars; d = density of air; v = angular velocity of the earth's rotation; V = speed of wind (gradient wind); λ = latitude.

For latitudes between 50° and 55° and isobars differing by 4 millibars as those in fig. 1 the distance between the isobars for a wind of 100 miles per hour is approximately 40 miles. The direction of this wind, V , is along the isobars, and it blows so that a person facing it would have the lower pressure on his right hand in the northern hemisphere and on his left hand in the southern hemisphere.

The wind at a height of 30 or 40 feet over the open sea, or over level country free from obstructions like trees or houses, is usually about two-thirds of the gradient wind, but the actual value of the ratio over land depends upon the time of day; it increases in the middle of day and decreases at night. The wind at the surface is also inclined at an angle to the direction of the isobars, and therefore to the wind, V .

The relation expressed in the equation (1) is based on the hypothesis that the force on the moving air, which arises from the effect of the earth's rotation (the geostrophic force), is balanced by the pressure gradient. Hence the wind derived from the equation is called either the gradient wind or the geostrophic wind.

If the isobars are curved and stationary another

term, $\Delta n.d.V^2 \div r$, has to be added to the right-hand side of the equation if the curvature is cyclonic, and subtracted from it if the curvature is anti-cyclonic (r is the radius of the curved isobars). As the results of actual observation are in agreement with the winds derived from this equation, it will be readily realised how fundamental are charts of isobars in connection with storms of temperate latitudes.

Broadly speaking, storms arise through the juxtaposition of masses of air whose temperatures in the same horizontal plane are markedly different, and generally they are purely local and of short duration unless the masses of air are moving with different speeds or in different directions.

The cyclones of temperate latitudes are now considered usually to arise between masses of air of different temperature and different velocity. Over the polar regions there is a large section of the atmosphere which is colder not only at the surface of the earth but also up to heights of 20,000 or 30,000 feet, than the air of latitudes $30^\circ - 45^\circ$. The surface separating these masses of air slopes upwards towards the poles much as if the polar air were a heavy liquid running forward under a lighter one. The line in which the surface of separation meets the surface of the earth is called the Polar Front—north of this line (or south in the southern hemisphere) the air near the earth's surface is of polar origin, south of it the air is of tropical origin. Cyclones originate at the surface of separation. According to V. Bjerknes they are due to the surface taking a wave form; and as the waves are propagated along the surface, so the cyclones move, generally west to east. According to Erner of Vienna, cyclones are formed by a tongue of the polar air stretching out into the relatively warm current and damming it up so that a whirl is formed and moves forward dragging the cold air with it.

Such masses of air at markedly different temperatures, like those over the polar and equatorial regions, could not remain at rest in equilibrium; if they were at rest at sea-level, the sea-level pressure of the atmosphere would be everywhere the same; but then at a height of 10,000 feet over the regions where the temperature was 80° F . the pressure would be some 30 millibars (nearly one inch of mercury) greater than the pressure at that height over regions where the temperature was 30° F . This difference of pressure would break down the equilibrium state, and, broadly speaking, cold surface air would move from the polar regions towards the equator, and, at greater heights in the atmosphere, air would move from the equator towards the poles.

This essential fact—interchange of air between the polar and equatorial regions—is fundamental; the cyclones of temperate latitudes constitute the mechanism by which the interchange is effected across the temperate zone. Nowhere the equator the interchange can be made by broad general currents towards the equator at the surface (the trade winds) and by broad general currents from the equator at higher levels (the anti-trade winds); but no such straightforward scheme can persist in temperate latitudes, because the earth is a sphere and is rotating; the interchange takes rather the character of mixing, and the most effective mixing

agent in a fluid is a series of whirls. The whirls in this great mixing region of the atmosphere may be more than a thousand miles in diameter, and four or five of them sometimes encircle the earth in the higher temperate latitudes.

The manner in which cyclones of temperate latitudes develop is briefly as follows: the warm

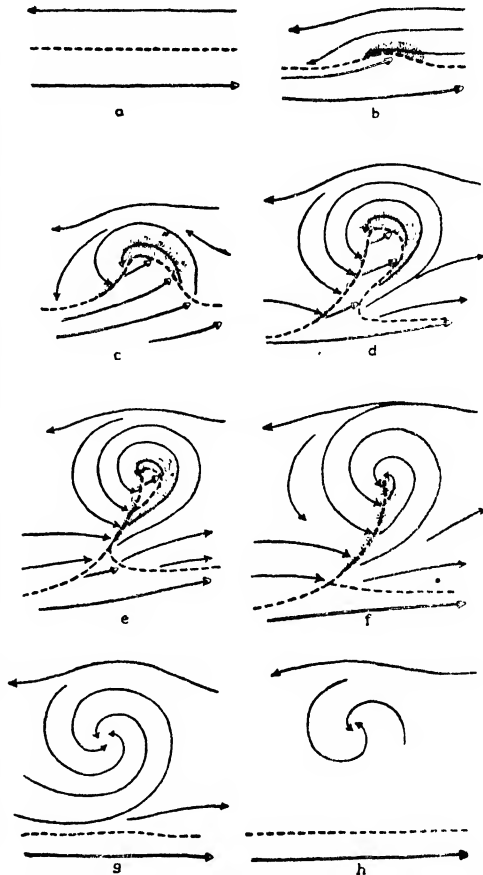

Fig. 3. —Life Cycle of a Cyclone (after Bjerknes and Solberg).
(Reproduced by permission of the Royal Society.)

air of lower temperate latitudes having in general come from nearer the equator has on the whole a motion from west to east; it retains, partially at least, the angular momentum about the earth's axis which it got in the neighbourhood of the equator. The cold air of higher temperate latitudes having in general come from nearer the pole has on the whole a motion from east to west; it retains similarly the smaller angular momentum about the earth's axis which it had when nearer the pole. In the temperate zone there is, therefore, in the north, cold air moving from eastwards, and, in the south, warm air moving from westwards. This state of affairs is represented schematically in fig. 3 (a) (due to Bjerknes and Solberg). This shows only conditions at the surface of the

earth; the division between the two currents is not a vertical plane but a sloping surface rising upwards towards the north; so that the warm air is moving over the top of the cold air. The slope of the surface is in actual cases small—it may rise only one mile in 200 miles or even less. Two such currents cannot go on running steadily alongside one another; the irregularities in the surface of the earth would produce irregularities in the surface of separation of the currents; and, apart from that, waves would form, as they always form, at the surface of separation of two fluids of different density. Fig. 3 (*b*) shows, therefore, a second stage in the development: the warm air begins to move northwards over the cold air, and the cold air to move southwards beneath the warm air at some place or other. Once the development has begun it tends to go on, and fig. 3 (*c*) shows the motion, become now cyclonic. In fig. 3 (*d*) the cold air, which tends to lag behind in the front part of the cyclone and to catch up in the rear part, has nearly cut off a section of the warm current, and in fig. 3 (*e*) it has achieved this; while in fig. 3 (*f*) the small patch of warm air has entirely disappeared.

So long as there is warm air in the cyclone every development results in more potential energy being converted into kinetic energy; the cold air rushes under the warm air with increasing intensity and the cyclone keeps growing deeper; but when all the warm air has been lifted up, the available potential energy (though it still exists at first in the stages 3 (*e*) and 3 (*f*)) when the cold air is still lifting higher the warm air over the line of separation) soon disappears and the cyclone gradually dies. When the warm air has been lifted from the surface the cyclone is said to be *occluded*, and the line where the cold air from the rear meets the cold air in front is called an *occlusion*: consideration of what happens at this line will be renewed later.

It is now necessary to consider what is happening in the cyclone during the development described. Fig. 4 will assist. The middle diagram indicates the motion of the air about the centre, and the shaded areas show the region in which rain (or snow) falls as a rule during the development; the rain in the wider strip along the warm front is usually continuous rain of moderate intensity, though it may be heavy; the rain in the narrower strip behind the cold front is usually in the form of showers, sometimes very heavy showers with hail and thunder. The upper diagram is a vertical section through the cyclone to the left of the path of the centre (right in the southern hemisphere); it shows the dividing surface between the cold air and the warm air, with the warm air above still streaming from west to east, though the cold air beneath is moving from east to west; there is a mass of cloud spread along this surface, and in the middle it is thick and dense enough to produce steady rain.

The lower diagram is a vertical section through the cyclone to the right of the path of the centre (left in the southern hemisphere) where the surface of separation comes right down to the ground. The slope of the surface is gradual over the cold air in front, and here the mass of cloud, thick and dense near the point where the surface meets the ground, spreads away perhaps for hundreds of miles until it is no more than a thin veil of cirro-stratus, causing haloes around the sun or moon. In the rear where the cold air is undercutting the warm air the slope of the surface is steeper, and there is a narrow but dense band of cloud, towering to great heights, and spreading forward a little over the warm air. In this illustration

there is no cloud or rain over the regions where the warm air is at the surface; but in some cases where the cyclone is growing rapidly deeper, the whole of this warm air is being forced upwards and cloud and rain extend also over the warm sector or a part of it.

If a barogram were taken at a place corresponding with the upper diagram of fig. 4 it would show

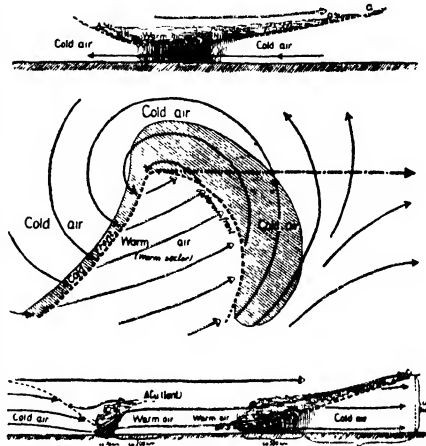

Fig. 4.—Constitution of a Cyclone (after Bjerknes and Solberg).

(Reproduced by permission of the Royal Society.)

a gradually falling barometer, followed by a gradually rising barometer: the wind also would change gradually from SE. or E. to NE. A barogram at a place corresponding with the lower diagram would be quite different: it would show a comparatively rapid fall, ceasing rather suddenly, and then a nearly steady barometer, perhaps rising slightly and then falling again slightly; suddenly there would be a sharp change in the curve and it would show a rather rapidly rising barometer.

Some of the most intense storms of temperate latitudes are caused by 'secondary' depressions: these are whirls in the general current moving round a primary cyclone; they are formed usually on the southern side of a primary (northern side in the southern hemisphere); the severest winds are on the side of the secondary, remote from the primary centre. The reason for this may be understood from the following illustration. Suppose a wheel 4 feet in circumference has an axis near its rim on which is a smaller wheel 2 feet in circumference, as in the diagram.

ACB is the large wheel, DEF the small wheel. Suppose the large wheel is turning on its axis, O, 5 times per second, and the small wheel is turning on its axis, C (which is itself moving round O), 10 times per second, both in the directions shown by the arrows. Then C will be moving at 20 feet per second, E will be moving at 40 feet per second, and G will be instantaneously at rest. Similarly, the wind in a secondary cyclone is the result of the secondary circulation superposed on the primary circulation.

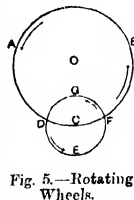

Fig. 5.—Rotating Wheels.

The method of formation of a secondary cyclone

is illustrated in fig. 6. The primary cyclone having become occluded, the cold air in front of the line of discontinuity cannot move away quickly enough, and is either actually moving westwards or is moving westwards relative to the current of warm air. This produces a condition similar to fig. 3 (b), and a new cyclone begins to develop while the rotation about the centre of the old cyclone is still going on.

Mention has been made of an occlusion, the line

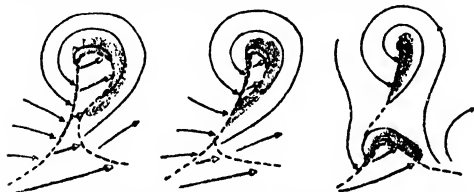

Fig. 6.—Formation of Secondary (after Bjerknes and Solberg).

(Reprinted by permission of the Royal Society)

along which the two masses of cold air in front of and behind a cyclone meet. As the different processes illustrated in fig. 3 take time, and simultaneously the cyclone is moving at perhaps 30 miles per hour, the two masses of cold air which meet at the occlusion will not be of identical constitution or temperature. If the air in the rear is colder than the air in front, the occlusion becomes a secondary cold front and the air in front is gradually lifted up as the colder air advances beneath it. Such a front is preceded by Cirro-Stratus clouds, whereas the ordinary cold front is preceded by Alto-Cumulus clouds. If the air in front is colder than the air in the rear, the latter begins to rise over the colder air and a secondary warm front results; the rain from such a warm front is usually slight, because there is not much moisture in the cold air. In very large cyclones, however, there may be considerable rain accompanying occlusions; and the potential energy, which is being converted into kinetic energy, is sufficient to maintain the cyclonic circulation for several days. Thus, although most of the cyclones which reach western Europe from the Atlantic are occluded before their arrival, they do not die rapidly, as they would if there were no discontinuity beyond the two fundamental ones of the primary cyclone.

It remains to add that the discontinuities in the cyclone are not always revealed by the surface temperature: the latter is frequently affected so much by the ocean or the land over which it passes that it is no good index of the temperature of the mass of air. It is therefore necessary to take account of the cloud, wind, and weather, as well as of the temperature, in examining a synoptic chart for discontinuities.

So far no mention has been made of the motion of the centre of the cyclone: this is determined primarily by the motion of the air in the warm sector. This air usually moves as a comparatively uniform current, and the centre advances in the direction and with the speed of the current of warm air. In other winds the path of the centre is parallel to the isobars in the warm sector, and the speed is approximately the same as the gradient wind in that sector. When the warm sector has vanished, the cyclone continues at first to move in the direction of the warm air above, but usually becomes stationary after a short time.

In fig. 1 the warm front and the cold front are indicated approximately by two thick lines radiating from the centre of the cyclone or 'low.' The warm sector is enclosed between these lines. On

this occasion the air in the warm sector was actually polar air, which had travelled a long distance towards the south over the Atlantic Ocean, and had then turned north again. In its passage over the ocean it had become rather warm and humid, and had therefore the fundamental qualities of the warm air of a cyclone. It can be seen that the cyclone was a vigorous one: there was a gale along the south of Ireland, in the west of England, in the Channel, and on the east coast, where the barometer was falling very rapidly. Next day, fig. 2, the gale was blowing in northern Holland and in Denmark, but the cyclone had become occluded; there was not much rain falling and the barometer was rising in most places, though still falling over Denmark and part of north Germany. The centre of the cyclone had moved almost exactly parallel to the isobars in the warm sector of fig. 1.

2. LINE SQUALLS.—This name is given to a type of storm which occurs frequently in western Europe. At a single place the characteristic feature of the storm is a rapid increase of wind to a gale or more, and a sudden change of direction, usually from south or south-west to west or north-west, with violent squalls and heavy rain or hail, sometimes thunder and lightning also. Simultaneously with the change in the direction of the wind, the barometer rises suddenly and the temperature falls 5° or 10° F. The squall approaches the place not from the direction in which the wind is blowing before the squall, but from the direction which the wind has after the squall. When the observations from many places are collected it is found that these squalls are not isolated and disconnected occurrences, but that they occur simultaneously at all places along a line, more or less radial from the centre of a cyclone, though not necessarily continued right to the centre and not necessarily a straight line; the line of the squalls advances with a speed approximately equal to the speed of the current of air behind the squall. This is usually different at one end of the line from what it is at the other, so that the line rotates somewhat as it advances. Practically every cyclone has line squalls associated with it, but they are usually of minor intensity. In practice the name line squall is reserved for those cases in which the wind in the squall reaches gale force and there are violent or rather violent storms of rain or hail. The cause of the line squall is the advance of a mass of cold air which cuts under the warm air in front of it. The cold air gets further forward at some height, 1000 or 2000 feet, above the ground than it is at the ground itself; the forward extension may be as much as four or five miles. The cold air up above moves forward unretarded by the friction of the earth's surface, and the warm air beneath the advancing upper cold air is squeezed out in front of it. The warm air is usually also humid, and, as it rises in front, the water vapour condenses, forms cloud, and accelerates the upward motion; conditions similar to those of a tornado are produced with violent squalls of wind. The actual front of the line squall, though there is a discontinuity all along it, is not continuously uniform. This is due partly to the irregularities which necessarily arise when a thunderstorm or tornadic development occurs; it is impossible for every point of the front to be the centre of a thunderstorm or tornado; it is also due partly to the irregularities in the advancing mass of cold air which are produced by the configuration of the land. The front of a severe line squall may therefore be taken to consist of a chain of disturbances with clouds rising up to 20,000 feet or more,

in which the vertical currents are intense enough to produce hail and thunderstorms.

Though the term line squall has been introduced in Europe and its peculiarities have been investigated specially in that area, it is by no means confined to the European area. It is probable that practically all the storms of brief and intense duration in which a rapid fall of temperature follows the violent wind and precipitation are of the same character as the line squall—viz. Southerly Bursters, Pamperos, Tornadoes.

3. **TORNADOES.**—The name Tornado originally introduced to describe the violent thunderstorms of the tropical Atlantic, is now usually applied to very violent storms affecting a comparatively narrow strip of country, 100 or 200 yards up to one mile in width, and varying in length from a few miles up to 200 miles or more. The tornado moves across the country (or sea) in a nearly straight line, with a speed of 20 to 60 miles per hour. [*N.B.*—This is the rate at which the tornado itself moves; it is *not* the speed of the wind in the tornado.] The speed of the wind in a severe tornado has not been measured; it is certainly well above 100 miles per hour, and probably exceeds 200 miles per hour in the most violent gusts. Tornadoes are more frequently reported from the United States of America than from any other region. The chart, fig. 7, shows the total

suddenly. Quite apart from any effect of wind, this sudden change of pressure would itself be sufficient to do considerable damage to any closed buildings.

At Edwadsville, where the storm was very intense, rain began about 5.20 p.m. and lightning at 5.25 p.m., after which the rain ceased for a time about 5.30 p.m. The schoolmaster at Edwadsville described the occurrence afterwards as follows: 'A few seconds before 5.50 p.m. we heard a noise resembling the hissing of an express locomotive. The sound grew rapidly in volume, at last resembling the rushing speed of many road lorries racing along. The oppressiveness increased. We endeavoured to move out of the room to the passage for greater safety when the panes of our window were broken by stones, tiles, slates, dried cement, and splintered timber. The missiles broke the venetian blinds, and struck the opposite wall.' During this tornado a corrugated iron sheet was carried from the roof of a store for a distance of more than half a mile, where it came in contact with a telegraph-pole, and was wrapped round the pole. A Congregational chapel was practically wrecked, and the pews in the front were all huddled up against the west side.

The air in a tornado is generally rotating about the centre, but cases have been observed in which the air appears to have moved directly towards the centre. It appears certain that quite near the centre the motion is always rotational, but that the air moves spirally towards the centre, and at some comparatively short distance away the component towards the centre exceeds on occasions the transverse component.

The rotation of the wind is usually in the same direction as in a cyclone—viz. counterclockwise in the northern hemisphere. There are some cases (about 5 per cent.) where the rotation is in the opposite direction, and on a few occasions two funnel clouds have been observed simultaneously rotating in opposite directions. The track of the tornado is usually from south-west to north-east. The winds

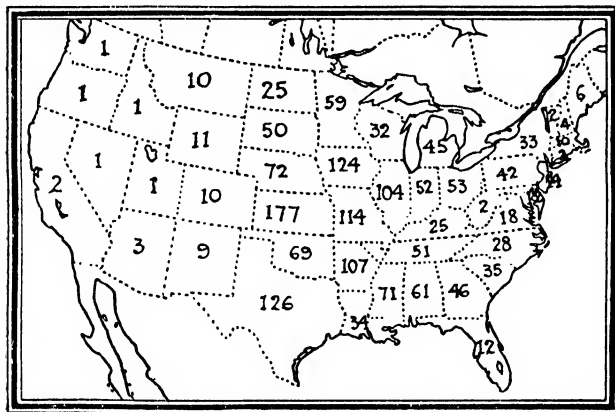

Fig. 7.—Number of Tornadoes in each state in 25 years.

number occurring in 25 years in each state. (Only a small strip of country in each state is actually affected by each tornado.) In the states most affected by tornadoes, between 10 and 20 lives are lost each year on the average from this cause; and the total damage to property caused in the United States by tornadoes in each year does not fall below 2 million dollars, and may reach 20 million dollars.

Tornadoes occur in Europe far less frequently than in the United States of America. There was one in South Wales in 1913; one in Holland in 1926. In the case of the storm in South Wales on 27th October 1913, this was of genuine tornado type. It travelled at a speed of about 36 m.p.h., and the width of the track, where severe damage was caused, was about 300 yards. The barometer at a place near the middle of the track fell suddenly 10 millibars and rose again immediately afterwards by the same amount. The pressure would therefore fall suddenly by about 20 lb. per square foot, and afterwards increase equally.

are said to be more violent on the right-hand side of the track of the centre, and this is what would be expected in a travelling storm rotating counter-clockwise; the speed of travel would be added to the speed of rotation on the right-hand side and subtracted from it on the left-hand side. The barometric pressure in the centre of a tornado is low, owing to the centrifrifugal action of the rotating air. Sudden falls of 10 millibars ($\frac{3}{8}$ in.) have been observed near the centre; in the centre itself the pressure must be sometimes as much as 50 millibars ($\frac{1}{2}$ in.) below the pressure outside the tornadic area.

There is, in fact, one actual record of a barometer at the centre of a tornado at Bizita in November 1898, which fell 44 millibars (1½ in.) in four or five minutes and immediately rose again the same amount. This intense fall of pressure must be accompanied by an equally intense fall of temperature; if air expands suddenly through a fall of pressure of 50 millibars it will cool about 10° F.

The depression of the barometer in the centre of a tornado can be related to the velocity of the rotating air in the following way: If the rotational velocity is v , and the density of the air d , then the depression of the barometer will be $\frac{1}{2}dv^2$, on the hypothesis that the moving air retains constant angular momentum about the centre. If the velocity v is 200 miles per hour, the value of $\frac{1}{2}dv^2$ is approximately 50 millibars.

The leading features of a tornado are: (a) the writhing funnel-shaped cloud swaying to and fro which projects from the main dark mass of cloud, itself seething and boiling like some huge witches' cauldron; (b) the rapidity of its approach; (c) the frightful roar, as of '10,000 freight-trains,' when the whirl itself comes; (d) the semi-darkness and heavy rain, sometimes hail, and thunder and lightning accompanying or closely following the whirl. The tornado passes as rapidly as it approached; in a minute all is over, and buildings lie wrecked, and people killed or injured.

If a tornado is seen approaching from the south-west there is usually just time for an alert man to get out of the danger-zone if he runs quickly to the north or north-west; but it is far better to seek shelter in a cellar or dug-out. One of the most heartrending catastrophes occurred in the case of a family who ran out of their house to avoid a tornado in May 1879. They were caught by the storm, and the father and mother and two children were killed. In Europe also storms of tornado character usually move from south-west or west towards north-east or east. The violent winds of a tornado are accompanied by a violent up-draught, and animals, vehicles, haystacks, and human beings have been carried up and transported hundreds of yards; boards have been blown as far as 2 miles from where the storm caught them.

4. TROPICAL CYCLONES.—Tropical cyclones are great whirls or vortices which travel as the air revolves; they originate over the ocean near the equator, for the most part between latitudes 8° and 12° north or south; they move usually westwards at first, then polewards, north or south according to the hemisphere, and afterwards towards the east. In the last stage they pass sometimes into cyclonic depressions of the temperate zone. They are seldom if ever formed over the land, and if they reach the land of a continent they rapidly lose their distinctive violence and either become depressions of the temperate zone or die out.

There are six regions of occurrence of these storms—viz. (1) North Atlantic Ocean. The West Indies, the Gulf of Mexico, the Caribbean Sea, and the coast of Florida. In this region the storms are usually called 'Hurricanes' or 'Hurricanes of the West Indies.'

(2) North Indian Ocean. Bay of Bengal and Arabian Sea. In this region the storms are usually called 'cyclones' after the Greek word for a 'circle.' The word 'cyclone' was, in fact, first introduced to describe these storms in 1848 by Piddington, who wrote the *Sailor's Horn Book for the Law of Storms*. (If Piddington's original analogy of these storms to the spiral coil of a snake had been followed, the word would have been 'cyclome'.)

(3) South Indian Ocean. East of Madagascar, near Mauritius and Réunion. In this region also the storms are usually called cyclones, but sometimes hurricanes.

(4) South Indian Ocean. Between Australia and the Cocos or Keeling Islands. In this region the storms are usually known as cyclones, or in Australia as 'Willy-Willies.'

(5) North Pacific Ocean. Philippines and China Sea. In this region the storms are usually called typhoons. Tropical cyclones also occur in the

North Pacific to the West of Mexico and Central America; and it has been suggested that some of them move west across the Pacific and appear as typhoons in the China Sea.

(6) South Pacific Ocean. From the coast of Queensland to Fiji, the Marquesas and the Low Archipelago called Tiamotu or Pannotu Islands. In this region the storms are variously known as cyclones, typhoons, or hurricanes.

It will be noted that these storms are not found in the South Atlantic Ocean, and that the majority of the areas have continent to the west and ocean to the east. But information for large areas of the Pacific Ocean is meagre, and the most recent view is that no large part of the tropical Pacific is free from these cyclonic storms.

The general character of a tropical cyclone is briefly as follows: On the outer limit there is a slow fall of the barometer towards the centre, roughly one millibar ($\frac{1}{3}$ inch) in 50 or 100 miles, and the winds are relatively light; the rate of fall of the barometer towards the centre increases usually gradually and the wind increases similarly; nearer the centre the fall of the barometer is very rapid, it may be as much as one millibar per mile, and the wind blows with hurricane force; over a small area at the very centre there is usually a calm, with a nearly steady barometer: this is called the 'eye' of the storm. This area varies, diameters of 5 to 15 miles having been observed. The vortex with winds of hurricane force may be as small as 20 miles in diameter, or it may extend over an area of 400 miles in diameter. The barometer is sometimes very low indeed in the centre of a tropical cyclone, though not usually so low as in the centre of the deepest depressions of the temperate zone. In one case, however, the barometer at the centre reached the lowest level ever recorded at sea-level. This was in the famous False Point cyclone of 22d September 1885, when the lowest reading was 919 millibars (27.14 in.).

On the outer limit the weather is fair, often with cirrus cloud or cirro stratus, which causes haloes round the sun or moon, and may be responsible for the lurid sunsets which are among the characteristic signs of an approaching cyclone. Nearer the centre the sky is overcast and rain, sometimes hail, falls torrentially; thunder and lightning may also occur.

There is sometimes a region of light rain between the fair weather and the torrential downpour, but the transition may be almost instantaneous. Some investigators consider that the area of rain is elliptic in shape, prolonged towards the rear of the storm. In the eye of the storm the sky frequently clears and the rain ceases, but cases occur in which the sky continues overcast even in the centre; sometimes lightning is observed near the centre, but as the diameter is relatively small, the origin of the lightning may be in the storm region around. The temperature is usually rather lower (2° F. to 4° F.) within the area of the storm than in the region outside, and the relative humidity is nearly 100 per cent., although just outside the storm it may be only 80 per cent. The decrease of temperature and increase of humidity are probably due to cooling of the air partly by the torrential rain and partly by the reduction of pressure. The amount of rain which falls during the passage of a tropical cyclone is usually large and may be excessive; amounts of 20 inches have been measured on islands over which the centre has passed. A reduction of pressure of 10 millibars would correspond with an adiabatic cooling of nearly 2° F.

Records of the speed of the wind in the worst cyclones are lacking, because the instruments are blown away. Speeds of over 100 miles per hour have been recorded, and it is probable that in

squalls the velocity sometimes exceeds 150 miles per hour.

The following are descriptions of hurricanes at sea in the Bay of Bengal and in the West Indies: 'In the evening the weather was dark, gloomy, and threatening, and at midnight there were very heavy squalls and rain, the wind being ENE., force 9. The wind continued from NE. or ENE. strong to a gale until noon on the 2d, but at 2 P.M. the ship ran into a dead calm, and a number of land birds, such as a hawk, a paddy bird, several smaller kinds, some butterflies and insects, and also several dragonflies. The wind went right round to SSW. and began to freshen, and by midnight was blowing force 11 from SSW. The distance run by the ship during the relatively quiet period was about 10 or 12 miles. In the evening the moon was just visible. There was a good deal of thunder observed to the NE.'

'There was an ugly threatening sunset on 24th August 1924. The whole heavens assumed a lurid red colour intermingled with orange and purple, and the sky to the westward retained a dull red glow long after the sun went down. During the night the barometer fell comparatively rapidly, and at 6 A.M. the wind having increased to force 11, with squalls of hurricane force, the ship was hove to. At this time the wind was blowing from the ESE. At 3 P.M. the wind veered to S., and returned full hurricane force. At 3.30 P.M. it changed to SW. At 4 o'clock the barometer began to rise. There was no change in the weather or conditions, but the wind veered gradually to WSW. The barometer rose rapidly and the wind decreased. Owing to the rain and spindrift the visibility during the hurricane was very poor (i.e. it was not possible to see much more than 200 yards). The dry and wet bulb readings at 4 A.M. on the 25th were 80 and 74, and the same at 8 A.M. At noon they were 76, 76, and the same at 4 P.M. By midnight they were 80, 76. There was no thunder during this hurricane, but lightning was observed to the eastward after the hurricane had passed and the wind had changed to WSW.'

There are in the different regions definite periods of the year when cyclones occur, and the table below shows the number recorded per month in the past: the period of years for which records are available varies, and the numbers have been reduced to correspond with a ten-year period. Many storms probably occur which are not recorded, either because they do not pass near land or only near uncivilised lands. Some of the severest storms in the different regions have occurred in the months at the end of the cyclonic period: a notable one visited Mauritius on 29th April 1892—seventeen days later than any previously recorded cyclone there—and was so severe that the sugar-crop was reduced from 120,000 tons to 70,000 tons.

It is seen from the table that the season of tropical storms is, broadly speaking, late summer and early autumn in both hemispheres. The Bay of Bengal storms are divided into two classes. Class I. are the more severe storms with winds exceeding force 10. Class II. are storms with winds between forces 8 and 10.

The number and intensity of tropical cyclones vary greatly in different years: in the West Indies in 1886 and 1887 there were eleven hurricanes in each year, while in 1897 and in 1913, 1914 there were none. There does not appear to be a common cause for these variations, inasmuch as a year of maximum frequency in one region may be a year of normal or of minimum frequency in another region.

The damage caused by tropical storms has been already mentioned in the case of an exceptionally late storm at Mauritius. Not only is the damage to property often severe, but great loss of life is also frequently caused. For example, in the storm of 16th–17th August 1915 the death-toll at Galveston was 3000, and the damage to property six million dollars, while the same storm caused about 6000 deaths in other areas and enormous damage to crops and property in one-half of the State of Texas. The West Indian hurricane which passed over Miami, Florida, on 18th September 1926 is illustrated in the map, fig. 8. The barometer at the centre fell to 935 millibars (27.61 inches) at Miami at about 6.30 A.M. on 18th September, and the central lull lasted about half an hour. A wind velocity between 120 and 130 miles per hour was measured before the anemometer was blown away. More than 200 people were killed, thousands rendered homeless, and the damage to property was nearly 100 million dollars. Four days earlier, on 14th September, an intense hurricane had passed just west of Bermuda, the Miami cyclone being then just north of St Kitts. It travelled at about 14 miles per hour.

In the typhoon of 20th April 1905 over 2000 houses on the island of Ponape in the Eastern Carolines were destroyed. A storm in Queensland in February 1927 caused the loss of over 40 lives and damage to property estimated at £3,000,000. Sometimes, however, the rainfall associated with these storms, which falls over an area much larger than that of the violent winds, is most beneficial, especially in India.

In all the regions of tropical cyclones, systems of warnings have been developed, though not all to the same extent. The most efficient are probably those of the United States in the West Indies, of India in the Bay of Bengal, and of the United States, Japan, and Hongkong in the case of typhoons of the North Pacific. One of the principal difficulties of effective warning arises from the fact that these storms originate over the ocean where

there are no fixed observations, but against this must be set the relatively slow movement of the centre, usually only 10 or 12 miles per hour. Warnings inland are effective in reducing the loss of life by enabling persons to get into places of relative safety; warnings to ships may enable them to avoid the storm altogether.

In the case of ships, a knowledge of the system of wind in cyclones and of the normal tracks is of the highest importance; the wind does not blow exactly in circles around the centre, but is inclined towards the centre at an angle of approximately 30° with the tangent to the circle. The direction of the centre can therefore be found by drawing a line making an angle of 60° with the direction towards which the wind is blowing; there are, however, variations from the average value of 30°

of the angle: it may be as small as 20° or as large as 40° . It is larger on the outskirts of the storm than nearer to the centre; in fact, it is better to assume an angle of 45° on the outskirts and an angle of 25° if the barometer has fallen 10 millibars. Another observation of importance to mariners is derived from the swell caused by the storm; this swell moves away from the centre and may be observed when the centre itself is hundreds of miles away. The principal rules for mariners

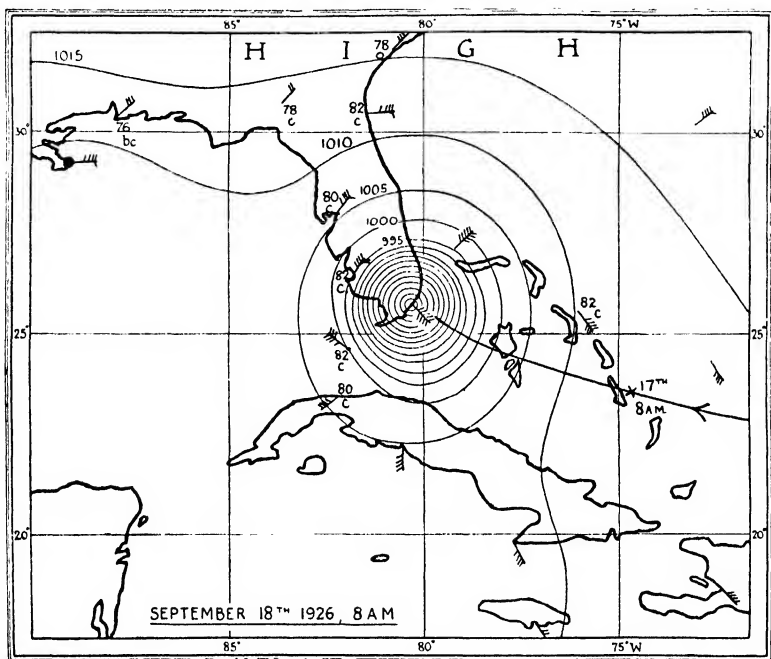

Fig. 8.—Miami Hurricane. Isobars for every five millibars.

are: (1) if possible keep out of the dangerous half of the cyclone, i.e. the half on the right-hand side of the direction of motion of the centre in the northern hemisphere, and the half on the left-hand side in the southern hemisphere; (2) in the northern hemisphere heave to on the starboard tack, and if the wind veers, remain heve to. If the wind is steady in direction and increases, or the barometer falls, run with the wind on the starboard quarter. If the wind backs, run with the wind on the starboard quarter until the barometer rises. In the southern hemisphere follow the same rules, replacing 'veering' by 'backing,' and *vice versa*, and 'starboard' by 'port.'

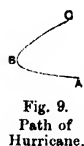

Fig. 9.
Path of
Hurricane.

It has already been mentioned that tropical cyclones usually begin to move westward and later in their life turn and move eastwards. The actual tracks are usually something like the curve ABC. The point B is called the recurve. It is at this point that the storms frequently reach their greatest intensity. It has been suggested that the storms move round an anticyclone whose centre is over the ocean far

to the westwards of the point B; the direction of the general wind circulation around such an anticyclone would be the direction ABC, and in the latitudes in which these cyclones occur the speed of the wind at moderate heights in the atmosphere would be of about the same magnitude as the speed at which the centres of the cyclones move.

On some occasions a West India hurricane changes into a cyclone of temperate latitudes after travelling some distance along BC of the curved path; and such storms have been traced right across the Atlantic from the coast of Florida to the British Isles. In such cases the speed of travel in the temperate zone is greater than the speed in the tropical part of the track.

The place of origin of tropical cyclones is the doldrums, the region of calms between the two systems of trade winds. If this region is actually over the equator, there will, as a rule, be no disturbances in it except wind-squalls, waterspouts, and heavy showers. It is only when the doldrums are some distance north or south of the equator that the instability, which gives rise to these minor effects, can act as the trigger to concentrate the angular momentum due to the earth's rotation in a

well-defined cyclone. This is in all probability the reason why tropical cyclones are not found in the South Atlantic Ocean—the doldrums are never far enough south.

If a fluid has a motion of rotation about a centre towards which it moves, then the speed of rotation increases towards the centre. A familiar instance of this is the swirl of water running out of a bath—the rotation is inappreciable at a distance from the hole through which the water escapes, but it becomes intense enough near the hole to cause a marked depression of the surface. A tropical cyclone is analogous—the velocity of rotation is roughly twice as great 20 miles from the centre as it is at 40 miles, and the isobars must conform to the rotation. The question naturally presents itself, 'What corresponds with the plug?' No perfectly satisfactory answer has been given to this question, partly because the analogy with the plug is not itself perfect. The important fact is not the plug, but the vertical current resulting from its removal in the bath; and a vertical current over a definite area is an essential condition for the formation of a tropical cyclone. Such a vertical current may arise in the following way.

In air free from cloud which is warmed gradually at the bottom (or cooled above) the rate of fall of temperature with height is $1^{\circ}\text{F. per } 180 \text{ feet}$ ($1^{\circ}\text{C. per } 100 \text{ metres}$); if the air at tropical temperatures is saturated with moisture and cloud is formed the rate of fall is about half as great— $1^{\circ}\text{F. for } 350 \text{ feet}$ (or $1^{\circ}\text{C. for } 200 \text{ metres}$). If a comparatively thick layer of relatively cool air over the ocean lies beneath a slightly warmer layer of dry air, the lower layer will gradually take up moisture from the ocean and simultaneously, in tropical regions, rise in temperature. After a time the lower layer may become as warm as the upper layer, and when that stage is reached the lower layer will begin to rise into the upper layer, and photographs of clouds show that when this happens the rising air does not move upwards in threads over the whole region, but bursts through in masses. As this lower air, saturated with moisture, moves upwards its temperature will fall only half as fast as the temperature in the dry layer, so that it will always be warmer than the surrounding air at the same level and the upward motion will be intensified. Near the surface, air will move inwards towards the region of the upthrust and the air nearest the ocean surface will have the greatest moisture content of any air in the region; it will therefore form cloud at a lower level and the tendency to upward motion will be further intensified.

If there is little or no rotational motion pre-existing a waterspout or local whirl will result which will be gradually damped out by the descent of dry air from above. If, however, there is a pre-existing rotational motion, as there must be in a region where the earth's rotation is effective, the inflowing air will form a whirl, and, once started, this whirl will be kept going for a considerable time by inertia. If the whirl were stationary it would be practically symmetrical and would gradually die out, but a whirl would usually move with the general current in which it was formed. Owing to this motion and the consequent dissymmetry the whirl will be continually taking in fresh supplies of air from the surface layer, and not air which has descended from above and which would supply no fresh source of energy to replace that dissipated by friction. This qualitative description of the theory of formation of these storms is in general accordance with the facts. Storms rotate counter-clockwise in the northern hemisphere and clockwise in the southern hemisphere: which is conclusive proof that the effect of the earth's rotation is the decisive factor. They also form after air has been moving

slowly for some days over the ocean and has become warmed and saturated; the fact that they do not form more frequently indicates that special conditions in the upper air are also an essential factor; they do not form over the land although local warming is more intense than over the oceans, which is conclusive proof that the moisture evaporated from the ocean is also an essential factor; and the invariable occurrence of heavy rain in the area of the storm shows that air saturated with water vapour is continuously ascending and cooling and thereby condensing the vapour into rain.

It has recently been suggested by V. Bjerknes that tropical cyclones form as waves in a surface of discontinuity in a manner similar to that in which cyclones of temperate latitudes form. The air in the trade winds constitutes the 'polar' air; the surface of separation (in the northern hemisphere) slopes from north to south and also from west to east over the Atlantic; it will therefore come lowest in the neighbourhood of the Cape Verde islands, where, in fact, many of the tropical cyclones of the North Atlantic originate.

5. THUNDERSTORMS.—These are commonly divided into two types. The first type is similar in origin to the waterspout; air near the surface of the earth is warmed during the day by the sun's radiation; this air either contains originally appreciably more water-vapour than the air above it, or it gains water-vapour by evaporation until its water-content is sufficiently increased. The heating of the air near the surface starts convection in the lower layers and a stage is eventually reached when condensation begins. If the vertical temperature gradient in the drier layer above is greater than the rate for ascending saturated air the lower layer then breaks into the drier layer and forms towering clouds of cumulus type; if the comparatively large vertical temperature gradient in the drier layer persists to a great enough height, the clouds grow high enough first to produce rain; this rain would normally fall as a heavy shower, but the vertical upward current in a cloud produced in the manner described becomes very strong and carries the raindrops up with it, and by this very process increases the intensity of the rain when it does fall, and probably also produces the necessary electric field to give the thunderstorm. There are probably in every thunderstorm of this type the same violent whirls as occur in waterspouts; but the whirls are produced at considerable altitudes in air which is already filled with cloud; the whirls are not, therefore, directly visible. Thunderstorms of this type are always produced in relatively calm conditions; they are usually sporadic and move slowly.

The second type of thunderstorm is essentially a phenomenon of line-squall type. It is produced at the front of a mass of cold air which is under-cutting a mass of warmer and, generally, more humid air. Thunderstorms of this type are associated with strong and even violent squalls of wind, and the thunderstorm moves comparatively rapidly across the country.

Heavy rain falls as a rule with thunderstorms of both types, and, in temperate latitudes, hail is also frequent. Hail also occurs, though less frequently, with tropical thunderstorms. The cause of the formation of hail may be described briefly as follows. Owing to the resistance of the air a drop of water falling through the atmosphere does not go on falling with increasing velocity, but rapidly arrives at a certain limiting velocity dependent on its size; the limiting velocity increases with the size of the drop up to a value of about 25 to 30 feet per second for drops $\frac{1}{8}$ -inch in diameter. These are the largest drops which can fall without breaking up rapidly into smaller drops. If there-

fore the upward current in a thunderstorm exceeds 25 to 30 feet per second any rain drops which get into the current are carried upwards with the current; as the temperature decreases rapidly upwards the drops may be carried up through a region where the cloud consists of minute super-cooled water-drops and fine ice-crystals; the drops freeze and collect further ice in the cloud; they may then be ejected at the top of the current and fall to earth, or they may fall some distance only into the rain section of the cloud and there be caught again in a strong ascending current. It is possible in this way to get several layers in a hail-stone consisting of clear ice alternating with softer white snow-like layers. The clear ice comes from the water or super-cooled water-drops, while the snow comes from the fine ice-crystals.

It is now generally agreed that the separation of positive and negative electricity in a thunderstorm is effected through the agency of precipitation, the larger drops carrying down a charge of one sign and the smaller drops or cloud particles carrying the charge of opposite sign. It is further proved that generally a lightning flash must start from a seat of positive electricity and develop or branch towards a seat of negative electricity. The precise manner in which the large and small particles acquire their charges of opposite sign is not yet completely understood. It is generally considered either that the charges arise from disruption of raindrops or that the charge is induced on the drops by the earth's electric field. When a water-drop breaks into two the two new drops are both positively charged and the surrounding air and any minute drops in it negatively charged. As there must be a large number of drops which are broken into two in the violent upward currents of thunderstorms, it is certain that some, if not all, of the separation of electricity arises in this way; and the theory is supported by the fact that the large drops of thunderstorm rain are found to be positively charged. It has been objected against this theory of the origin of the charges in a thunderstorm that the process would result in the upper part of the cloud having a negative charge, whereas observations of the change in the electric field in a thunderstorm suggest that the upper part of the cloud has more frequently a positive charge. The reconciliation of the apparently divergent evidence appears to lie in discharges from the cloud downwards which do not extend to the earth. Most of the electric discharges in a thunderstorm take place between the upper and lower parts of the cloud; the discharges (lightning flashes) to earth are much less frequent; they usually go from the lower part of the cloud to the earth, but sometimes from the upper part of the cloud to the earth. Sometimes, too, discharges go from the top of the cloud to the conducting upper atmosphere (Heaviside layer). The potential gradient in the atmosphere must reach something like 3 million volts per metre before a lightning discharge can begin; with a thunderstorm 6 miles distant variations in the potential gradient of 1000 volts per metre occur. The energy dissipated in a single lightning flash is enormous—10,000 million joules; in other words, if a lightning flash occurred every ten seconds energy would be wasted at the rate of 1,000,000 kilowatts. Lightning discharges take place more readily to forests than to bare ground, and, *ceteris paribus*, to mountain summits and ridges than to valleys or plains. In this latter connection, however, it is to be noted that the thermal conditions which give rise to thunderstorms of the first type occur more readily over the valleys than over the ridges, and the thunderstorms, therefore, have a tendency to form over the valleys and to move along them.

In mountainous country the frequency of thunderstorms appears to vary little with altitude so long as the mountains are of moderate height; the frequency may even increase slightly with altitude. But in Switzerland the frequency is definitely less at great altitudes than at intermediate and lower heights; places above 6000 feet have only half as many thunderstorms as places below 1500 feet, and in Java the thunderstorms are said to move towards the plains even when they originate on the lower slopes of the mountains. As water and water-vapour play a fundamental part in thunderstorms, the decrease in the amount of water-vapour in the atmosphere at great heights may cause a decreased frequency of thunderstorms over high plateaux or mountain regions where the general level of the land is very high over considerable areas.

The distribution of thunderstorms over the earth's surface shows much variation. If the number of days in the year on which thunder is heard is taken as representing the frequency of thunderstorms, the regions of greatest frequency are Madagascar (95 days), Central Brazil (106 days), Panama (136 days), Southern Mexico (143 days), Central Africa (150 days), and Java (223 days). In Java thunderstorms occur on the average on 6 days out of 10. Regions of least frequency are the polar regions and the north of Norway, the north of Iceland, Greenland and Northern Canada, where thunderstorms occur less frequently than once a year. At places north of the Arctic circle thunder occurs about once in ten years. Thunderstorms are also relatively infrequent on the west coasts of North and South America and the west coast of Africa, except close to the equator.

Over Europe the average frequency is 17 days, with a maximum of about 40 days in Württemberg and Bavaria. In Ireland the average frequency varies from 4 days on the coast to 8 days inland; in Scotland from 2 or 3 days in the Shetlands and Hebrides to 7 or 8 days inland; in England and Wales from 3 or 4 days on the west coast to 15 days inland. Thunderstorms over the land occur most frequently in the afternoon between noon and 6 P.M.; about 60 per cent. come in this period. Thunderstorms over the ocean occur most frequently at night, between midnight and 4 A.M.

Taking the whole world, there are on the average nearly 2000 thunderstorms occurring at any one time; and every second there are about 100 lightning flashes. Energy is being continuously dissipated in thunderstorms at the rate of 1000 million kilowatts. The magnitude of this may be better understood by stating the cost of the energy, calculated at the rate of one penny per unit (kilowatt hour); it is £4,000,000 per hour, or £100,000,000 per day. There are indications of an extra-terrestrial influence on the frequency of thunderstorms. The number occurring in Siberia, for example, increases and decreases systematically with the number of sunspots.

6. SCIROCCO, SIMOOM, WATERSPOUTS, DUST-STORMS, HABOOBS, BORA, MISTRAL, PAMPELO, SUMATRAS.—*Scirocco* or *Sirocco*.—This term was originally used for a strong and gusty southerly wind in Italy. In southern Italy it was hot and dusty. Further north the same wind, after passage over the Adriatic, was damp, and brought cloud and rain. The term 'scirocco' is now generally used for a high wind in any part of the world which is hot, dry, and dusty. There are, however, many local names for it: in Egypt, 'khamisin'; in Syria, Arabia, and Persia, 'simoom'; in Tripoli, 'ghibli'; in Tunis, 'chili'. A similar type of wind in Australia is called a 'brickfielder.'

The scirocco wind is a desert wind, and it brings with it the characteristics of the region from which

it comes; sometimes, too, it brings thick storms of dust. Usually over the scirocco wind, which is not more than 2000 or 3000 feet thick, there is a westerly wind. In some cases the heat and dust brought by a scirocco are so marked that they cause the death both of men and animals. If a scirocco comes in the spring when the trees are in bloom or the crops tender, it is liable to cause almost a complete loss of harvest, especially of the vine and olive, and also sometimes of corn and maize. After a scirocco the temperature falls, and the air becomes humid; the sudden change frequently causes illness, fever, and heart trouble. The scirocco arises through a depression in the neighbourhood of a desert region which causes the wind to blow strongly from the interior of the desert; consequently this wind is not a purely local phenomenon, but forms part of a general wind system and spreads over a wide area. In the Mediterranean area the scirocco comes usually on the east or south-east side of a depression moving westwards over the sea; thus in addition to the scirocco's progress northwards, it also spreads eastwards. It may occur in winter as well as in summer, though in the winter season its characteristic features are dryness and dustiness rather than high temperature. The sand or dust brought by a scirocco may be so thick in the air that the sky is entirely obscured.

Simoom, or Poison Wind.—This is a high wind of scirocco character which blows more particularly in Persia and Sind. It is remarkable in combining a high velocity, 30 or 40 m.p.h., and a very high temperature, 120° F. or more. It gains its name from the fact that men or animals die if exposed to it for any length of time. It is now considered that death is caused from purely physical causes, and not from any obscure poison in the wind. The explanation is briefly as follows: If the air temperature is above 98° F., the heat conveyed from the air to the human body is balanced by heat lost through evaporation (perspiration). In a wind the body receives more heat from the air and loses more by evaporation than it does in calm air, but there is a limit to the loss which can be effected by evaporation from the skin; if the wind and temperature increase until this limit is passed, the body receives more heat than it loses; this is fatal if it persists for hours. The limit is believed to be reached by a wind of 30 m.p.h. if the temperature is 125° F.

Khamisin is a storm of scirocco character in Egypt; the wind is usually from the south or south-east. These storms come usually in March, April, and May, and fill the air with sand from the desert. They are reputed to occur on about 50 days, whence the name 'khamisin' is derived.

Waterspouts are similar in character to tornadoes, but are much smaller in size, in intensity, and in duration. They are very frequent near the equator, and occur in spring and summer throughout the temperate zone. The following is a description of a small waterspout observed from Loch Venachar in Scotland in 1917. On a quiet, hot summer day with an overcast sky the lower surface of the cloud appeared at one place to become agitated; suddenly a spike of cloud thrust downwards from the spot, receded a little, projected still further, and then rushed to earth, forming an irregular column like a thick twisted rope; after a few minutes this column broke and disappeared. When a waterspout is formed over the ocean the surface of the water bulges upwards, and spray begins to rise; sometimes it appears to join the funnel descending from the cloud. Sometimes the spray appears to rise around the funnel like the splash rising round a heavy stone dropped into water. The spray from the agitated sea can be seen both before the funnel from cloud to sea appears and after it disappears;

the cyclonic whirl is, in fact, present in the atmosphere some time before the waterspout is visible, and persists some time after the waterspout disappears. Some of the spray from the sea may be carried up, but it is probable that the major part of the fall of water in the waterspout comes from the cloud. Water in the atmosphere invariably breaks up into drops, and the largest drops cannot fall if the upward current is greater than about 20 m.p.h.; any water in an upward current with a greater velocity than this would be carried upwards, and would fall in the region surrounding the intense upward current.

Dust-devils are small whirling storms which form over the land in hot countries such as Mesopotamia, and in nearly all desert areas. They usually occur in the middle of the day and die away in the afternoon. They reach heights of several hundreds of feet, and they owe their name to their fantastic appearance as they move across the burning sands. There is no rain with these storms, and the energy available for their formation arises solely from the intense heating of the surface air; each one is therefore, as a rule, of comparatively short duration. The diameter of a dust-devil may be as small as 5 feet or as large as 25 yards. Dust-devils move frequently at 10 to 15 m.p.h., either with the wind or sometimes across the wind; occasionally they remain practically stationary; occasionally they travel at speeds of 25 m.p.h. or more. The direction of rotation of the air in a dust-devil is sometimes clockwise and sometimes counter-clockwise; it is determined by purely local and usually accidental circumstances, and not, as in cyclones, by the rotation of the earth; though it is possible that those dust-devils in which the rotation is clockwise die out more quickly than the others which rotate in the direction of cyclones.

Haboobs.—A haboob is a very unpleasant type of sandstorm which occurs in Northern and Central Sudan, particularly in the region near Khartoum and east of it. They come chiefly in the period May to October (rainy season), though they may also occur in the period November to April (dry season). They last from half an hour to several hours, the average duration being 2 or 3 hours. The dust is raised frequently to heights of over 3000 feet, and along the front of the storm, which may extend to 20 miles or more, there appear to be violent up and down currents. Haboobs are most frequent in the late afternoon, and in the rainy season about half of them are accompanied by rain, and one in three is followed by thunder and lightning. In the rainy season the wind in a haboob is between south and east, and changes to west after the storm; in the dry season the wind is northerly; the speed of the wind is usually not more than 40 miles per hour, but may reach 50 or 60 miles per hour. At Tokar, near the Red Sea, haboobs pile up dust in the course of July and August as high as 15 feet against obstacles transverse to the wind.

Reshabar (Black Wind).—A very gusty wind which blows from north or north-east in southern Kurdistan both in winter and in summer. It begins usually in the early morning, and practically never in the middle of the day. It is characterised by alternation of gusts and calm periods, the transition being almost instantaneous from a calm to a wind of 50 m.p.h.

Sumatras.—A sumatras is a storm of brief duration which occurs in the Malacca Straits, chiefly in the period April to October. Sumatras always occur at night between 9 P.M. and 3 A.M., and the wind is usually south-westerly, reaching 40 or 50 miles per hour in the squall. A bank of cumulo-nimbus spreads over the sky, and when the edge of the advancing bank of cloud has just passed the observer's zenith the squall breaks and is nearly

always accompanied by thunder, lightning, and heavy rain. The storm at any one place is usually over in less than two hours; although they affect the coasts of the Straits, especially between Malacca and Penang, they do not penetrate far inland, even over flat country. They are probably gravitational winds (see below).

Southerly Busters.—These are Australian storms of line-squall character experienced, especially in New South Wales, during the spring and summer months, October to February, occasionally also in September and March. After a period of high temperature varying from 3 hours to 3 days, with winds from west or north-west in early and late summer and from north-east near midsummer, cirro-cumulus clouds appear in the south, followed by a heavy roll of cumulus. An hour or so after the appearance of the roll-cloud the wind drops for a short time and then a whirl of dust ushers in the 'burst'; in a few moments a gale from the south is blowing; temperature falls rapidly between 15° F. and 20° F.; in an extreme case the fall was 37° F. A storm of similar type is experienced in South Africa in the neighbourhood of Durban; and in South America, where it constitutes the true pampero.

Bora, Mistral, Chinook, Pampero, Gregale.—The majority of storms are associated with cyclonic whirls, and arise over the sea or over land approximately at sea-level. They do not depend upon those differences in the atmosphere which arise from differences in the level of the ground. The winds in such storms are considered to arise from the horizontal difference of pressure. There is another type of wind which plays an effective part in certain storms. This wind is commonly called a 'gravitational' wind. It is caused when air on a plateau or mountain is cooled to a lower temperature than the temperature appropriate to its height. This cold air in such circumstances tends to run downwards. It produces, for example, the wind known as the 'valley' wind. The reverse effect occurs when air over the land or high ground is warmed to a higher temperature than that appropriate to its position. The warm air tends to rise, and air moves inward to take its place. The sea-breeze is an example of a wind caused by this effect. In most parts of the world the sea-breeze is a light or moderate wind, but on the coast of Northern Chile and Peru the sea-breeze in the middle of the day blows with the force of a gale.

Storms in which the gravitational wind plays its part are the Bora of the Adriatic, the Mistral of the south of France, the Gregale of Malta and Sicily, the Chinook wind of Canada, and the pseudo-pampero wind of South America (the true Pampero partakes more of the nature of a line-squall). The Bora, literally the north wind, blows for about thirty days in the course of the winter along the Adriatic coast from Trieste to Lesina. It is rarely a north wind, but most frequently a north-east wind, and sometimes an east wind. It is a very squally wind. It blows sometimes with a velocity of 40 or 50 miles per hour, but in gusts the speed reaches 80 or 90 miles per hour. It occurs when there is an anti-cyclone over Europe and a low pressure over Italy or the western Mediterranean, in the winter months. It reaches its maximum intensity about 9 A.M., and decreases in the afternoon and evening. It is caused by the cold air from the Balkan tableland flowing down to the Adriatic and reinforcing the general north-east current arising from the pressure distribution. A similar wind to the Bora blows in winter on the north-east coast of the Black Sea. It is sometimes so intense and so cold that the spray which it blows up from the sea is frozen, and covers ships with a thick crust of ice: this is at times so heavy that ships sink in

harbour. The Mistral (or master-wind) is a north wind which blows on the Mediterranean coast of France in the winter months, sometimes with great violence. It occurs when the polar air has broken through to the Mediterranean behind a depression which has moved east across the British Isles or Northern France. The natural velocity of the general current is intensified partly by the constriction between the Alps and Pyrenees, and partly by the gravitational effect arising from the cold air on the tableland between the Garonne and the Rhone. The Gregale, or Greek gale (so called because it comes from the direction of Greece), is a north-easterly gale affecting specially the Mediterranean in the neighbourhood of Sicily and Malta. It sometimes blows consistently for two or three days in winter. It is similar in character to the Bora and Mistral, and occurs under similar conditions.

7. CHARACTER OF WIND—HISTORIC STORMS—STORM WARNINGS.—The wind in a storm is by no means steady either in speed or in direction: its character is best understood from an actual instrumental record. Fig. 10 is a copy, on reduced scale, of a record taken in the island of Trecce during the storm of 28th January 1927. The upper trace is the record of velocity, the scale in miles per hour being printed at the side of the record, which goes from 9 A.M. on 28th January to 9.15 A.M. on 29th January. It is clear that the wind is oscillating between wide limits; at the beginning it falls sometimes below 30 m.p.h. and rises sometimes above 60 m.p.h.; the mean speed at that time, taken from the middle of the rather ragged ribbon, was about 44 m.p.h. The lower trace is the record of direction; at the beginning the wind was southerly, but actually oscillating between SSW. and S. by E. At about 10.40 A.M. there was a sudden squall; the speed increased to over 80 m.p.h.; and there was, as there generally is with squalls, a simultaneous change in the direction, though only a small one. About 2 P.M. the wind began to change towards west, and to increase still further; by 3 P.M. the gusts were rising above 90 m.p.h., and the lulls falling below 40 m.p.h.; and at 3.25 P.M. there were several gusts of 100 m.p.h. and one of 108 m.p.h., the record rising above the top of the chart, up to the second A of the printed word Anemogram. There was another similar fierce gust 20 minutes later at 3.45 P.M., after which the storm began slowly to abate. Some idea of the 'buffeting' of a storm can be obtained from this record: at the time of the most violent gusts the pressure of the wind was varying rapidly between 30 lb. or more per square foot and 5 lb. per square foot; in other words, a medium-sized man would find himself pushed with a force equal to 100 lb. weight, suddenly falling to 15 lb., and then up to 100 lb. again; and not in a constant direction, but now a little to the right, now a little to the left.

It is appropriate here to mention some notable storms. The Armada storm of 30th May 1588, in the English Channel was of very brief duration; it was probably of line-squall type. Defoe's storm of 26th November 1703 was one of the most violent general storms in Britain; the cyclonic centre crossed the midlands of England, and the worst damage was caused in the south of England. Reference has already been made to the storm in the Black Sea during the Crimean War on 14th November 1854, which sank the French battleship *Henri IV.*; another storm, which contributed to the success of the efforts to establish telegraphic collection of weather reports, and the issue of storm warnings, was the *Royal Charter* storm of 25th October 1859. At 7 A.M. on that day the *Royal Charter* was wrecked at anchor off the north coast of Anglesey; the storm was caused by an intense

(By permission of the Director of the Meteorological Office.)

secondary depression. In the *Eurydice* storm of 24th March 1878 the training ship *Eurydice* was caught unawares with ports open off the Isle of Wight and sank in sight of shore; the storm was due to a line-squall; the wind changed suddenly from SW. to NW. and temperature fell more than 10° F. Another storm due to a line-squall was the famous *Tay Bridge* storm of 28th December 1879, when the new bridge across the Tay was blown down, and the train full of passengers plunged into the river beneath. A storm of different type was the snowstorm of January 18–19, 1881; this was caused by an ordinary cyclone which crossed the south of England, and brought a heavy fall of snow with easterly gales. Some trains were completely buried by the snow; railway traffic was disorganised; London was deprived of its milk supply. The *Sanana Hurricane* (1889) came upon the island from the north-eastwards; seven war-ships (viz. three American, three German, and one British) and six merchantmen were in the harbour; the British warship *Calliope* steamed out to sea when the hurricane was observed approaching, and was saved; all the other ships were lost. In the *Berlin* storm of February 20–21, 1907, the Great Eastern Railway Company's steamer *Berlin* was wrecked, with much loss of life, off the Hook of Holland. This storm was due to a large and very deep depression whose centre passed north of Britain to the coast of Norway, and caused severe westerly and north-westerly gales in the North Sea. In the storm of 3d December 1909, the Isle of Man steamer *Ellan Vannin* was lost with all her passengers and crew off the mouth of the Mersey. This was again a cyclonic storm, the centre of the depression being near Herwick-on-Tweed when the catastrophe occurred in the severe wintry NW. gale behind the depression.

The following table shows the highest winds recorded in storms crossing the British Isles. The speeds are those recorded in gusts of duration long enough to move the float of the recording anemometer. Greater speeds would be recorded if a more sensitive instrument were used, but they would be of very brief duration—one or two seconds only.

Storm Warnings are issued by meteorological services of all countries. They vary to some extent, but the signals consist generally of one or two cones which appear as triangles when viewed from a distance. In Europe, if a single cone is used, it denotes a N. gale if the point is upwards and a S. gale if the point is downwards. If two cones are used together they denote a NE.

gale if both point upwards, a SE. gale if both point downwards, and a hurricane if they are base to base. In some countries a ball is used in addition to cones. The ball indicates 'Be alert, a disturbance exists; no certainty that it will affect these coasts or that the wind will reach gale force.'

In India and the Indian Ocean warning signals consist of a cone, a drum, and a ball. The cone and drum alone are used as 'danger' signals to indicate a slight or moderate cyclonic storm, while the cone or drum in conjunction with the ball are used as 'great danger' signals to indicate a cyclonic storm of great intensity.

In the United States of America and in Australia the storm-signals consist of two red flags with black centre and a red or white pennant. The white pennant with a red flag denotes that the storm-centre has passed; the red pennant with a red flag denotes that the storm-centre is approaching; while two red flags together are used when a very dangerous storm or hurricane is expected. In Canada, on the other hand, the storm signals consist of a cone and drum; the cone alone is used for an ordinary gale, and the drum and cone together for a heavy gale.

In Japan a red ball, red drum, and red cone are used, the ball denoting that stormy winds or gales are expected, the drum that a storm of rain or snow is expected, and the cone that a cyclonic storm of dangerous intensity is expected.

In China, at Shanghai, a drum, ball, cone, and diamond are used as storm-signals, and at Hong-kong a drum, ball, cone, and black cross.

Stornoway, a seaport and important fishery-station in Lewis, the chief town of the Outer Hebrides, near the head of a spacious sea-loch, 59 miles N. by W. of Portree in Skye and 180 of Oban. The principal feature is Stornoway Castle, completed in 1870 by Sir James Matheson (1796–1878). A tower 85 feet high commemorates the Great War. Pop. 4000.

Storting (from *stor*, 'great,' and *thing*, 'court'), the legislative assembly of Norway (q.v.). See also THING.

Story, JOSEPH, an American jurist, was born at Marblehead, Massachusetts, September 18, 1779, graduated at Harvard in 1798, and was admitted to the bar in 1801. He was elected to the state legislature in 1805, and there became a leader of the Republican (Democratic) party. In 1808 he was returned to congress, and in 1811 he was appointed by Madison associate justice of the Supreme Court of the United States, a place he filled with great credit for thirty-four years. In 1829 he became law professor at Harvard, and quickly raised the school to fame and prosperity. Of his many works the most valuable are his *Commentaries on the Constitution of the United States* (1833), on *The Conflict of Laws* (1834), and on *Equity Jurisprudence* (1835–36), which have passed through many editions. His legal writings and decisions are among those oftenest quoted in the higher courts of law. He died September 10, 1845. See the Life by his son (1851), who also prepared an enlarged edition of his *Miscellaneous Writings* (1851).—The son, WILLIAM WETMORE

STORY, was born at Salem 12th February 1819, graduated at Harvard in 1838, studied law under his father, and was admitted to the bar. He even entered with spirit on his profession; but soon (1848) the bias towards poetry and art, which had been checked in the father after one lackless venture, drew him to Italy and made him a sculptor. His productions in this field are numerous and of high excellence; and his writings include *Poms* (1847-56-86), *Roba di Roma* (1862), the *Tragedy of Nero* (1875), *Castle St Angelo* (1877), *He and She* (1883), *Fiumetta* (1885), and *Excursions in Art and Letters* (1891). Story, who died at Vallombrosa, 7th October 1895, had received distinctions from the French and Italian governments. See James, *W. W. Story and his Friends* (1903).

Stothard, THOMAS, designer and painter, was the son of a London innkeeper, who kept the *Black Horse* in Long Acre, and was born there, 17th August 1755. He received a respectable education in different boarding-schools, and on his father's death, having shown a predilection for the use of the pencil, was bound apprentice to a pattern-drawer in the city, but was released from his engagement before the term of expiry, and betook himself to more artistic work. His first notable effort was a series of designs for the *Town and Country Magazine*, which was followed by his imaginative compositions for Bell's *British Poets* and the *Novelist's Magazine*. The popularity of these was so great that for many years his services were constantly in request by the leading publishers in London. His earliest pictures exhibited at the Royal Academy were 'The Holy Family' and 'Ajax defending the Body of Patroclus.' In 1791 he was chosen an associate, in 1794 a member, and in 1813 librarian of the Academy. He died 27th April 1834. Stothard was a most graceful and facile illustrator. Not less than 3000 of his designs have been engraved, including those to Boydell's *Shakespeare*, *The Pilgrim's Progress*, *Robinson Crusoe*, and Rogers' *Italy and Poems*. His paintings, although skilfully 'composed' and finely coloured, lack the originality and force that come from a study of nature. Perhaps the best known is his 'Canterbury Pilgrims,' engraved in 1817. See Coxhead's monograph (1906), and the *Life* (1851) by Mrs Bray (q.v.), the widow of his son, CHARLES ALFRED STOTHARD (1786-1821), who acquired a great reputation as an antiquarian draughtsman.

Stoughton, JOHN, a learned English divine, was born in Norwich, 18th November 1807, and educated at Highbury College, Islington, and University College, London. Appointed Congregationalist minister at Windsor in 1832, he removed to Kensington in 1843, and here laboured till his retirement in 1875, when the congregation presented him with £3000. From 1872 till 1884 he acted as professor of Historical Theology and Homiletics in New College, St John's Wood. He was Congregational lecturer in 1855, chairman of the Congregational Union in 1856, received the D.D. degree from Edinburgh in 1869, took part in the Evangelical Alliance Conferences at New York (1873) and Basel (1879). He died 24th October 1897. See *Life* by his daughter (1899).

He edited for many years *The Evangelical Magazine*, and has written many books marked by profound learning, the most important *Church and State Two Hundred Years Ago* (1862); *Ecclesiastical History of England* (5 vols. 1867-74), supplemented by two volumes on the Reign of Anne and the Georges (1878), and two on the period of 1800-50 (1884); *Homes and Haunts of Luther* (1875); *Footsteps of the Italian Reformers* (1881); *Spanish Reformers* (1883); studies of Wilberforce, Penn, Howard; and *Recollections of a Long Life* (1894).

Stour, a river 47 miles long, flowing eastward along the Suffolk and Essex boundary to the sea at Harwich.

Stourbridge, a municipal borough (since 1914) of Worcestershire, on the Stour, at the border of Staffordshire and the Black Country, 12 miles W. of Birmingham. The famous Fireclay (q.v.) is said to have been discovered about 1557 by wandering glassmakers from Lorraine. Stourbridge now has earthenware and firebrick works, besides manufactures of iron, chains, shipping appliances, and heating apparatus, while important glass-factories are in the neighbourhood. The grammar school (1552), which Samuel Johnson attended, was rebuilt in 1862, since then has been much extended. The church of St Mary (1862) has a good 14th-century tower. Stourbridge has a corn exchange (1854), county court (1864), and a public library (1905), which also houses a school of art. Pop. (1851) 7847; (1921) 18,023.

Stourbridge Fair, Cambridge. See FAIRS.

Stourport, a town of Worcestershire, at the Stour's influx to the Severn, and the terminus of the Staffordshire and Worcestershire Canal, 14 miles by rail N. by W. of Worcester, and 4 SSW. of Kidderminster. Dating from 1770, it is a clean, neat place, with manufactures of carpets, iron, glass, &c. Pop. 5000.

Stouthrief, in the law of Scotland, means robbery committed in a dwelling-house.

Stove. See WARMING.

Stove-plants is another name for hothouse plants—plants which require artificial heat to make them grow and keep healthy in the colder temperate climes. They may be practically classified according to the kind and degree of heat required—from those suitable to the dry hothouse to those fitted to thrive in a cool greenhouse; from tropical orchids to hardy heaths. See PLANT-HOUSES, and the articles on the several species of plants.

Stow, JOHN, one of the earliest and most diligent collectors of English antiquities, was born in London in the year 1525. He was brought up to his father's trade of a tailor in Cornhill, but about his fortieth year abandoned it for antiquarian pursuits with a noble devotion which ought to have ensured him an old age of ease and honour, but which brought him instead only want and beggary. In his eightieth year he was rewarded with letters-patent from James I. authorising him to become a mendicant, or, as it is expressed, 'to collect amongst our loving subjects their voluntary contributions and kind gratuities.' He died 5th April 1605, and was buried in the parish church of St Andrew Undershaft, where his monument of terra-cotta, erected at the expense of his widow, may still be seen. Stow's reverence for the institutions of the past caused him to be suspected of a secret leaning toward popery. The principal works of Stow are his *Summary of English Chronicles*, first published in 1565, and subsequently reprinted every two or three years, with a continuation to the date of each new publication; *Annals, or a General Chronicle of England* (1580); and, most important of all, the *Survey of London and Westminster* (1598; ed. Kingsford, 1908), an account of the history and antiquities of the two cities for six centuries, together with their municipal institutions and forms of government. Besides these original works Stow assisted in the continuation of Holinshed's Chronicle, Speght's edition of Chaucer, &c. His invaluable *Memoranda to Three Fifteenth Century Chronicles* was printed with the text of these by James Gairdner for the Camden Society in 1881. There is a memoir prefixed to these

compendious edition of the *Survey* (1842) by W. J. Thoms.

Stowe, HARRIET BEECHER. See BEECHER.

Stowe House. See BUCKINGHAM.

Stowell, WILLIAM SCOTT, LORD, the eldest brother of Lord Eldon (q.v.), was born at Heworth, Durham, 17th October 1745. He was educated at Newcastle, went to Oxford in 1761, and became a college tutor. In 1779 he took the degree of D.C.L., removed to London, and was called to the bar in 1780. Dr Johnson introduced him to the Literary Club. As a barrister at Doctors' Commons he obtained a large practice, and his promotion was rapid. In 1788 he was appointed judge in the Consistory Court, knighted, and nominated a privy-councillor. In 1798 he became judge of the Court of Admiralty. Both as an ecclesiastical and admiralty judge he won high distinction. He wrote no systematic treatise or text-book, but his judgments were admirably reported, and supply the best evidence of his extensive legal learning, his sagacity, and his great literary ability. He was long the highest English authority on the law of nations. He represented Oxford in the House of Commons for twenty years, but he took no part in the business of parliament, although, like his brother, he was a zealous supporter of the Conservative party and the established church. At the coronation of George IV. he was raised to the peerage under the title of Baron Stowell of Stowell Park. In 1828 he retired from the bench, and on the 28th January 1836 he died. See the lives of the two brothers by Surtees (1846) and the Life by Roscoe (1916).

Stowmarket, a market-town of Suffolk, on the Gipping, 12 miles NW. of Ipswich. Pop. of urban district, 4200. Its fine flint-work church (chiefly Decorated) is surmounted by a tower and spire 120 feet high, and the interior contains some interesting monuments, amongst them one to Dr Young—Milton's tutor, and a former vicar. An iron-foundry, chemical and gun-cotton works are in operation, whilst malting and stay-making are also carried on. Burdett (the commentator) and the poet Crabbe were educated in the town, which, too, was the scene of Godwin's ministry (1778-87). See Hollingsworth, *History of Stowmarket* (1844).

Strabane, a market town of County Tyrone, Ireland, on the Mourne, 14 miles by rail S. by W. of Londonderry. Its flax and grain markets are celebrated; and it has fine Catholic, Episcopalian, and Presbyterian churches, and a convent on the hill above the town. Pop. 5000.

Strabismus. See SQUINTING.

Strabo, an ancient geographer, born at Amasia in Pontus, probably about 64 B.C., although some authorities make it ten years later. By the mother's side he was of Greek descent, and also closely connected with the Mithridatidae; of his father's family nothing is known. How the name Strabo ('squinny-eyed') must have originated is obvious, but whether any of the family were so called before him is uncertain. Strabo studied under the grammarian Tyrannion at Rome, under Aristodemus at Nysa in Caria, and under the philosopher Xenarchus either at Rome or at Alexandria. He does not appear to have followed any calling, but to have spent his life in travel and study, from which it may safely be inferred that he was well off. He was at Corinth in 29 B.C., ascended the Nile with Julius Gallus in 24, and seems to have been settled at Rome after 14 A.D., but all we know of the date of his death is that it was after 21 A.D. Of Strabo's great historical work in forty-seven books—from the fifth a continuation to his

own time of Polybius—we have only a few fragments; but his *Geographica* in seventeen books has come down to us almost complete. It is a work of great value in those parts especially which record the results of his own extensive observation. 'Westwards,' he says in a passage in the second book, 'I have travelled from Armenia to the parts of Thyrrenia adjacent to Sardinia; towards the south, from the Euxine to the borders of Ethiopia. And perhaps there is not one among those who have written geographies who has visited more places than I have between these limits.' Yet it must not be supposed that he describes with equal accuracy or fullness all the countries of whose geography he treats. Some he seems to have visited hurriedly, or in passing elsewhere; others he knows like a native. For example, his accounts of Greece, particularly the Peloponnesus, are meagre in the extreme, and of many of the obscurer regions he writes chiefly from hearsay. He makes copious use of his predecessors Eratosthenes, Artemidorus, Polybius, Posidonius, Aristotle, Theopompus, Thucydides, Aristobolus, and many other writers now lost to us, but he strangely depreciates the authority of Herodotus, and quotes few Roman writers except Fabius Pictor and Julius Caesar. Of the seventeen books of the *Geography* books i.-ii. contain a criticism of former geographers, and the mathematical part of physical geography—the poorest portion of the work; book iii. is devoted to Spain; iv. to Gaul, Britain, and Ireland; v. and vi. to Italy; vii. to the north and east of Europe as far as the Danube; viii.-x. to Greece; xi.-xvi. to Asia; xvii. to Africa. The style is pure and simple. The *editio princeps* of Strabo appeared at Venice in 1516. Good editions are those by Müller and Dübner (1853-56) and Meineke (1852-53). The Loeb Library includes a text and translation by H. L. Jones (1917 *et seq.*). Sir Walter Leaf edited the portions dealing with the Troad (1924).

Strabo, WALAFRID. See GLOSS.

Strachey, GILES LYTTON, author, was born on 1st March 1880 and educated at Trinity College, Cambridge. His *Eminent Victorians* (1918) with its crisp and incisive portraits, set a new style in biography, and was followed by the still more masterly study, *Queen Victoria* (1921). Other works of his are *Landmarks in French Literature* (1912), *Books and Characters* (1922), *Pope* (1925).

Strada, FAMILIANUS (1572-1649), Jesuit rhetorician, born in Rome, taught in the Gregorian College there, and wrote *De Bello Belgico* (2 vols. 1632-47) and *Profusiones Academicæ* (1617). The latter contains imitations of the styles of different poets, whereof that of Claudian has been translated into English by Ford the dramatist, by William Strode, and by Crashaw.

Stradella, ALESSANDRO, singer and composer, famous both in respect of his music and of his own fabulous history. His works, which consist of operas, airs, duets, cantatas, madrigals, sonatas, and oratorios, of which *San Giovanni Battista* is the best known, contributed to form the taste of such composers as Purcell and Scarlatti. The dates of his life are altogether uncertain; it can only be affirmed that he lived during the second half of the 17th century. He did not write *Pietà Signore*. According to an exploded story, Stradella, who was renowned for his exquisite voice and polished manner, was engaged by a wealthy Venetian to instruct his mistress in singing. But master and pupil became infatuated with one another and fled to Rome. They were traced thither by two bravos despatched by the Venetian; but both assassins, it is said, were so captivated with the music of Stradella's oratorio, which they heard him

conducting whilst lying in wait for him, that they abandoned their object, after betraying to him the plot. Stradella and the lady then fled to Turin. They were found there, and he was attacked and grievously wounded. He recovered and married the lady, and then passed to Genoa (1678). The day after both he and his wife were mortally stabbed by the emissaries of their unrelenting persecutor.

Stradivari, ANTONIO (1644-1737), of Cremona, a pupil of Nicholas Amati, carried the Cremona type of violin to its highest perfection. See VIOLIN; by Honore Petherick (1900); and monograph by W. H. A. F., and A. E. Hill (1902).

Strafford, THOMAS WENTWORTH, EARL OF, English statesman, was born on Good Friday, 13th April 1593, in Chaucey Lane, London, at the house of his mother's father, Robert Atkinson, a butcher of Lincoln's Inn. The eldest of the twelve children of Sir William Wentworth, he represented a great Yorkshire family, which from before the Conquest had been seated at Wentworth-Woodhouse near Rotherham, and was allied to royalty itself. He grew up a keen sportsman, an apt and diligent scholar, and was sent at an early age to St John's College, Cambridge. In 1611 he was knighted and married; and having thereafter travelled for fourteen months in France and Italy, in 1614 he was returned to parliament for the county of York, and succeeded his father in the baronetcy and an estate of £6000 a year. In 1615 he became *custos rotulorum* for the West Riding—a post from which Buckingham sought two years later to oust him; else we know little about him during James I.'s reign save as a generally silent member in three brief parliaments, a strenuous student, and a frequent attendant at the Court of Star-chamber. His first wife, Lady Margaret Clifford, eldest daughter of the Earl of Cumberland, died childless in 1622, and in 1625 he married Lady Arabella Holles, the younger daughter of Lord Clare.

Conscious of his own splendid abilities, and with no great belief in parliamentary wisdom, loyal in his devotion to crown and church, an eager advocate of domestic reforms, and therefore opposed to all wars of aggression, Wentworth in Charles's first parliament (1625) acted with, yet was not of, the opposition; from the second he was purposely excluded by his appointment to be sheriff of Yorkshire. In the July of that same year (1626), after a vain application to Buckingham for the presidency of the Council of the North, he was curtly dismissed from the keepership of the rolls, and for refusing to pay the forced loan he was committed first to the Marshalsea and then to an easy captivity at Dartford. So in the famous third parliament (1628) he impetuously headed the onslaught, not on the king, but on his evil ministers, and pledged himself 'to vindicate—what? New things? No! our ancient, sober, and vital liberties! by reinforcing of the ancient laws made by our ancestors; by setting such a stamp upon them as no licentious spirit shall dare hereafter to enter upon them.' From its meeting on 17th March until 5th May he was the leader of the Lower House; on 7th July the Petition of Right (q.v.), superseding a similar measure of his own, became law; and on the 22d he was created Baron Wentworth, on 10th December Viscount Wentworth, and on the 15th President of the North. As such at York he set himself to govern, to strengthen government with an efficient militia and ample revenue, and to 'comply with that public and common protection which good kings afford their good people.' Towards these ends he used on occasion high-handed methods, which embroiled him, however, chiefly with the gentry. His second wife died in October 1631, leaving a son William,

second Earl of Strafford (1628-95, died *s.p.*), and two daughters; and within a twelvemonth he married privately Elizabeth, daughter of Sir George Rhodes, knight.

In January 1632 he was appointed Lord Deputy of Ireland, but it was not till the July of the following year that he landed at Dublin. His plans had, however, been meanwhile carefully matured; and with the subtlety of a Machiavel and the strength of an Englishman he straightway proceeded to coerce Ireland into a state of obedience and well-being unknown alike before and afterwards. He raised the revenue from an annual deficit of £14,000 to a surplus of £60,000, and the customs from £12,000 to £40,000; transformed the army from a rabble of 1300 to an orderly force of 8000; swept the seas of the corsairs infesting them; introduced the cultivation of flax, still Ireland's one flourishing industry; called into existence a docile parliament; did his utmost to cleanse the Anglican stable of the Protestant Church; and, whilst seeking 'to draw Ireland into conformity of religion with England,' could yet boast truly that since he had 'the honour to be employed there, no hair of any man's head was touched for the free exercise of his conscience.' The aim of his policy (he and Land called it 'Thorough') was to make his master 'the most absolute prince in Christendom'; and 'the choice for Ireland in the 17th century did not lie between absolutism and parliamentary control, but between absolutism and anarchy.' The words are Professor Gardiner's, and he adds that 'if Wentworth be taken at his worst, it is hardly possible to doubt that Ireland would have been better off if his sway had been prolonged for twenty years longer than it was.' Wentworth taken at his worst should be Macaulay's Wentworth—the killer of his first wife, the debaucher of women, the 'wicked earl,' the 'first Englishman to whom a peerage was a sacrament of infamy,' the 'lost Archangel, the Satan of the apostasy,' who from the time of that apostasy received, like fallen Lucifer, a fresh name, Strafford. By this last amazing blunder Macaulay's carelessness may be fairly ganged, the falsity of his first two charges estimated; yet by Macaulay's verdict Wentworth was too long condemned. His only apostasy was his breaking with the parliamentary party when he realised and disapproved their puritanism and their design to grasp the executive power. In Wentworth's own correspondence are revealed his tenderness for his family, his love of harmless amusements, his hatred of gaming and drunkenness, his contempt of courtiers, and the maladies which constantly beset him—fever, ague, gout, and the stone—and to which his choleric temper is largely ascribable. He was not other-wise faultless, though many of his errors—e.g. in the matter of monopolies and of the proposed plantation of Connaught—were errors of the age. He was too masterful and self-reliant, too heedless of the means towards his end, intolerant of opposition to his will. One instance of his methods must suffice. Lord Mountnorris, vice-treasurer of Ireland, was for words rashly spoken court-martialed, and sentenced to death. The sentence was never meant to be carried out; in fact, Wentworth added, 'I would rather lose my hand than you should lose your head,' and Mountnorris was simply stripped of his offices. He deserved to be stripped of them; still, this was not the way to get rid of an opponent.

Till February 1637 Charles seems never to have applied to Wentworth on questions of general policy, and then, when he sought his approval of a foreign war, he was met with dissuasion. Nor till September 1639 did Wentworth become the king's principal adviser, the mark of the royal

favour being his elevation to the earldom of Strafford and the dignity of Lord-lieutenant of Ireland (January 1640). In August he was appointed Captain-general of the army in Ireland, and of an English army to be sent to Scotland. He recommended active measures, many of them of the strongest—the masterful habit had grown on him in Ireland, and he had failed to recognise a change of temper in the English people. The rebellion, provoked in Scotland by Charles's un wisdom, had spread to England. He hastened to Ireland to raise money and troops for Charles, but it was all too late. His Irish parliament was all subserviency, but a week after the meeting of the Long Parliament in November he was impeached of high-treason and lodged in the Tower. In the great trial by his peers, which opened in Westminster Hall on 22d March 1641, Strafford, broken though he was by sickness, defended himself with a fortitude and ability that moved even his accusers. The twenty-eight charges, covering 200 folios, at most amounted to 'emulative treason.' The first was his having 'traitorously endeavoured to subvert the laws and government of the realms of England and Ireland, and instead thereof to introduce an arbitrary and tyrannical government against law.' The gravest charge—his having in a committee of the Privy Council advised the king that 'he had an army in Ireland which he could employ to reduce *this kingdom*' (query England or Scotland)—was supported by only one witness, his personal enemy, Vane. The spirit of the Commons was shown in St John's declaration that 'we give law to hares and deer, as beasts of chase, but knock foxes and wolves on the head as they can be found, because they be beasts of prey.' As the charges against him did not constitute treason as defined by the statute of Edward III., on 10th April the 'inflexibles'—Pym and Hampden were not of their number—dropped the impeachment for a bill of attainder, declaring that treason which could not be proved to be treason. His doom was sealed when it was discovered that Charles, while scheming to gain over the leaders in parliament, was also plotting to rescue him by force. The bill passed a third reading by 204 votes to 59 in the Lower House, by 26 to 19 in the Upper ('Stone dead hath no fellow,' said Essex); and on 10th May it received the royal assent. Strafford had written to Charles releasing him from his reiterated pledge that he should not suffer in life or honour or fortune; and Charles at last accepted the release. 'Put not your trust in princes'—the cry was wrong from Strafford; then he prepared for death. They would not let him see his old friend Laud; but he knelt for his blessing under the prison window as he passed to the scaffold. He died on Tower Hill, 12th May 1641, and was buried at Wentworth-Woodhouse.

When he found his choice lay between helping the Commons to muster the king or the king to master the Commons, he had never hesitated to espouse the king's quarrel with all his might. But no doubt he sincerely believed that the well-being of England lay in government by the king rather than by the parliament, and in extending the power of the executive.

We know Strafford better now than his contemporaries could possibly know him, through his *Letters and Correspondence*, edited by Knowler (2 vols. 1739), and *Whitaker's Life and Correspondence of Sir George Radcliffe* (1810). Radcliffe (1593-1657) for years was Strafford's confidant; and his brief 'Essay towards the Life of my Lord Strafford,' appended to Knowler's work, is one of our chief authorities. Modern Lives are by John Forster (*Ennin. Brit. Statesmen*, vol. ii. 1836); Dr Furnivall in *Berdoe's Browning's Cyc.* asserted that this was completed 'on his own lines' by Robert Browning, and as Browning's it was edited for the Browning Soc. by C. H. Firth in 1892; J. B. Mozley (*Essays Hist.*

and Theological, 2d ed. 1884), Elizabeth Cooper (2 vols. 1874), and H. D. Traill (1889). See also the articles CHARLES I. and LAUD, with works there cited; Gardiner's *History of England*, and his article in *Dict. Nat. Biog.*; Browning's strangely unhistorical *Strafford: a Tragedy* (1837; ed. by Miss Hickey and Prof. S. R. Gardiner, 1884); and John Smith's *Catalogue Raisonné of the Works of Dutch Painters* (vol. iii. 1831) for a list of the half-dozen portraits by Van Dyck, in which the 'lion-faced' earl still lives for us.

Strain and Stress. A strain is any change of form or bulk of a portion of matter either solid or fluid. The system of forces which sustains the strain is called the stress. When a body is so strained that parallel lines remain parallel lines and parallel planes remain parallel planes, the strain is said to be homogeneous. Any cubical portion becomes a parallelepiped with angles, in general, other than right angles; and any spherical portion becomes an ellipsoid. The principal axes of this ellipsoid were originally mutually perpendicular diameters of the sphere. Clearly one of them must be the direction of greatest elongation (or least contraction), and another must be the direction of least elongation (or greatest contraction). These directions are the principal axes of the strain. A special case of the homogeneous strain is the isotropic strain, in which all lines suffer equal elongations—i.e. unit-length in any direction changes by the same amount. Here there is simple change of volume without any distortion; and the associated stress is of the type of a hydrostatic pressure. Now the most general homogeneous strain involves distortion as well as change of volume. If the strain is small we may decompose the complete strain into these two types of strain, which, as explained under Elasticity (q.v.), have to do with two quite distinct coefficients—viz. the Rigidity (q.v.) and the bulk modulus (see COMPRESSIBILITY). A distortion is a strain which involves no change of volume; and any distortion can always be decomposed into a number of shears or simple distortions. The simplest representation of a shear is given by the slight deformation of a circle into an ellipse of the same area. The major and minor axes of the ellipse are the principle axes of the shear, which is completely determined when its plane, axes, and elongations or contractions along these axes are given. A shear may also be represented by the sliding action of layer over layer which transforms a square into a parallelogram of the same area. Corresponding to a shear is the shearing stress, whose ratio to the shear is called the rigidity. It is obvious that in bending a bow or twisting a rod (see TORSION) we are producing strains which are not homogeneous; but by considering very small portions we are able to discuss the relations holding between the strains and corresponding stresses as if the strains were homogeneous.

When a body is perfectly elastic the relation between stress and strain is unchanging; in other words, to sustain the strain the same stress must be constantly applied. All solids, however, may be strained to such a degree that the strain may be supported by a weaker stress than that which produced the strain at first. Or, when a given stress is kept applied, the body may gradually alter its condition of strain as time goes on. Solids, in short, are found to possess Viscosity (q.v.), in virtue of which they yield slowly to a steady stress. Thus Tresca has caused metals to flow through ducts by application of great pressure. See STRENGTH OF MATERIALS.

Bodies may be strained by the action of other agents than mechanical forces. The most familiar example of this is the change of bulk which accompanies change of Temperature (q.v.). Electrification also produces changes of volume. Again, the mag-

netic metals, iron, nickel, and cobalt, undergo very complicated strains when magnetised in various ways. In all these instances there is always a reciprocal effect, a particular straining producing thermal, electric, or magnetic changes.

Straits Settlements, consisting then of three settlements on the coast of the Malay Peninsula and in the adjacent small islands of the Straits of Malacca, formerly under the Indian government, became a British crown colony in 1867. The capital is Singapore. The settlements, Singapore, Malacca, and Penang (including its dependencies, Province Wellesley and the Dindings), are separately dealt with. In 1886 the Cocos or Keeling Islands in the Indian Ocean were transferred from the government of Ceylon to that of the Straits Settlements, as was Christmas Island in 1889. The latter was made part of the settlement of Singapore in 1900, the former in 1903. In 1906-7 the island of Labuan, off the north west coast of Borneo, passed from the administration of the British North Borneo Company to that of the colony, and in 1912 became a settlement. For particulars of these, see the respective articles. The total area is 1000 sq. m., and the total pop. (1881) 423,384; (1911) 714,069; (1921) 883,769. In 1918 275,000 were Malays, 433,000 Chinese, and 94,000 natives of India. Singapore is the seat of government. The government of the colony is in the hands of a governor and executive and legislative councils, the former wholly official, the latter partly official and partly nominated. Each settlement has a municipal board, the members being appointed by the governor. The governor is also high commissioner for the Federated Malay States and for Brunei, and British agent for British North Borneo and Sarawak. The principal productions of the colony are tin, gambier, tapioca, rice, rubber, sugar, pepper and other spices, hides, and rattans.

Stralsund, a seaport of Prussia, is situated on a narrow strait called the Strela Sound, which divides the mainland from the island of Rugen. Down to 1873 the place was a fortress of the first class. Many of the houses are finely gabled, which gives the town a quaint and ancient look. The most interesting building is the town-house (1306), with a museum of antiquities from the island of Rugen. Stralsund carries on a large export trade in sugar and grain, and manufactures cement, mineral waters, lacquer, machinery, safes, iron castings, electric lamps, soap, furniture, and playing-cards. Pop. (1925) 39,404. Stralsund was founded in 1209, and became one of the most important members of the Hanse. During the Thirty Years' War it successfully withstood a terrible siege (1628) by Wallenstein; but in 1678 it capitulated to the Great Elector after a furious bombardment. It again opened its gates to Prussia and her allies in 1715, to the French in 1807, and to the Danes and others in 1809. The town was held by the Swedes from 1628 to 1814; in the year following (1815) Denmark gave it up to Prussia.

Stramonium. See THORN-APPLE.

Strange, SIR ROBERT, engraver, was born at Kirkwall, in Orkney, on 14th July 1721. He had tried sailing and a law-clerkship with an elder half-brother in Edinburgh, when in 1735 he was apprenticed for six years to an English engraver there, Richard Cooper. His apprenticeship ended, he fell in love with a young Jacobite lady, Isabella Lumisden, and for her sake in 1745 espoused the cause of Prince Charles Edward, engraving not only his portrait but his bank-notes, and enlisting as a private in the prince's life-guards. He fought at Culloden, escaped his pursuers by hiding beneath his sweetheart's ample-hooped gown, in

1747 married her, and next year repaired to Rouen and thence to Paris, and studied under Deschamps and Lebas. In 1750 he returned to Britain, and settling in London soon attained the very highest rank in his profession. On a second visit to the Continent (1760-65), to execute engravings after the old masters, his eminence was recognised by the academies of Paris, Rome, Florence, Bologna, and Parma, which all conferred on him the honour of membership; and subsequently, in 1787, he was knighted, having made peace with the reigning house by engraving West's picture of the apotheosis of George III.'s children, Octavins and Alfred. He died a wealthy man on 5th July 1792, his wife surviving him by fourteen years.

See Dennistoun's *Memoirs of Sir Robert Strange* (2 vols. 1855); the Life by the Rev. F. Woodward prefixed to *Twenty Masterpieces of Strange* (1871); and also the Introduction to Marshal Keith's *Memoir* (Spalding Club, 1843).

Strangford, VISCOUNT. Percy-Clinton-Sydney Smythe was born 31st August 1780, studied at Trinity College, Dublin, and entered the diplomatic service. He succeeded to the title as sixth viscount in 1801, was secretary of legation at Lisbon, and later ambassador successively to Portugal, Sweden, Turkey, and Russia. He was raised to the English peerage as Baron Penshurst in 1825, and died 29th May 1855. His translation of the *Rimas* of Camoens he published in 1803.—His youngest son, PERCY-ELLEN-FREDERICK-WILLIAM SMYTHE, was born at St Petersburg, 26th November 1825, and had his education at Harrow and Merton College, Oxford. He entered the diplomatic service, early acquired an unexampled command of languages, and served as Oriental secretary during the Crimean war. In 1857 he returned home to succeed as eighth and last viscount, thereafter lived mostly in London, immersed in philological studies ranging from Turkish, Persian, Arabic, and Afghan to Basque, Celtic, and Lithuanian, and died there, 9th January 1899. In spite of his phenomenal acquirements, he wrote little more than a few *Saturday, Pall Mall*, and *Quarterly* articles. His *Selected Writings: Political, Geographical, and Social*, was edited by his widow (2 vols. 1869), who also published his *Letters and Papers upon Philological and Kindred Subjects* (1878). See Fonblanque's *Lives of the Lords Strangford* (1878).

Strangles is a contagious eruptive disease of the horse, most common in young animals. It is ushered in by sore throat and cough, a mucopurulent nasal discharge, and the formation of an abscess in the space between the branches of the lower jaw. In a few days the abscess comes to a head, bursts, and in favourable cases the patient is soon well again. From exposure to cold, poverty, or other causes, the swelling, however, occasionally appears in less favourable situations, as about the glands lying within the shoulder, in those of the groin, or even internally in those of the mesentery. Such irregular cases are apt to be protracted, accompanied by much weakness, and often prove fatal. Bleeding, physic, and irritant dressings are injurious. Good food and nursing, with fomentations to the throat and steaming of the head, favour the healthier maturation of the swelling. When there is debility, coax the animal to eat by offering him at short intervals small quantities of scalded oats, malt, bran, or green food, and allow him several times daily a pint of sound ale if he will drink it, but do not force it upon him, as the throat is often irritable and the animal might be choked. Keep isolated, to prevent the communication of the disease to other animals, and disinfect the loose-box after recovery.

Strangulation may be defined as an act of violence in which constriction is applied directly to the neck, either around it or in the forepart, in such a way as to destroy life. This definition obviously includes hanging, which differs from other forms of strangulation only in that the body is suspended. The direct cause of death in the great majority of cases is arrest of the respiration owing to pressure on the windpipe—i.e. asphyxia. If much violence is used, it may be produced by direct injury to the upper part of the spinal cord from fracture or dislocation of the cervical vertebrae (as is now the rule in execution by hanging), or by syncope from shock, and in such cases must be almost instantaneous. On the other hand, if the constriction is so applied as to compress the great vessels in the neck and not the windpipe, as may happen in 'garotting' it is due to coma, and is somewhat slower than in cases of asphyxia. Or if both vessels and windpipe are compressed, coma and asphyxia may both contribute to cause death.

The internal appearances of the body after death are those of Asphyxia (q.v.), with specially marked congestion of the brain; the most constant external appearances are congestion of the face, with prominence of the eyes and protrusion of the tongue, and marks on the neck corresponding to the cord or other constricting agent. The latter are most evident and the injuries to the neck most severe in homicidal cases. Death by hanging (excepting judicial executions) is almost always suicidal; by other forms of strangulation it also is frequently suicidal, but often homicidal. Accidental strangulation in any form is rare.

When suspension of the body has not continued for much more than five minutes, and the parts about the neck have not suffered violence, there is a probability that resuscitation may be established; although many cases are recorded when after only a few minutes' suspension it has been found impossible to restore life. Moreover, if a person who has hanged himself has been cut down sufficiently soon to allow of the respiratory process being restored, he is by no means safe; death often taking place from secondary effects at various periods after the accident. It is believed that unconsciousness comes on very rapidly, and death takes place without causing any suffering; the violent convulsions that are so often observed being similar to those which occur in epilepsy.

In homicidal cases, however, the appearance of the face sometimes indicates much distress. A man named Hornshaw, who was on three occasions resuscitated from hanging—a feat which he performed in London for the amusement of the public—stated that he lost his senses almost at once; and other persons who have been restored state that the only symptoms of which they were conscious were a ringing in the ears, a flash of light before the eyes, then darkness and oblivion. The treatment to be adopted after the patient has been cut down may be briefly summed up as follows: Exposure to a free current of air, cold affusion if the skin is warm, the application of ammonia to the nostrils, of mustard poultices to the chest and legs, and of hot water to the feet, and the subsequent abstraction of blood if there should be much cerebral congestion; above all, artificial respiration should be used if natural breathing do not at once commence. From the post-mortem appearances, together with circumstantial evidence, the medical practitioner is not unfrequently called upon to decide such questions as these: Was death caused by hanging, or was the body suspended after death? Was the strangulation the result of accident, homicide, or suicide? In case of strangulation from other causes than that of hanging the post-mortem symptoms are similar, but the injury

done to the parts about the neck is commonly greater. In manual strangulation the external marks of injury will be in front of the neck, about and below the larynx; and if death has been caused by a ligature the mark round the neck will be circular, whereas in hanging it is usually oblique. See Taylor's *Medical Jurisprudence*.

The term Strangulation is also applied to a dangerous complication which may arise in cases of Hernia (q.v.).

Strangury. See URINE.

Staunraer, a royal burgh and seaport of western Wiglowshire, beautifully situated at the head of Loch Ryan, 73 miles WSW. of Dumfries by rail. The buildings are a 16th-century castle in which the bloody Claverhouse lived as sheriff, the town-hall and court-house (1872-73), and several handsome churches. There are no manufactures, but considerable trade in farm-produce, two large creameries operating within the burgh. Loch Ryan affords fair fishing, including oysters. There is a considerable shipping-trade, and a commodious mail steamer plies daily between Staunraer and Larne in Ireland, the 'short-sea passage' merely taking about 24 hours, only half being in open channel. Pop. (1871) 5977; (1921) 6138. Till 1885 Staunraer returned one member with Wigtown (q.v.).

Straparola, GIOVAN FRANCESCO, was born near the end of the 15th century at Caravaggio, about half-way between Milan and Genoa. In 1550 he published at Venice *Tredecì piacevoli notti*, the second part at the same place in 1554. This famous work was a collection of stories in the style of the *Decameron*, grouped round an imaginary incident. Francesca Gonzaga, daughter of Ottaviano Sforza, Duke of Milan, on account of commitments in that city, retires to the island of Murano, near Venice, where, surrounded by a group of brilliant ladies and gentlemen, she passes the time listening to stories related by the company. Thirteen nights are thus spent, and seventy-four stories told, each followed by an enigma, when the approach of Lent brings an interruption. These stories are derived from the most various sources; twenty-four are borrowed from Jerome Morlini, fifteen from Boccaccio, Suchetti, Brevio, Ser Giovanni, the *Fabliaux*, the *Golden Legend*, and the *Romance of Merlin*. Six are of plain oriental origin, and may be found in the *Panchatantra*, *Forty Viziers*, *Siddhi Kâr*, and *Thousand and One Nights*. Twenty-nine stories remain, and of these twenty-two are genuine folk-tales. Two of Straparola's stories found a wider immortality in Perrault's 'Peau d'Âne' and 'Le Chat Botté,' and many of Madame d'Aulnoy's fairy-tales, as well as others in the *Cabinet des Fées*, are mere translations. Straparola's book passed through sixteen editions in twenty years; a French translation of the first book by Jean Louveau appeared in 1560, reprinted in 1573, along with the second book as translated by Pierre de Larivey (*Les Fucieuses Nuits de Straparole* in P. Jannet's 'Bibliothèque Elzevirienne,' 2 vols. 1857; new ed. of Jouaust, with preface by Gustave Brunet, 1882). Many of Straparola's stories are *factious* in its narrowest sense; but at least they are no worse than their contemporaries. The work was prohibited by the church in 1605; yet another reprint appeared at Venice so soon after as 1608.

See F. W. V. Schmidt's German translation of eighteen tales, with valuable notes (Berlin, 1817); the Dissertation by F. W. J. Brackmann (Göttingen, 1867); Liebrecht's translation of Dunlop's *History of Fiction* (1851); and the translation of the *Nights* by W. G. Waters (2 vols. 1894).

Strasbourg (Ger. *Strassburg*, Fr. *Strasbourg*), the capital of the French department of Bas-Rhin, in 1871-1919 capital of Alsace-Lorraine, stands on the

river Ill and the canals connecting the Rhine with the Rhone and the Marne, 2 miles from the left bank of the Rhine, on which it has a port (1891). The citadel, originally built by Vauban (1682-84), was demolished by the Germans during the bombardment of 1870, but they rebuilt it and strengthened the fortifications (demolished 1920) with some fourteen detached forts on the adjacent heights, so that Strasburg ranked as a first-class fortress of great strength. Its position near the borders of France, Germany, and Switzerland is favourable to its commerce, and gives it great strategic importance. The most celebrated building in the city is the cathedral or minster, founded in 1015 or in 1179, but principally built between 1277 and 1439; some of the oldest parts are Romanesque (portions of choir and transept), but the church as a whole is one of the sublimest specimens of Gothic architecture in existence. The principal architect (to whom most of the glorious western façade is due) was Erwin von Steinbach (fl. 1318). 'Only one of the two towers was completed, with a spire of open stone-work (1439); it is 466 feet high. The minster has a remarkable astronomical clock dating from 1838-42; in it are portions of an older one made in 1571, but there was a remarkable clock here in the 14th century. In the present one are, besides a complete planetarium and perpetual calendar, many automaton figures—angels which strike the quarters, twelve apostles which come forth at noon and pass in procession before a figure of Christ, and a cock which crows at stated times. In the church are also a magnificent rose-window (42 feet across), a fine pulpit, and grand stained glass. The damage done to the structure during the siege of 1870 was carefully repaired. Other notable buildings are the Protestant church of St Thomas, with the tomb of Marshal Saxe, the imperial palace, the library (formerly the castle, and then the episcopal palace), the new university, the public buildings of the province, and the arsenal. The university of Strasburg was the only French university besides Paris with the full complement of faculties. Founded in 1621, on the basis of the academy of Johannes Sturm (q.v.), it became specially famous in the branches of medicine and philology, but was broken up during the Revolution. In 1803 a Protestant academy was established with ten chairs; and five years later Napoleon founded an imperial academy with faculties of law, medicine, physical science, and philosophy; in 1819 a partial fusion of these academies took place. The university was reorganised as a German institution in 1872, is equipped with new buildings, magnificent laboratories, &c., and was again refounded as a French university in 1919. The famous library, with nearly 200,000 volumes and precious *Incunabula*, was entirely destroyed by fire during the bombardment in 1870, but was replaced by a new collection that had swelled to 1,200,000 volumes when Strasburg was given to France. The trade of Strasburg is very extensive, and it has a great variety of manufactures—beer, pâtés de foie gras, leather, cutlery, engines, musical instruments, jewellery, tobacco, furniture, chemicals, fancy articles, &c. Pop. (1880) 104,471; (1890) 123,566; (1900) 151,041; (1910) 178,913; (1921) 165,835.

Strasburg, the *Argentoratum* of the Romans, was colonised by them during the reign of Augustus. Here Julian won a great victory over the Allemanni in 357 A.D. The name *Stratisburgum* first appears in the 6th century. It became a free town of the German empire in the 13th century, and both then and in the early part of the 15th century occupied a prominent position in respect of culture and enlightenment. In 1681 it was seized by Louvois, at the command of Louis XIV., in a time

of profound peace, and was confirmed to him by the treaty of Ryswick, but retained the quaint appearance of a German imperial city. On September 28, 1870, after a siege of seven weeks, Strasburg surrendered to the Germans. With the rest of Alsace-Lorraine (q.v.) Strasburg passed to France in 1919.

Strata. See STRATUM.

Strata Florida (Latinised from Ystrad Fflur, Plain of the Fflur'), the ruins of a Cistercian abbey founded in 1164, 17 miles SE. of Aberystwyth. Little of the building but a Norman archway and part of a wall are now standing; but excavations in 1857-88 laid bare the foundations and some fine tiled pavements. See the monograph by S. W. Williams (1889).

Strategy has been defined by military writers as the 'science of generals,' 'the art of making war on the map,' or 'the art of rightly directing masses of troops towards the object of the campaign'; it is dependent upon the due consideration of everything that can possibly influence the campaign. Roughly speaking, strategy directs the movements of troops until contact with the enemy is imminent. From that moment all combinations and manoeuvres are classed as *Tactics* (q.v.), until perhaps the opposing armies become again sufficiently separated for strategy to be employed. The object of strategy is to bring an adversary into such a position that the chances of victory will be against him, and defeat will entail disasters beyond the loss of the battle. Strategy will be offensive or defensive according to political or geographical considerations and the relative strength or mobility of the belligerents. The former will give all the advantages of the initiative to the commander who can adopt it. He will by invading the enemy's country, consume his supplies, and spare his own the horrors of war. He will be able to make and carry out his plans with confidence, his opponent, ignorant of his positions and intentions and of his force on this or that line of advance, having to make guesses which may easily be quite erroneous. Defensive strategy, on the other hand, has advantages in facility of supply and transport, freedom of movement, and power to utilise obstacles. Both sides have to guard with care their lines of communications with their bases of operations, and in some campaigns the advancing assailant finds this a heavy tax on his numbers. But in a struggle like the Great War both belligerents so contrived to cover the whole front continuously, and to have their flanks so safe on neutral or other obstacles, that communications and bases could only be threatened by a break-through.

The best strategy aims continuously at the destruction of the enemy's chief armed force; that being achieved, he is at your mercy. The commander operates so that his force is in full strength at the decisive or any important battle, while trying by manoeuvres and deceptions to prevent the enemy having his full strength there. If his total force is larger than the other's, he will aim at an eventual outflanking whenever possible, on one or both wings, for this sort of envelopment often produces the most comprehensive result. The opponent's strategy will then be that of the *interior lines*, viz., an attempt by sudden massing in a particular direction to bring a local preponderance to bear, sufficient to effect quickly a serious breach. For both sides, even for the defender, the need is activity combined with secrecy, so that surprise may be achieved. Passivity, if too prolonged, is the road to defeat, for opportunity is being granted to the foe to act as suits him best. To lose freedom of movement is pernicious.

This short statement of principle applies in spirit both to earlier warfare, when there was plenty of room for manœuvre beyond flanks, and to the era of vast armies like those of the Great War, when there was in the chief theatres no open flank. Of the *interior line* system Napoleon was the great exponent, having in his earlier years of command often the inferior force; of the enveloping system von Moltke (1866 and 1870) gave the most striking examples, always outnumbering his enemy. When fronts developed into continuity, as in 1914 to 1918, the aim was, by secret massing and the use of a titanic bombardment, to effect a complete breach and thus to create artificially two flanks in the enemy's front. On a few occasions it nearly succeeded, but never quite.

See Hamley's *Operations of War* (1907); Napoleon's *Military Correspondence*; works by Marshal Foch; works by von Schlieffen; and *TACTICS*.

Stratford, a thriving town of Essex, on the Lea, 4 miles ENE. of London. It had a Cistercian abbey (1134) and the Empress Matilda's three-arched bow-shaped bridge (removed in 1839); it has a handsome town-hall (1869), and extensive manufactures. It is now included in the parliamentary and county borough of West Ham. On the other side of the Lea is the parish of Bow, or Stratford-le-Bow, now included in the London metropolitan borough of Poplar.

Stratford, a port of entry and capital of Perth county, Ontario, on the Avon, 88 miles by rail W. of Toronto, with railway-shops, woollen mills, and manufactories of machinery, farming implements, boots and shoes, &c. Pop. 13,000.

Stratford de Redcliffe, SIR STRATFORD CANNING, K.G., G.C.B., first Viscount, the famous ambassador, known as 'the Great Elchi,' was descended from the Cannings of Bristol, but was born in London, 4th November 1786, the fifth and youngest child of Stratford Canning, a merchant, and was first cousin to George Canning the statesman. He was educated at Eton, and proceeded in due course as scholar to King's College, Cambridge, where, however, his terms were interrupted by diplomatic appointments, and he did not take his degree till 1812, when it was granted by royal mandamus. In 1807 he acted as précis-writer to his cousin at the Foreign Office, and in the same year went as second secretary with Merry's mission to Copenhagen. In 1808 he was appointed first secretary to Sir Robert Adair's embassy to Constantinople, and succeeded him as minister-plenipotentiary in 1810. His duty was to counteract the influence of France at the Porte, and he succeeded on his own initiative and without the smallest countenance from his government or the Foreign Office in negotiating the important treaty of Bucharest in 1812 between Russia and Turkey, who were then at war, just in time to release the Russian army of the Danube and enable it to fall upon Napoleon on his retreat from Moscow. This signal service was recognised by Lord Castlereagh's government, who appointed him minister in Switzerland, 1814; there he assisted in framing the Swiss constitution, and visited Vienna as commissioner during the famous Congress of 1815. He resigned the mission in 1819, and was immediately appointed minister to the United States, and remained at Washington till 1823. In the following year he was sent on a special mission to Vienna and St Petersburg, connected with the Greek question, and in 1825 went to Constantinople as full ambassador. Here he witnessed the massacre of the Janizaries, and exerted himself on behalf of the insurgent Greeks. After the battle of Navarino the embassy was necessarily withdrawn, and, in consequence of serious differ-

ences with Lord Aberdeen on the policy to be adopted towards Greece, Canning resigned his post in 1828, but his services were recognised by the decoration of the Grand Cross of the Bath. In 1831 he was again sent to Constantinople on a special mission, to draw the boundaries of the new kingdom of Greece, and on his return was gazetted ambassador to St Petersburg; but the tsar, without alleging a reason, declined to receive him—probably because he dreaded so keen an eye at close quarters. In 1833 Sir Stratford went to Madrid on a special mission relating to the Portuguese succession, but his efforts were, as it was foreseen they must be, fruitless. During the intervals in his diplomatic career he sat in the House of Commons as a moderate Tory, or 'Stanleyite,' for Old Sarni, 1828-30; Stockbridge, 1831-32; and King's Lynn, 1834-42; but failed to make his mark as an orator or a debater. From 1842 to 1858 he was again ambassador at Constantinople, and built up that extraordinary influence so eloquently described by Kinglake, which gained him the name of the 'Great Elchi.' He induced the sultan to inaugurate a series of reforms, and to authorise numerous improvements in the condition of the Christian rayas, culminating in the celebrated Hatti-Humayun of 1856, which may be termed the Magna Carta of the Christian subjects of the Porte. His diplomatic skill and his unbounded influence over the Turks were never seen to greater advantage than in 1853, in his negotiations with Prince Menschikoff, the Russian special ambassador, concerning the dispute about the Holy Places and the Russian claim for predominating influence on behalf of the Christians of Turkey. His strenuous and unflinching exertions to preserve peace were, however, defeated by the obstinacy of the Tsar Nicholas and the vacillating weakness of Lord Aberdeen's government; the war which ensued between Russia and Turkey involved England and France; and the result was the expedition to the Crimea, and the siege of Sebastopol. At the close of the war, after obtaining the proclamation of the Charter of Reform, Lord Stratford, who had been created a viscount in 1852, resigned his embassy in 1858, at the age of seventy-one, and a diplomatic career of unexampled distinction, lasting over half a century, came to an end. Stratford de Redcliffe was the last of the old style of semi-royal and half-independent ambassadors: the telegraph-wire has made ministers of his mettle and character impossible if not superfluous. After his retirement he occasionally took part in the debates on foreign policy in the House of Lords, and devoted part of his leisure to the writing of poetry, which had been a favourite occupation with him since he wrote a fine poem on *Bonaparte*, which attracted the admiration of Byron, in 1814. Some articles on the *Eastern Question* were collected after his death and edited by Dean Stanley. He was created a Knight of the Garter in 1869 at Gladstone's recommendation, and died in the full enjoyment of his mental powers though at the great age of almost ninety-four, 14th August 1880. His tomb is at Frant, Sussex; but a statue was erected in Westminster Abbey in 1884.

See *Life of Stratford Canning, Viscount Stratford de Redcliffe*, by Stanley Lane-Poole (2 vols. 1888; 1 vol. 1890).

Stratford-upon-Avon, Shakespeare's birth-place, a municipal borough and market-town of Warwickshire, 8 miles SW. of Warwick, 22 SSE. of Birmingham, and 101 NW. of London. It stands on the right bank of the stately Avon (q.v.), which is here spanned by the 'great and sumptuous bridge' of fourteen pointed arches, 376 yards long, built by Sir Hugh Clopton, then the Lord Mayor of London, who died in 1496. The prosperity of the town depends on the thousands of

Shakespeare pilgrims. Shakespeare is over all 'Shakespeare's House' (where he was born in April 1564), in Henley Street, was purchased by the 'Trustees and Guardians of Shakespeare's Birthplace,' and became a national trust in 1847 being restored in 1858-59. Here is a museum containing the 'Stratford portrait,' and, on the wall of one of the rooms, the signatures of Byron, Scott, Tennyson, Thackeray, Dickens, &c. King Edward VI.'s grammar-school, where Shakespeare was educated, was founded by a priest named Thomas Jolyffe in 1482, and re-endowed by Edward VI. It occupies the second floor of the ancient guildhall, founded in 1296 by Robert de Stratford, and was restored in 1892. The 'New Place,' built by Sir Hugh Clopton in the reign of Henry VII., was purchased by Shakespeare as a residence in 1597. Here he died 23d April 1616. Here, too, Queen Henrietta Maria stayed in 1643. It (or rather its successor, 1702) was wantonly razed in 1759 by a vicar of Stratford, who also felled the poet's mulberry, beneath which Garrick was regaled in 1742. Its site (now a garden in which can still be traced the foundations of the house) became a national trust in 1861. Holy Trinity, a beautiful cruciform parish church, Early English to Perpendicular in style (having been built gradually between 1332 and 1500) contains, in the chancel, Shakespeare's grave and that of Anne Hathaway, his wife; the portrait bust (1616) by Gerard Janssen, the parish register (with the entries of Shakespeare's baptism and burial), and the American stained glass memorial window of the 'Seven Ages.' The Shakespeare Fountain (1887) was also erected by an American, G. W. Childs (q.v.). The Shakespeare Memorial building, consisting of a theatre, library, and picture gallery, was founded in 1875, and is situated close by the river. The theatre (connected with the rest of the building by a corridor bridge) was destroyed by fire 6th March 1926, the library and picture-gallery, with their contents, fortunately escaping serious damage. The theatre had been severely criticised architecturally, and was, moreover, too small for the Shakespeare Festival, which had been held there annually since 1879. A national fund was opened to build a new theatre. The library possesses some of the early quartos, the first four folios, and several other rare editions of Shakespeare's works; in the picture gallery are paintings by Romney, Lawrence, Reynolds, Opie, and others of the English school, and the original 'Droeshout' portrait. Houses associated with Shakespeare are Hall's Croft, the home of Shakespeare's son-in-law, Dr John Hall, and his wife Susanna; Nash's house (restored 1911-12), the home of Thomas Nash, first husband of Shakespeare's grand-daughter, Elizabeth Hall, now a museum and a national trust, in which are relics made from the wood of the famous mulberry; Quiney's house, the home of Thomas Quiney, a vintner, and his wife Judith (Shakespeare's younger daughter), the cellar of which used to be the town lock-up; and Shaw's house (Julius Shaw witnessed Shakespeare's will), now the Shakespeare Head press. Close to Stratford are Shottery, with Anne Hathaway's cottage (purchased for the nation in 1892 for £3000); Luddington, where tradition says they were married; Charlecote Hall, the seat of the Lucys; Clopton, with memories of the Gunpowder Plot; and Mary Arden's (Shakespeare's mother's) home at Willmote.

In Stratford itself there still remain to be noticed the chapel of the Guild of the Holy Cross (13th century); the chancel rebuilt about 1450, and the rest by Sir Hugh Clopton; the half-timbered houses, especially Harvard House (1596), so-called after John Harvard, who founded Harvard University, U.S.A., to which it now belongs; and the

town hall (1633, rebuilt 1768-1863) with Gainsborough's portrait of Garrick. Stratford was incorporated in 1553. Pop. (1921) 9392.

See 'Shakespeare's Birthplace, &c., Trust Act, 1891'; Wheeler's *History and Antiquities of Stratford-upon-Avon* (1806); works by J. O. Halliwell-Phillips (1853-85); Bloom's *Shakespeare's Church* (1902); Sir S. Lee's *Stratford-upon-Avon from the Earliest Times to the Death of Shakespeare* (1902); W. Salt's *Brassington's Shakespeare's Homeland* (1913); Dugdale Society's *Minutes and Accounts of the Corporation of Stratford-upon-Avon, and other Records*, vol. i. 1558-66 (1921), vol. ii. 1566-77 (1924), vol. iii. 1577-86 (1926); Patrick and Loscelles Abercrombie's *Stratford-upon-Avon: Report on Future Development* (prepared for Stratford-upon-Avon Preservation Committee in 1923); H. E. Forrest's *The Old Houses of Stratford-upon-Avon* (1925); and other works cited at SHAKESPEARE.

Strathaven, a town of Lanarkshire, 1 mile W. of Avon Water, and 16 miles SSE. of Glasgow. On the north side is the picturesque ruin of Avondale Castle, and 5 to 7 miles south-west are the battlefields of Drumclog and Loudoun Hill.

Strathelyde. In the 8th century the ancient confederacy of the Britons was broken up into the separate divisions of Wales and English and Scottish Cumbria. Scottish Cumbria, otherwise called Strathelyde, thenceforth formed a little kingdom, comprising the country between Clyde and Solway; governed by princes of its own, and having the fortress-town of Alchde or Dumbarton for its capital. Becoming dependent on Scotland (see BRETTES AND SCOTS), it was annexed to the Scottish crown at the death of Malcolm I., on failure of the line of native sovereigns. Edgar bequeathed Strathelyde to his youngest brother David, again separating it from the crown of Scotland, which went to his intermediate brother, Alexander I. David held it throughout Alexander's reign in spite of that king's opposition, and on Alexander's death without issue in 1124, it was permanently reunited to the Scottish kingdom under David I.

Strathcona, BARON (Donald Alexander Smith), born at Forres in 1820, entered the Hudson's Bay Company's service in 1838, and rose to be governor in 1889. He was special commissioner during the Red River rebellion in 1870, main promoter and director of the Canadian Pacific Railway, and held other important offices in the Dominion. In 1896 he was made High Commissioner for Canada in London. He was raised to the peerage in 1897. He died in 1914. There is a *Life* by Beckles Willson (1915).

Strathfieldsaye, a Hampshire estate 7 miles NNE. of Basingstoke, was purchased by parliament in 1817 and presented to the Duke of Wellington (q.v.).

Strathmore (Gael., 'Great Valley'), the most extensive plain in Scotland, is a low-lying tract extending north-eastward across the country from Dumbartonshire to Stonehaven in Kincardineshire, bounded on the north by the great mountain-rampart of the Highlands, and on the south by the Lennox, Ochil, and Sidlaw Hills. It is 100 miles long and from 5 to 10 miles broad; but Strathmore proper extends only from Perth to near Brechin about 40 miles).

Strathnairn, LORD, commander-in-chief in India. Hugh Rose, son of Sir George Rose, was born 1801, and entered the army in 1820. He was military attaché to the Turkish army in the war with Mehemet Ali in 1840, was consul-general for Syria, and as secretary to Lord Stratford de Redcliffe was *chargé d'affaires* at Constantinople in 1853-54. He was commissioner at the French headquarters during the Crimean war, and, now K.C.B., was sent to India in 1857 to command the Central Indian army, in command of this force he virtually reconquered

Central India; and, though his campaign was overshadowed by those of Sir Colin Campbell, it is generally admitted that the operations of Sir Hugh Rose were more brilliant and skilful than those of his chief. On the departure of Lord Clyde Sir Hugh Rose became commander-in-chief in India; in 1865-70 he held the same post in Ireland. Raised to the peerage in 1866, and made field-marshal in 1877, he died 16th October 1885. See Sir O. T. Burne, *Clyde and Strathnairn* (1891).

Strathpeffer, a fashionable Scottish watering-place in the county of Ross and Cromarty, to the south of Ben Wyvis (3429 feet), and 5 miles W. of Dingwall by rail, 215 NNW. of Edinburgh. Its sulphur and chalybeate springs are highly efficacious in digestive and rheumatic disorders; and it has a pump-room, baths, and large hotels.

Strathspey, a Scottish dance, allied to and danced alternately with the Reel (q.v.). The name is derived from the strath or valley of the Spey, where it seems to have originated; but it does not occur before the middle of the 18th century, and was at first applied indiscriminately to music now known as reels. It differs from the latter in being slower, and abounding in the jerky motion of dotted notes and semiquavers (when the latter precede the former it constitutes the *Scotch Snap*), while the reel is almost entirely in smooth, equal, gliding motion. Many of Burns's songs were written to the music of strathspeys.

Stratolites. See WATER-SOLDIER.

Stratum (Lat. 'spread out'), equivalent in Geology to the term *bed* or *layer*, but implying that the beds or layers of rock have been spread out over the surface. Rocks so arranged are said to be stratified. The stratified rocks include all those that are of derivative origin, such as conglomerate, sandstone, shale, &c. Many igneous rocks, however, are also arranged in layers or beds, as in the case of the basalt plateaus of Autrin, the Inner Hebrides, the Faeroe Islands, Iceland, &c. In these regions we encounter a great succession of sheets of basalt with interbedded layers of fragmental materials (tuff, &c.). Such consecutive series of igneous rocks are truly stratified. But when a geologist speaks of 'the stratified rocks' he is understood to refer more particularly to the derivative or aqueous rocks, the most important characteristic of which is their bedded or stratified arrangement. In a series of stratified rocks each individual layer of sandstone, shale, limestone, &c. is a stratum, which may or may not be homogeneous in structure. For while some beds consist of a series of thinner layers or laminae, others show no such subordinate divisions. Thus, the particular variety of sandstone which is called *freestone* is not laminated, but of homogeneous structure, while a stratum of shale is composed of numerous thin laminae. Such laminae have a more or less close cohesion, which is sometimes so great that it is almost as easy to break the rock against as with the grain. Individual strata are more readily separated from overlying and underlying beds. The degree of cohesion between laminae probably depends upon the rate at which sedimentation took place. If deposition was comparatively rapid the successive laminae would tend to cohere more readily than would be the case where each individual layer had had time to become more or less solidified before the deposition of the succeeding laminae. But in very many cases the cohesion of laminae has been effected by subsequent pressure, and sometimes by infiltration of cementing material. The planes of stratification are always more strongly pronounced than those of lamination, and generally point to some lapse of time (longer or shorter as the case

may be)—to a pause in the deposition of sedimentary matter. For further remarks, see GEOLOGY.

Straubing, an old town of Lower Bavaria, on the right bank of the Danube, 25 miles by rail SE. of Ratisbon, makes large quantities of bricks, lime, cement, and leather. Frannhofer was a native. In a little chapel here there is a monument to Agnes Bernauer (q.v.). Pop. (1925) 23,593.

Strauss, DAVID FRIEDRICH, was born on the 27th January 1808, at Ludwigsburg in Württemberg. His education was begun in his native town, and completed in the theological seminaries of Blaubeuren and Tübingen. In 1830, his head filled with Hegel's philosophy and Schleiermacher's theology, he became a country pastor; but already in the following year he was in Maulbronn acting as professor in the seminary. He was later *repentant* in Tübingen theological seminary, and lectured on philosophy in the university. All at once he became a man of mark by the publication, in 1835, of his *Life of Jesus critically treated* (4th ed. 1840; trans. by George Eliot, 1846). In this work he applied to the New Testament the method which had already worked havoc with the old legends of Greece and Rome, and which De Wette had to some extent applied to the Old Testament. Strauss attempted to prove the received gospel history to be a collection of myths gradually formed in the early Christian communities, and sought by an analytical dissection of each separate narrative to detect, where it existed, a nucleus of historical truth free from every trace of supernaturalism. The book made a real epoch in theological literature, and produced a violent excitement in and out of Germany, calling forth numberless replies from opponents, frightening many by its bold disregard of consequences back into the ranks of orthodoxy, and stirring up others to similar investigations. The first consequence to the author was his dismissal from his academical position in Tübingen, and transference to the Lyceum of Ludwigsburg. He soon retired into private life at Stuttgart, to have leisure to defend himself. In 1837 he published his *Streitschriften* against his opponents; and in 1838 *Zwei friedliche Blätter*, a more conciliatory exposition of his views. His appointment in 1839 to the Chair of Dogmatics and Church History in Zurich University raised such a storm of opposition that he had to be pensioned off, and the cantonal government fell.

Strauss's second great work was *Die christliche Glaubenslehre*, a review of Christian dogma 'in its historical development and its struggle with modern science' (1840-41). In *Der Kommtiker auf dem Throne der Cæsaren* (1847) a parallel was drawn between the orthodox William IV. of Prussia and Julian the Apostate, as having both attempted to restore dead religions. His fellow-townsmen put him forward as a candidate for the German revolutionary parliament of 1848, but he was unable to stand against the clerical influence; and when his native place sent him as its representative to the Württemberg Diet, he unexpectedly displayed conservative leanings, and soon retired. In this period he also issued lives of the Swabian poet Schubart and of his college-friend Christian Marklin; and a work on the old Swabian humanist Frischlin (1855). His third period of activity was opened in 1858 by a remarkable life of Ulrich von Hutten, followed up by the publication of Hutten's *Dialogues* in 1860, a work on Reimarus (1862), and a series of brilliant lectures on Voltaire (1870). A new *Life of Jesus, composed for the German People* (1864; trans. 1865), retaining the mythical theory, attempted—not very convincingly—to reconstruct a positive life of Christ. His last work, *Der alte und der neue Glaube* (1872),

endeavours to prove that Christianity as a system of religious belief is practically dead, that there is no conscious or personal God, and that a new faith must be built up out of art and the scientific knowledge of nature. Strauss died at Ludwigsburg, 8th February 1874. In 1841 he had married the opera-singer, Agnese Schiebest (1813-70), but some years after they separated. Strauss's literary, critical, and polemical powers were of a very high order; no more effective German prose than his had been written since Lessing.

A collected edition of Strauss's works was published in 12 vols. (including one of poems), edited by Zeller, in 1876-78. The *Life* by Zeller (1874) was translated the same year; and there are works by Hausrath (1878), Eck, Harraus, and Ziegler (1909). For his position in the history of criticism, see Schweitzer's *Quest of the Historic Jesus* (1910).

Strauss, JOHANN (14th October 1825-4th June 1899), composer, best known for his waltz-music, was born in Vienna, the son of a Johann Strauss (1804-49) who also was renowned as a composer of dance-music. On his father's death he took the direction of his orchestra, and for many years travelled with it, at the same time producing melodious and catching waltzes (*An der schönen blauen Donau*, *Künstlerleben*, &c.). He also composed some very popular operettas—*Die Fledermaus* (1874), *La Tsigane* (1877), *Der Zigeunerbaron* (1885), &c.

Strauss, RICHARD, was born on 11th June 1864, at Munich, where his father, Franz Strauss, was first horn-player in the Court Opera House. His aptitude for music showed itself very early. About the age of ten he became a pupil of Hofkapellmeister F. W. Meyer, and he soon acquired a scholarly knowledge of music. Many of his compositions received a public hearing while he was still gaining a wide general culture in the gymnasium and the university. He attracted the attention and came under the influence of Bilow, whom he succeeded in 1885 as Kapellmeister at Meiningen. After a visit to Italy he assisted Hermann Levi at the Munich Opera (1886-89) and Eduard Lassen at Weimar (1889-94). During a journey to Greece, Egypt, and Italy, undertaken to recover from the effects of overwork, he composed the opera *Güntram*. In 1894 he produced it at Weimar, and married the singer Pauline de Ahna, who performed the principal part. In the same year he became conductor at the Munich Opera House, and in 1898 at the Royal Opera House, Berlin. He was made Chevalier of the Legion of Honour in 1907. From 1919 to 1924 he was director of the State Opera House in Vienna. He has made many tours as a conductor, and excels in the interpretation of Mozart. As a composer his work falls into three periods: the first is occupied with sonatas, &c., in severely classical forms; the second, characterised by enormous orchestras and complicated scoring, comprises a set of brilliant tone-poems, *Don Juan* (1889), *Tod und Verklärung* (1890), *Till Eulenspiegel* (1895), *Also sprach Zarathustra* (1896), *Don Quixote* (1898), *Ein Heldenleben* (1899), and the operas *Salome* (1905) and *Elektra* (1909); in the third, an attempt is made at 18th-century simplicity with the operas *Der Rosenkavalier* (1911), *Ariadne auf Naxos* (1916), *Die Frau ohne Schatten* (1919), and the ballet *Schlagobers* (1923). Strauss has also written over a hundred songs, many of them very beautiful, but his astonishing contrapuntal virtuosity and command over the orchestra are often spoilt by a certain inconsistency of style. Frequently he strives after effect, but not only does he never lose touch of ordinary tonality, but he is apt to fall into the banal and common-place. His later works are, on the whole, inferior to those of his second period.

There are studies by Newman (1908), Specht (1920), and Muschler (1925). See PROGRAMME-MUSIC.

Stravinsky, IGOR, Russian composer, was born at St Petersburg in 1882, and in 1904 became a pupil of Rimsky-Korsakov. His works include the operas *Le Rossignol* (1909-14) and *Mavra* (1921), and the ballets *L'Oiseau de Feu* (1910), *Petrushka* (1911), *Le Sacre du Printemps* (1913), *Le Renard* (1915), and *Les Noces* (1923). His chamber music is comparatively insignificant. Stravinsky emphasizes the importance of rhythm, sacrificing melodic and harmonic development to it, and lays stress on the 'absolute' nature of music, freeing it from all emotional content. Though the three earlier ballets are magnificent examples of their kind (with brilliant and piquant orchestration) many of his subsequent works such as *L'Histoire du Soldat* (1917), and especially those in the smaller forms in which he makes use of rag-time rhythms, are, on the whole, neither convincing or permanent. His rhythmic audacities and excursions into atonality have aroused much discussion.

Straw, apart from its uses in agriculture, thatching, packing, for paper-making, and for mattresses and door-mats, is utilised to an enormous extent in the manufacture of hats and small baskets. Whent straw chiefly is employed in this plait trade, centred mainly in Bedfordshire in England, Tuscany in Italy, and Canton in China. At first the plait was what is called *whole straw*; that is, the straw was cut into suitable lengths without knots, and merely pressed flat during the operation of plaiting; and so it continued until the reign of George I., when it was in great demand for ladies' hats, and some plait was made of split straw. Since that time split straw has been chiefly used. The instrument employed for splitting consists of a number of little square steel blades radiating from a stem. The English straw used in plaiting is obtained principally from varieties of wheat which succeed best on the light rich soils of Bedfordshire and the neighbouring counties. Only bright, clear, and perfect pipes can be employed, and to obtain the straw in good condition great care has to be exercised. The crop is not mowed, but pulled up, and the ears are cut off by the hand for thrashing.

Strawberry. The Strawberry (Lat. *Fragaria*, whence the name of the genus *Fragaria*) belongs to the family Rosaceae. Probably our name is descriptive of the habit of the fruiting plant, when the berries are strewn or strawn upon the ground—*humus nascentia fraga*—by their weight on the flexible footstalk. It is hard to believe, on the best authority, that the plant waited for its name till straw was laid beneath it. The calyx is ten-cleft, the petals five, and the seeds are imbedded in a fleshy receptacle, which is the delicious and fragrant fruit. The plant is a dwarf perennial, of stocky habit, and with handsome foliage, each leaf consisting of three leaflets, boldly toothed, and deeply ribbed; the stalk is generally long, and more or less hirsute, according to variety. The principal species are *F. vesca*, including the alpine and wood varieties; *F. elatior*, the hantbois; *F. virginidis*, a rather scarce European plant; *F. virginiana*, a scarlet fruit; *F. grandiflora*, the pine strawberry; and *F. chilensis*, the Chilean. The hantbois, which is now believed to be a cultivated form of *F. vesca*, was probably our earliest garden strawberry, and the name is still used by the London street-vendors—'fine hoboy, ripe hoboy!'—for strawberries of all descriptions. The true hantbois is cultivated still for its rich and musky flavour, but larger and more fruitful kinds have generally superseded it. The magnificent fruit we now possess is chiefly the result of judicious crossings

betwixt and among *virginiana*, *grandiflora*, and *chilensis*. The first great improvement appears to have been the introduction of the scarlet kind from Virginia in the beginning of the 17th century; and the old scarlet, though too acid for dessert, is still the very best for preserving. *F. grandiflora*, the old pine, has larger fruit of higher flavour, and darker and more substantial leaves. It is believed to have come from Carolina, and under that name was regarded for some years as the best and finest of strawberries. Even now there is none to surpass it in flavour, or equal it perhaps in texture; but larger and more productive kinds have ousted it from popularity. The garden strawberries of the present time have been obtained by repeated crossings, and it is impossible now to give their pedigree; but many of them show by hispid stalk and foliage a trace of Chilean lineage, for the Chilean is a very hairy plant and of vigorous growth, but tender.

Planting strawberries for ourselves, we may rely upon a fine sweet crop if we show a little sense and take due care. First of all seek out the proper kinds for soil and climate, dividing (as may be fairly done, at least for practical purposes) all strawberries into three classes—(1) those of Chilean interbreed, which must have heavy soil even if poor, and weather not too barons; (2) those of more glabrous and substantial leaf, being closely allied to the pine race, which care more for the quality than the substance of the soil; (3) those of a strain so mixed that they must be studied individually, and sometimes flourish most upon a mixen. But however widely strawberries vary, almost all rejoice in having the earth well hardened around them, and the grower will marvel after all his labours to find the most vigorous and buxom of his plants established in the gravel-walk outside his higher culture. The strawberry is propagated in three manners—by seed, by side-shoots from the stool, and by runners. The last is the general course; and the runners or filiform stems (which issue generally at or soon after the fruiting season) should be pegged or fixed till the young plant is rooted. As early in the autumn as the young plants are strong enough, they are set out in the new beds in rows from 2 to 3 feet asunder, according to the vigour of the sort, and at intervals in the row of 15 or 18 inches. If the soil is light it should be rolled or heavily trodden before the planting time, and every young plant should have the earth rammed round it. Whenever a scarcity of runners or the weather has forbidden early planting it is better to wait till the spring than attempt to overtake the lateness lamely; and many kinds do best after wintering with their parents. The duration of a strawberry-bed depends very much upon the variety. Some of the small and early kinds are worn out by the second year of fruiting; while others of more robust habit do well for five or six years, or even more, if frequently cleared and kept in order and good heart. But none of these things has a hard and fast law. The forcing of strawberries is a special subject upon which we cannot enter. Brief as its season is of appearance in the market—from the first week of June to the last of July may be taken as the period of outdoor fruit in the neighbourhood of London—the strawberry has long won the affection of the people (at least for immediate despatch) more entirely than any or all other fruit whatsoever. At the height of the 'berry-time' it is amazing to see the fruit pouring into Covent Garden, from ship and from train, and by the English grower's van from all the nearer counties. The imported fruit is coarse, insipid, and generally in bad condition, but it serves to keep the prices low.

Strawberry Hill. See TWICKENHAM.

Strawboard is a kind of Millboard (q.v.), or thick cardboard, made of straw after it has been boiled with lime or soda to soften it. Cheap strawboards are used for making common boxes of various kinds, and for protecting articles sent by post or railway. Good qualities of board suitable for binding books and other purposes are made of straw mixed with flax and jute waste from spinning-mills.

Streatham, a suburban district of London, 6½ miles SSW. of St Paul's. The Thrales' house, visited by Dr Johnson, is gone; but the church, though rebuilt in 1831, retains some interesting monuments. Streatham is in the metropolitan borough of Wandsworth.

Streator, a mining-town of Illinois, on the Vermilion River, and on five railways, 94 miles SW. of Chicago. Pop. 15,000.

Street, GEORGE EDMUND, architect, born at Woodford in Essex, 20th June 1824, was educated at Camberwell and Crediton, and studied for five years with Gilbert Scott. Starting in practice for himself in 1849, he designed many churches and restored more—the chief restoration being Christ Church Cathedral in Dublin. Cuddesden College and Uppingham School are by him; but his most famous work is the Law Courts in London, the subject of so much controversy (see Vol. VI. p. 739). Street became an A.R.A. in 1866, an R.A. in 1871, and P.R.I.B.A. in 1881. He died in London, 18th December 1881, and was buried in Westminster Abbey. He published *The Architecture of North Italy in the Middle Ages* (1855) and *Gothic Architecture in Spain* (1865). See Memoir by his son (1888), and G. G. King, *Unpublished Notes and Reprinted Papers* (1917).

Strength of Materials is the heading under which it is usual to discuss the elastic or resisting properties of the materials used in engineering or building operations (see ELASTICITY, also STRAIN AND STRESS). When a structure is being designed the engineer must know first of all the amount and character of the stresses (loads, wind-pressures, &c.) that will act upon the structure. He must then decide as to the size and shape of the pieces that are to compose the structure, so that they may easily stand these stresses. For this purpose he must know beforehand what 'strength of material' is possessed by the steel, iron, or wood that is to be used.

When any substance is strained beyond a certain limit it will break, and the greatest stress which the substance can bear without being torn asunder is called its ultimate strength. The value of this for any given piece of material will depend upon the kind of strain to which it is being subjected. But whatever this strain be, whether extension, compression, flexure, or twisting, there are two, or at most three, distinct kinds of ultimate strength which practically fall to be considered. The one is the ultimate tension or pressure applied in one direction, usually longitudinally; and the other is the ultimate shearing stress, such as comes into play in simple torsion. In certain cases, such as in steel, wrought-iron, and ductile metals generally, the strength under tension and that under longitudinal pressure—in other words, the tenacity and the resistance to crushing—are practically the same. In other cases, however, of which cast-iron is the most interesting instance, the resistance to crushing is much greater than the tenacity. The ultimate strength under shearing is generally less than that under tension or compression. For example, the ultimate tensile strength of steel varies from 30 to 45 tons' weight per square inch of section, while the ultimate shearing strength

varies from 22 to 35. Cast-iron, again, which has a tensile strength of $7\frac{1}{2}$ tons' weight per square inch, has a strength under crushing of 45 and a shearing strength of 12. The requirements of designers of the motor-car and aeroplane have led to considerable improvements in the materials used in their construction, so that there are now available high-carbon and alloy-steels containing chromium, tungsten, or vanadium which have peculiar qualities of resistance to tensile stress or shock, or, after special heat treatment at very definite temperatures, acquire a high degree of hardness, toughness, or elasticity as may be required for the particular service for which they are intended. In this connection steels having a tensile strength of 70 tons per square inch of section are in regular use.

It is out of the question to make a structure in which the pieces are strained up to their ultimate limits. For, even although the limit is not exceeded and the material not torn asunder, the excessive straining to near the limit will produce a permanent deterioration in strength. In other words, the 'working strength' is much smaller than the ultimate strength, being obtained from it by dividing by a number known as the 'factor of safety.' In the case of steel this factor is about 6; so that in no structure should a hard steel rod be subjected to a greater tension than $7\frac{1}{2}$ tons' weight per square inch. Experience is the sole guide as to the value of this factor which must be taken large enough to provide a margin of strength for all possible contingencies. Again, although theoretically a long column should have the same tensile strength as a short one of the same material and section, practically it is not so. There is greater chance of there being weak places in the longer column, and at the weakest place the material will begin to yield. Thus a greater factor of safety must be used in estimating the working strength of the longer rod. Manufacturers are, however, now prepared to supply materials such as iron and steel of quite regular quality, which will satisfy a very exact chemical specification and mechanical tests, a small percentage of the tonnage supplied is tested to destruction to check the quality. Then, in the second place, the character of the stress to which the material is to be subjected must be considered. If it is to be a fluctuating and not a steady stress the factor of safety must be increased, and similarly a wider margin of strength must be provided if the material is to be subjected to sudden shocks or impacts. For example, a bridge which is strong enough to allow a train to rest on it or to crawl over it may be unable to support the train dashing at full speed. In fact, under a stress which fluctuates between wide limits the ultimate strength is diminished, and this has given rise to the design of machines for the testing of samples of material under varying and reversing loads and under shock.

A very important part of the subject is the consideration of the form best suited to resist certain strains. A glance at any fine modern structure, such as the Forth Bridge, will show how the form is varied, according as the member is in compression or in extension. Here the question of bending action enters in. For although the strengths under extension and compression may be the same, yet if a rod is taken too thin and subjected to a longitudinal pressure, it will bend long before the true compression limits are reached. This bending or buckling must be prevented, and the only way of doing so is to increase the lateral dimensions of the section. Thus tubular or hollow figures resist buckling better than rods of the same length and mass. Herein also lies the great virtue of the I-shaped rod, which if laid horizontally and sup-

ported by its ends bends under its own weight very slightly as compared with the bending of a solid cylindrical rod of the same length and mass.

See Sir J. A. Ewing, *Strength of Materials* (1914); Prof. J. Goodman, *Mechanics Applied to Engineering* (1919); E. S. Andrews, *Strength of Materials* (1925); Dr. A. Morley, *Strength of Materials* (1923, reprint 1925); Dr. A. Morley, *Theory of Structures* (1912, reprint 1923); J. Husband and W. Harly, *Structural Engineering* (1924); J. Case, *Strength of Materials* (1925).

Strepsiptera, very peculiar insects, sometimes referred to Coleoptera, sometimes to an order by themselves. They are parasitic inside other insects, of the orders Hymenoptera and Hemiptera. Bees modified by them are said to be 'stylopedis,' Stylops being the name of a common Strepsipteron. The young larvæ, called triungulins, enter the larva of the host—e.g. the grub of the bee *Andrena*; they feed and develop; the males emerge as minute, very active, short-lived, winged insects; the females remain as degenerate stationary sacs, developing triungulins in their interior.

Streptococcus. See BACTERIA.

Stress. See STRAIN.

Stretton. HESBA, the pen-name of Sarah Smith, novelist and popular writer for the young, who was born at Church Stretton, Shropshire, the daughter of a bookseller. Her first manuscript was accepted by Charles Dickens, and published in *Household Words* (1859), to which she continued to contribute, as also to *All the Year Round*, until the death of its founder, whom she had found the most generous and sympathetic of editors. *Jessie's First Prayer*, published by the London Tract Society in 1867, was followed by a long series of semi-religious stories. She died, 8th October 1911.

Streuvels, STIJN, Flemish novelist, whose real name is Frank Latem, was born in 1871 the son of a baker. He himself plied the trade of pastry-cook at Avelghem before settling down to literature. As the author of vivid and artistic stories of peasant life he enjoys a wide popularity in Holland and to some extent in Germany. His chief works are *De Aanslag*, *De Oogst*, *De Werkman*, *Levens de Wegen*, *Mijn Wijfje*, *Open Lucht*, *Stille Aranden*, and *Zomerland*.

Strickland, AGNES, historian, was born at Reydon Hall near Southwold, Suffolk, August 19, 1806. She had begun verse-making ere her twelfth year, and had issued several volumes of poetry when the idea occurred to her of writing historical biographies of the queens of England. The suggestion came from some interesting biographies of female sovereigns written for a periodical by her sister Elizabeth (1794-1875). A start was made, and the first two volumes were published by Colburn and had a rapid sale; a misunderstanding between author and publisher was healed by Colburn's offer of £150 per volume until the work was completed (12 vols. 1840-48; new ed. 6 vols. 1864-65; abridged ed. 1867). In the production of this work she was assisted by her sister Elizabeth, though only the name of Agnes appears on the title-page. The work was dedicated to Queen Victoria, and as each volume appeared its picturesque style and anecdotal character made it a general favourite, though the *Quarterly Review* complained of a poverty of style and an equally pervading feebleness of thought, while the *Times* said it possessed 'the fascination of a romance united to the integrity of a history.' Miss Strickland, whose volumes give vivid pictures of the court and domestic life of the various periods, had strong opinions as to ecclesiastical government and royal prerogative, and was a partisan of the Stuarts. A civil list pension was conferred upon her in 1870. She died 8th July 1874. Agnes

Strickland also wrote several novels and juvenile tales. Other works, written jointly with her sister Elizabeth, were *Lives of the Queens of Scotland (1850-59)*, *Lives of the Seven Bishops (1866)*, *Lives of the Tudor Princesses (1868)*. The remaining works from the pen of Agnes were *Victoria from Birth to Bridal (1840)*; *Letters of Mary Queen of Scots*, in whose innocence she believed (1842-43; new ed. 1861); *Bachelor Kings of England (1861)*; *Lives of the Last Four Stuart Princesses (1872)*. Her *Life of Mary Queen of Scots* (2 vols. 1873) was a redaction from the volumes in the *Queens of Scotland*. See *Life*, by her sister Jane (1887).

Stricture is a term employed in Surgery to denote an unnatural contraction, either congenital or acquired, of a mucous canal, such as the urethra, œsophagus, or intestine. When, however, the affected part is not mentioned, and a person is stated to suffer from stricture, it is always the urethral canal that is referred to. Contraction of this canal may be either permanent or transitory. The former is due to a thickening of the walls of the urethra in consequence of organic deposit, and is hence termed organic stricture. The latter may be due either to local inflammation or congestion, or to abnormal muscular action; the first of these varieties may be termed inflammatory or congestive stricture, and the second spasmodic stricture. The last-named form seldom exists except as a complication of the other kinds of stricture. There are two principal causes of organic stricture—the first being inflammation of the canal, and the second injury by violence. Inflammation is by far the most common cause, and gonorrhœa is the common agent by which it is excited. Not unfrequently stimulating injections thrown into the urethra with the view of checking the gonorrhœal discharge excite an inflammatory action which gives rise to stricture. Fortunately it is only in exceptional cases that a stricture results from inflammation of the urethra, the inflammation, in the great majority of cases, terminating by resolution, and leaving the canal as healthy as before the attack. It is when the complaint assumes a chronic character that it most commonly lays the foundation of stricture. Stricture from injuries is produced by such causes as falling across spurs, scaffolding, ladders, &c., or from some sharp object which punctures the perineum—e.g. earthenware vessels which break under the sitter.

The earlier symptoms of stricture are a slight urethral discharge and pain in the canal behind the seat of the stricture at the time of micturition. The stream of urine does not pass in its ordinary form, but is flattened or twisted; and as the disease advances it becomes smaller, and ultimately the fluid may only be discharged in drops. The straining efforts to discharge the urine often induce Tenesmus (q.v.).

As the case advances the urine becomes alkaline and ropy, and deposits a precipitate when allowed to stand; and attacks of complete retention of urine occur with increasing frequency. But these symptoms are not in themselves sufficient to establish the presence of stricture. It is necessary to examine the urethral canal with a Catheter (q.v.) or Bougie (q.v.) to ascertain whether an organic obstruction exists, whether one or more strictures are present (as many as eight have been recorded, although four are rare, and one is the most common number), and their calibre. The treatment of organic stricture is too purely surgical to be discussed in these pages. It is sufficient to state that its object is twofold—viz. first, to restore the natural calibre of the canal so far as this can be safely effected; and secondly, to maintain this patency after it has been established.

Spasmodic stricture usually occurs as a complication of organic stricture or of inflammation of the mucous membrane, but may arise from an acrid condition of the urine, from the administration of cantharides, turpentine, &c., and from the voluntary retention of urine for too long a time. The treatment consists in the removal of the causes as far as possible and the hot bath. The inhalation of chloroform sometimes gives immediate relief; and several cases are recorded in which when the spasm occurred periodically it was cured by quinine. Inflammatory or congestive stricture commonly arises from some local irritation such as exposure to cold, gravel, from indigence in alcohol, &c. The patient complains of heat, fullness, and soreness in the perineum; the passage of the urine is extremely painful, the stream being small and ceasing before the bladder empties. The treatment is much the same as that for retention of Urine (q.v.).

Striegau, a town of Lower Silesia, 25 miles SE. of Liegnitz, with granite-quarries, and manufacture of brushes, whips, sugar, &c. At Hohenfriedberg near by Frederick defeated the Austrians in 1745. Pop. 14,000.

Strike, a term borrowed by geologists from the German *streichen*, 'to extend,' and adopted with the technical meaning it has in that language. It is applied to the direction of a stratum. This line always at right angles to the dip of the bed. The angle of dip and the direction of strike are determined by a clinometer and compass. A perfectly horizontal stratum can have neither dip nor strike.

Strikes. See COMBINATION, TRADE UNIONS.

Strindberg, JOHAN AUGUST, the most prominent figure in modern Swedish literature, was born in unhappy circumstances at Stockholm on 22d January 1849. His keenly sensitive nature, subjected to a family life of poverty and even squalor, prompted the early growth of that restless cynicism and discontent which characterises so much of his work. He entered Upsala university in 1867, but his studies were intermittent. He later became successively schoolmaster, journalist, telegraph employee, tutor, and librarian at the Royal Library, where he learned Chinese. But he had turned to writing other than journalism. His first great drama, *Master Olof*, was written in 1872, but not thought worthy of publication till 1878. Strindberg's mortification at the delay called forth his *Red Room* (1879), a bitter satire upon conventional Swedish society. This made its author enemies, and to their attacks he replied in another stinging satire, *The New Kingdom* (1882); but after its publication he had to go into voluntary banishment. Two years later he published a collection of short stories, *Married*, in which he protests against the prevalent idealisation of woman, and describes all sorts and conditions of nuptial alliances with cynical frankness. Accused of outraging Christianity in this book, Strindberg repaired to Stockholm and stood his trial. After making an eloquent defence he was acquitted, and two years later he produced a second collection of stories under the same title, but much more vehement in their denunciation of women than the first. The same general theme, carried to morbid excess, inspires his autobiographical *Fool's Confession* (1888). Four autobiographical novels, *The Bondswoman's Son*, *Fermentation Time*, *In the Red Room*, *The Author*, appeared in 1886-87, and were followed by three more novels describing with admirable art the life and manners of the inhabitants of the Stockholm skerries—*The People of Hemsö*, *Fisherfolk*, and *At the Edge of the Sea*, the last, written under Nietzschean influences, showing Strindberg the novelist in his most genuine mood. By 1880 Strindberg had already written

some half-dozen plays. Three more followed in 1880-83—*The Secret of the Guild*, *Sir Bengt's Wife*, *The Journey of Lucky Peter*. The series of thirteen plays (1887-97), beginning with the powerful play *The Father*, and including *Lady Julie*, *Comrades*, *Creditors*, *The Link*, gained Strindberg a European reputation as an exponent of the naturalistic drama and as an unconventional misogynist. But while Berlin and Paris were acclaiming his genius as a playwright, he gave up writing and turned to a study of the exact sciences to quiet his tormented soul. He hoped to revolutionise chemistry, he dabbled in alchemy, he became a visionary, and gradually went mad. When he regained his mental balance he mirrored the 'great crisis' in his auto-biographical *Inferno* (1897) and *Legends* (1898), unique works of their kind. More at rest now, enjoying 'light after darkness,' he returned for a few years (1898-1903) completely to the field of drama, and showed his absolute supremacy there both in the subtle psychological characterisation of the historical plays (*The Saga of the Folkungs*, *Gustavus Vasa*, *Eric XIV.*, *Engelbrecht*, *Charles XII.*, &c.), and in the mystic, imaginative flights of *To Damascus*, *Advent*, *Easter*, *Swan-white*, *The Dream Play*, &c. Ten more plays appeared in 1907-9, making a total of fifty-three during his lifetime. There are also voluminous historical writings, essays, treatises on the theatre and philology, stories, and poems, for Strindberg was a veritable titan of literature. He was no orator. His literary style is rich, generally pure, voluble; his moods are many—lyrical, artistic, vigorous, cynical, turbulent. His character is one of contrasts and inconsistencies, yet his philosophy—an adent subjectivism—is clear enough. Until his later years he was without honour in his own country, and to the end he made no peace with the Swedish Academy. But his sixty-third birthday was an occasion of national celebration, and his death on 14th May 1912 one of national mourning. Bjorkman translated (1912) three of his plays, with a valuable introduction, and several other volumes translated by him and by E. and W. Oland followed. Many of Strindberg's other works have been translated also. See, besides Strindberg's autobiographical works noted in the article, an English study by Miss Lind-af-Hageby (1913), and A. Henderson's *European Dramatists*.

Stringhalt is a peculiar catching up of the horse's limbs, usually of one or both hind-legs. It is most noticeable when the animal is first brought out of the stable, when he is excited, or made to turn suddenly round. A variety of chorea or St Vitus's dance, it may not interfere with usefulness, but is a serious eyesore, as a rule incurable, and depreciates the value of the horse.

Strode, RALPH, a schoolman who flourished between 1350 and 1400, was apparently born in the west of England, studied at Oxford, and, as a fellow of Merton, opposed his colleague Wycliffe. To him and Gower Chaucer dedicated *Troilus and Criseide*. He was eminent as a logician and philosopher, but only fragments of his work survive or have been printed. For a while he had a European reputation.

Strode, WILLIAM (c. 1600-45), born probably near Plympton, Devon, from Westminster passed to Christ Church, Oxford, and became chaplain to the bishop (Richard Corbet the poet), canon, and public orator, as well as doctor of divinity. He had some repute in his own time as a lyric and elegiac poet, but was almost totally forgotten when his poems were first edited by Bertram Dobell in 1907.

Stromboli, one of the Lipari Islands (q.v.), with a volcano almost constantly active.

Strombus, a genus of marine Gasteropods, typical of the family Strombidae. Their shells, often called conch-shells, are well known, being often used as decorative objects and in the manufacture of cameos (see *CAMEO*). Large numbers are exported from the West Indies and other tropical regions, and it is recorded that 300,000 fountain-shells (*Strombus gigas*) were brought to Liverpool in 1850. This species is the largest Gasteropod, the shell sometimes weighing 4 or 5 lb. The stromb-shell has a short conical spire and a much expanded outer lip, to which the popular name 'wing-shell' refers. The animals are allied to the cowries and whelks (*Buccinum*),

Fountain-shell (*Strombus gigas*).

and are very active, moving by short jumps. They feed on dead and decaying animal matter. See *CONCH*.

Stromness, a seaport in Mainland, Orkney, on a beautiful bay, 15 miles W. by S. of Kirkwall. Tow, Scott's 'Pirate,' was born here. Pop. 1660.

Strongbow. See *PEMBROKE*.

Stronsay, one of the Orkney Islands (q.v.).

Strontium (sym. Sr.; dyad, atom. wt. 87.3, atom. number 38; sp. gr. 2.542) is a ductile pale yellow metal, prepared by the electrolysis of the fused chloride. It occurs as the carbonate in the mineral *Strontianite* (so called from being first found in 1790 at *Strontian* in Argyllshire) and as the sulphate in *Celestine*. It belongs to the barium group of metals, and has most of the properties of the group. Its salts, especially the nitrate and chlorate, are used in pyrotechny for the purpose of producing a crimson flame. The metal decomposes water at the ordinary temperature, evolving hydrogen, but it is hardly affected in pure dry air. Its oxide and hydroxide are used in the purification of beet-sugar as its compounds are non-poisonous. The soluble salts are the nitrate $\text{Sr}(\text{NO}_3)_2$, the chloride, SrCl_2 , and the chlorate $\text{Sr}(\text{ClO}_3)_2$. Strontium is detected by giving a precipitate with sulphuric acid or with soluble sulphates, and by imparting a crimson colour to the Bunsen flame; it is distinguished from barium by the fact that it is not precipitated by silico-fluoric acid or by thiosulphates. The pure metal was first prepared by Bunsen in 1855, but Davy had separated it in an impure condition in 1807.

Strophanthus, a genus of Apocynaceae, natives of tropical Africa and Asia. The flowers are in terminal heads; the corolla is funnel-shaped, with its limbs divided into five long cord-like segments (hence the name, Gr. *strophos*, 'a twisted cord,' *anthos*, 'a flower'); the style is thread-like, surmounted by a cylindrical stigma; and the fruit is a double follicle. Each follicle contains a large number of seeds having beautiful comose awns. There are several species, but the best known is *Strophanthus Kombé*, the seeds of which are largely used in medicine. This species is widely distributed in tropical Africa, and climbs up

the highest trees, hanging from one to the other in festoons. It has foliicles 8 to 12 inches long, containing from about 100 to 200 seeds, each of which weighs about 3 centigrams. An extract of the seeds is used as an arrow-poison (Kombé or inee) in districts widely apart, as at Kombé, in the Manganja country, in the Zambezi district, in the Somali country, in the Gabun district, in Guinea, and in Senegambia. Dr Livingstone described it as used for killing animals only. The wounded animal is followed until the poison begins to take effect, it is then watched until it drops, the portion of meat round the wound is cut away, and all the rest eaten.

In the British Pharmacopœia *Strophanthus* is defined as the mature ripe seeds of *Strophanthus Kombé*, freed from the awns. Each seed is about $\frac{1}{2}$ inch long, $\frac{1}{4}$ inch broad, oval in shape, and flattened at the sides. The seed-coat is of a fawn colour, and covered with silky hairs. The kernel is white and oily, with a very bitter taste. The seeds contain an active principle, *strophanthin*, which is extremely poisonous, the medicinal dose of it being $\frac{1}{16}$ to $\frac{1}{8}$ grain. The drug is usually administered in the form of the official tincture of *strophanthin* made from the seed, of which the dose is 12 to 30 centimils (2 to 5 minims). Its action and uses are very similar to those of *Digitalis* (q.v.).

Stroud, a manufacturing and market town of Gloucestershire, 9 miles SSE. of Gloucester, on an eminence in a valley sheltered by the Cotswolds, where the Frome and Slade rivulets unite to form the Stroud Water or Frome. The water of this stream being peculiarly adapted for use in dyeing scarlet and other gaudy colours, cloth-factories and dyeworks have been built along its banks; and Stroud itself is the centre of the woollen manufactures of Gloucestershire, and contains a number of cloth-mills. The parish church, St Lawrence, was rebuilt, with exception of the old steeple, in 1867; the town-hall, incorporating an Elizabethan façade, in 1865, and there are also the Subscription-rooms (1836), the Holloway Institute, and art and technical schools. Stroud makes an excellent centre for visiting the Cotswold district. From 1832 to 1885 it formed a parliamentary borough with twelve other parishes, returning two members. Pop. (1881) 9535; (1921) 8561.

Struensee, JOHANN FRIEDRICH, COUNT, was the son of a German pastor of Halle, where he was born 5th August 1737. He studied medicine, and was appointed (1759) town physician in Altona. But in 1768 he accepted the post of private physician to Christian VII. of Denmark (1749-1808). He soon gained the complete confidence not only of the weak young king, but also of his consort, Caroline (1751-75), sister of George III. of England, who had a most unhappy lot as the wife of Christian. Struensee and the queen speedily possessed themselves of all power in the kingdom, dismissing the former ministers, forcing the king to abstain from all interference with government, and endeavouring to free Denmark from Russian influence, and to find a natural ally in Sweden. The changes which Struensee undertook in internal affairs were directed to the advancement of the prosperity of the country, of civil liberty, and enlightenment. He put the finances in order, reduced the expenditure, loosened the fetters in which industry and trade had been bound, encouraged education, mitigated the penal laws, and brought order into the administration. An act passed in 1771 to a certain extent abolished serfdom. But by all these measures he offended and outraged the nobility and the clergy, and by the haste and want of statesmanlike tact and skill with which they were carried out he appeared to the peasantry as little different from a despotic tyrant.

The disaffected nobles and deposed ministers found a supporter in Christian's step-mother, and procured from the king an order for the arrest (16th January 1772) of the queen and Struensee. From both a confession of criminal intimacy was extorted; the queen was confined in the prison-fortress of Kronborg, while Struensee was cast in chains into the citadel of Copenhagen. Various charges of abusing the royal authority, attempting to force the king to abdicate, besides that of adultery with the queen, were laid to the charge of the favourite, and on 28th April 1772 he was beheaded. Queen Caroline's marriage was dissolved, and, parted from her only little daughter, she was conveyed by a British frigate to Hanover, where she died at Celle in 1775.

See a very full account in the *Memoirs and Correspondence* (1849) of Sir Robert Murray Keith, who was British envoy to Copenhagen at the time, and saved the queen from the fury of the populace; Waxall's *Life and Times of Queen Caroline Matilda* (3 vols. 1864); the article by Ward in *Dict. Nat. Biog.* (vol. ix.); and late by Wilkins, *A Queen of Tears* (1904).

Strutt, JOHN WILLIAM. See RAYLEIGH.

Strutt, JOSEPH, antiquary, was born at Springfield in Essex, 27th October 1742, at fourteen was apprenticed to an engraver, studied art in the Royal Academy, and early gave himself to exceptionally laborious studies at the British Museum. He died in London 16th October 1802, after a life spent, spite of poverty and sickness, in devotion to learning. His most important book was his last, the invaluable *Sports and Pastimes of the People of England* (1801; enlarged by Cox, 1903). Other books were his *Regal and Ecclesiastical Antiquities of England* (1773); *Harda-Angel-Cynnan*, or a complete view of the Manners, Customs, Arms, Habits, &c. of the Inhabitants of England (1774-75-76); *Chronicle of England*, down to the Norman Conquest (1777-78); a *Biographical Dictionary of Engravers* (1785-86); and *Complete View of the Dress and Habits of the People of England* (1796-99). See Life by Miller-Christy (1898).

Struve, FRIEDRICH GEORG WILHELM, German astronomer, was born at Altona, April 15, 1793, educated at the university of Dorpat (Russia), and appointed to a post in the observatory of that place in 1813. He became director of the Dorpat Observatory in 1817, and in 1839 was placed at the head of the new observatory of Pulkova near St Petersburg. He retired in 1861, and died at St Petersburg on 23d November 1864. He directed his attention principally to the observation of double stars, and collected materials for three important works (1827, 1837, 1852) dealing with this branch of astronomy. He also carried out a number of important geodetic operations, such as the triangulation of Livonia (in 1816-19) and the measurement of an arc of the meridian in the Baltic Provinces (in 1822-27), which was subsequently (1828-56) extended by him, in conjunction with Hansteen (q.v.) and Selander, to the North Cape, and by General Tenner southwards to Ismail in Turkey. For this last gigantic undertaking, see *Struve's Arc du Méridien entre le Danube et la Mer Glaciale* (St Petersburg, 1857-60). --His son, OTTO WILHELM STRUVE (in Russia Vassilievitch, as his father was Vassili), also an astronomer, was born at Dorpat, May 7, 1819, became his father's chief assistant and successor at Pulkova. He made many astronomical discoveries, including 500 new double stars and a satellite of Uranus, and published papers on the rings of Saturn, the periodic motions of double stars, &c. He died 14th April 1905. --One of Otto's sons became director of the observatory at Berlin, and another professor of Astronomy at Kharkoff.

Stry, or **STRYI**, a town of Eastern Galicia, on a tributary of the Dniester, 45 miles by rail S. of Lemberg, with sawmills and tanneries. Pop. 30,000, nearly one-half Jews. The town was almost wholly burned down in April 1886.

Strychnine, a poisonous drug, is named from the genus *Strychnos* (q.v.). The most notable species is *S. Nux-vomica*, so called from the name *Nux Vomica* given to its seeds, the source of strychnine. The tree and its seeds are described at *NUX VOMICA*. From various species of *Strychnos* are obtained the Clearing nut (q.v.), the Curari (q.v.) poison, and Ignatius Beans (q.v.); while one kind of *Upas* poison (*Upas teute*) is made from a species of *Strychnos*.

Strychnine, $C_{21}H_{22}N_2O_8$, is an alkaloid occurring in crystals, has an intensely bitter taste, is colorless and inodorous, scarcely soluble in water, but easily soluble in boiling rectified spirit, in ether, and in chloroform. Pure sulphuric acid forms with it a colorless solution, which, on the addition of bichromate of potash, acquires an intensely violet hue, speedily passing through red to yellow. In nitric acid it ought, if pure, to form a colorless solution; if the solution is reddish it is a sign that brucine is also present. Strychnine combines with numerous acids, and forms well-marked salts, which give the same reactions as the base itself. *Nux vomica* seeds contain about 2 to 5 per cent. of it. *Brucine* (q.v.) is also present.

Strychnine and brucine occur not only in *nux vomica*, but in the seeds of *Strychnos Ignatii* (St Ignatius' beans) and in the seeds and other parts of several plants of the genus *Strychnos*. *Nux vomica* and its alkaloids are very poisonous to all kinds of animals. It is believed, however, that the bird called *Buceros rhinoceros* eats the nuts with impunity; and a peculiar kind of *Aearns* lives and thrives in the extract of the nuts. In small doses ($\frac{1}{32}$ th to $\frac{1}{16}$ th grain) it is largely used in medicine as a stimulant, as a tonic, and as a bitter. The official preparations are made from *nux vomica* and from strychnine. In poisoning with strychnine the symptoms depend on excessive stimulation of the spinal cord, and when fully developed consist in rigid tetanic convulsions. These are preceded by muscular twitchings, cramps, and jerking movements. Each spasm lasts one or two minutes, and is followed by a short remission, during which the person lies completely exhausted, but able to converse and swallow. The slightest touch, a noise, or even a draught of air will bring on a spasm. The mind generally remains quite clear. Death takes place within two hours from exhaustion, or from suffocation produced by the impossibility of breathing during the spasms. Death may occur in a few minutes, however; a quarter of a grain is the smallest fatal dose of strychnine recorded, but patients have survived much larger amounts.

The treatment, after emptying the stomach, consists in keeping the patient as quiet as possible, and in administering substances which will depress the spinal cord, and thereby allay the tetanic spasms. Chloral hydrate and bromide of potassium by the mouth or rectum have been found useful in this respect. But putting the patient deeply under the influence of chloroform is probably the most efficacious mode of treatment.

Strychnos, a tropical genus of trees and climbing shrubs, of the Loganiaceæ, several species of which produce edible fruits. Both the Dayaks of Borneo and the Indians of Guiana and Brazil get the poisons for their blowpipe-darts from this genus. See also *BRUCINE*, *CLEARING-NUT*, *CURARI*, *IGNATIUS BEANS*, *NUX-VOMICA*, *STRYCHNINE*.

Strype, JOHN, a voluminous ecclesiastical historian, was born in London, November 1, 1643,

the same year as Burnet. He was educated at St Paul's School, whence he passed first to Jesus College, then to Catharine Hall, Cambridge. He was presented in 1669 to the perpetual curacy of Theydon-Bois in Essex, which he resigned a little later to become minister of Low Leyton in the same county. Later he received the sinecure of Tarring in Sussex and the lectureship of Hackney, which he resigned in 1724. He died at Hackney, December 11, 1737, aged ninety-four. His works fill thirteen folio volumes (27 vols., Clar. Press ed., 1821-43). The most important are *Memorials of Archbishop Cranmer* (1694); *Life of Sir Thomas Smith, Secretary of State to Edward VI. and Elizabeth* (1698); *Lives of Bishop Aylmer* (1701), *Sir John Cheke* (1705), *Archbishop Grindal* (1710), *Archbishop Parker* (1711), and *Archbishop Whitgift* (1718); *Annals of the Reformation* (vol. i. 709, vol. ii. 1723, vol. iii. 1728, and vol. iv. 1731); *Ecclesiastical Memorials*, relating to religion and the Church of England under Henry VIII., Edward VI., and Queen Mary (3 vols. 1721). This last is his best work, forming, with Burnet's more readable *History of the Reformation*, a consecutive and full account of the reformed Anglican Church. Strype also published an enlarged edition of Stow's *Survey of London* (2 vols. 1720), with several sermons and pamphlets. As a writer he is heavy and unskilful in arrangement, but laborious and honest, and his transcriptions of the ancient papers he published may be trusted. A simple-minded but sincere man, he has left to posterity a series of works of the very greatest value despite their prolixity, irrelevant details, and tiresome repetitions.

Stsherbatsky, FEDOR IPPOLITOVICH, Russian scholar, born in 1867 at St Petersburg, studied philology, and in 1904 became professor of Indian literature at St Petersburg University. A profound student of Buddhism, he has made several authoritative contributions to learning, notably *The Theory of Knowledge and Logic according to the Later Buddhists* (1899), *The Central Conception of Buddhism* (1923), *The Conception of Nirvana* (1926).

Stuart. See STEWART.

Stuart, GILBERT CHARLES, American painter, was born at Narragansett, R.I., 3d December 1755. In his boyhood he went to Edinburgh with a Scots painter named Alexander, with whom he studied his art; but his master dying, he worked his passage home, and began to paint portraits at Newport. In 1775 he made his way to London, where he led for two years a Bohemian life; but his talent was recognised by his countryman, Benjamin West, who took him into his family, and soon he became a fashionable portrait-painter. In 1792, in the fullness of his powers and fame, he returned to America, and painted portraits of Washington, Jefferson, Madison, John Adams, and many of the distinguished men of the period, and was at work on a portrait of John Quincy Adams (afterwards finished by Sully) when he died at Boston, 27th July 1828. See a *Life* by G. C. Mason (New York, 1879).

Stuart, JOHN, LL.D. (1813-77), a Scottish antiquary, for twenty-four years attached to the Register House. His principal works were *The Sculptured Stones of Scotland* (2 vols. 1856-67) and *The Book of Deer* (see *DEER*). He contributed largely to the *Proceedings* of the Scottish Society of Antiquaries, of which he was secretary.

Stuart, MOSES, American divine and author, was born at Wilton, Connecticut, in 1780, and educated at Yale, where he remained for some time as a tutor. He began the study of law, but

abandoned it for theology, was ordained as pastor of a Congregational church at New Haven in 1806, and in 1810 was appointed professor of Sacred Literature at Andover, a position he filled till 1848. During this period he published Hebrew grammars without (1813) and with points (1821), a translation of Winer's Greek grammar, commentaries on Hebrews, Romans, the Apocalypse, Daniel, Ecclesiastes, and Proverbs; *Hebrew Chrestomathy* (1829-30); *Essays on Future Punishment* (1830) and on *Christian Baptism* (1833); *Hints on the Interpretation of Prophecy* (1842); *Conscience and the Constitution* (1850); and numerous translations and letters. He died January 4, 1852.

Stubbbs, JOHN, was born about 1541, had his education at Corpus Christi College, Cambridge, and Lincoln's Inn, and died about 1600. He wrote an answer to Cardinal Allen's *Defence of the English Catholics*, but is known by *The Discoverie of a Gaping Gulf, wherein England is like to be swallowed up by another French Marriage* (1579), against the marriage of Elizabeth with the Duke of Anjou. For his patriotism both himself and Page his printer had their right hands struck off.

PHILIP STUBBES, his near kinsman, was author of the *Anatomic of Abuses* (1583): contemning a Discoverie or Briefe Summarie of such Notable Vices and Imperfections as now raigne in many Christian countreies of the World: but especially in a very famous Ilande called Ailgma: Together with most fearful Examples of Gods Judgements executed upon the wicked for the same as well in Ailgma of late, as in other places elsewhere. Wood tells us that he was 'a most rigid Calvinist, a bitter enemy to popery, and a great corrector of the vices and abuses of his time; and though not in sacred orders, yet the books he wrote related to divinity and morality.' A second part of his book appeared the same year (1583). In form it is a dialogue between Philoponus and Spudens; the substance is a vehement denunciation of the luxury of the times, valuable in the highest degree to us for the light it throws on the dress and habits of the age of Shakespeare. Stubbbs is, himself, really a bigoted and splenetic old fool, and he inveighs with curious passion against all extravagances of dress 'the great ruffs, pulled out doublets of the men; the curling, frizzling, and crisping of the hair of the women; their great ruffs and neckerchers of holland, lawne, camerieck, and such coller, lest they should fall down, smeared and smeirched in the devil's liquor—sturch.' In his blindness he says the very foundations of morality by pointing out his wraith alike on the mere extravagances of fashion and upon breaches of the weightier matters of the law. The work was reprinted by W. B. D. D. Tarnhill in 1836, and by F. J. Furnivall in the New Shakespeare Society's issues (1879, 1882).

Stubbs, WILLIAM, historian, was born at Knaresborough, 21st June 1825, and was educated at Ripon grammar-school and Christ Church, Oxford, graduating with a classical first-class in 1848. He was at once elected to a fellowship at Trinity College, took orders, and became vicar of Navestock, Essex, in 1850. He acted as diocesan inspector of schools from 1860 till 1866, when he was appointed regius professor of Modern History at Oxford, with the year following a fellowship at Oriel. He was appointed librarian to Archbishop Longley at Lambeth in 1862, a curator of the Bodleian in 1868, rector of Cholderton, Wiltshire, in 1875, and canon residentiary of St Paul's in 1879. He was consecrated Bishop of Chester in 1884, was translated to the see of Oxford in 1889, and died 22d April 1901. Bishop Stubbs's historical work is marked by vast learning and rare

impartiality and sagacity; his style was usually somewhat dry, but he raised the standard of historical research in Britain. Of his many works the chief are *Registrum Sacrum Anglicanum*: an attempt to exhibit the course of Episcopal succession in England (1858); Mosheim's *Institutes of Ecclesiastical History*, thoroughly revised and brought down to the present time (3 vols. 1863); *Select Charters and other Illustrations of English Constitutional History*, from the earliest period to the reign of Edward I. (1870); the altogether invaluable *Constitutional History of England in its Origin and Development* down to the accession of the House of Tudor (3 vols. 1874-78); *The Early Plantagenets* in 'Epochs of Modern History' (1876); and *Seventeen Lectures on the Study of Mediæval and Modern History* (1886).

Besides these he edited, in the Records publications, of the reign of Richard I., the *Itinerarium and Epistola Cantuariensis* (2 vols. 1864-65); Benedict of Peterborough's *Gesta of Henry II.* and Richard I. (2 vols. 1867); Roger de Hovedon's *Chronicle* (4 vols. 1868-71); *The Historical Collections of Walter of Coventry* (2 vols. 1872-73); *Memoirs of Saint Dunstan* (1874); *The Historical Works of Master Ralph de Diceto* (2 vols. 1876); the *Historical Works of Gervase of Canterbury*, covering the reigns of Stephen, Henry II., and Richard I. (2 vols. 1879-80); *Chronicles of the Reigns of Edward I. and Edward II.* (1882-83); William of Malmesbury, *De Regum Gestis Anglorum* (1887-89). The prefaces to these were separately published after his death. He began with the Rev. A. W. Haddan the *Concords and Ecclesiastical Documents relating to Great Britain and Ireland*, based on Spelman and Wilkins (3 vols. 1863-78). Further lectures, on European and on early English history, were published in 1904-8. He was a corresponding member of the Institute of France, and had honorary doctorates from several universities. His letters were edited by W. H. Hutton (1904), who wrote also a Life of him (1906).

Stucco, a term applied to work in plaster of Paris (sometimes mixed with other ingredients) used for coating walls or making casts of figures. See GYPSUM, PLASTERING, CAST.

Stucken, EDUARD, German man of letters, born 18th March 1865 at Moscow, was for a time a merchant, then studied in Berlin, where he eventually settled. As a dramatist Stucken stands in the forefront of the 'new romantic' movement in contemporary German drama, his most impressive production being the cycle of five 'mysteries,' *Der Grad* (1902-16), comprising *Gaudin*, *Lauréat*, *Lanzlot*, *Mertins Geburt*, *Tristram und Ysolt*. A volume of verse, *Das Buch der Traume* (1916), was very well received, and his fame was further established by a long but clever novel, *Die weissen Götter* (3 vols. 1918-20). Since 1896, when his first play *Yrsa* appeared, Stucken has written ballads, elegies, romances, and many other plays.

Stud-book, a book containing the pedigrees of animals, especially horses. That for race-horses, edited by the officials of the Jockey Club, dates from 1808. There are stud-books for Clydesdale horses, cattle, &c., and even separate ones for colliers, fox-terriers, St Bernard dogs, &c.

Stuffing. See TAXIDERMY.

Stuhlweissenburg (Hung. *Székes Fehérvár*, Lat. *Alba Regia*), a town of Hungary, and seat of a bishop, lies in a swampy plain, 39 miles SW. of Budapest. Here from 1027 to 1527 the kings of Hungary were crowned and buried. The town was in the possession of the Turks almost continuously from 1543 to 1688. It is now greatly decayed, but has celebrated horse-fairs. Pop. 36,500.

Stukeley, WILLIAM, antiquary, was born at Holbeach, Lincolnshire, 7th November 1687, and from the grammar-school there passed in 1703 to Corpus Christi College, Cambridge. Having taken his M.B. (1709) and studied at St Thomas'

Hospital, he practised successively at Boston, London, and Grantham, meanwhile proceeding M.D., and being admitted an F.R.C.P. But in 1729 he took orders, and, after holding two Lincolnshire livings, in 1747 was presented to the rectory of St George the Martyr in Queen Square, London, where he died, 3d March 1765. His twenty works, published between 1720 and 1726, and dealing with Stonehenge, Avebury, and antiquities generally, enshrine a good deal that is curious, and have preserved much that might else have perished, but they are marred by a credulity and fancifulness which won for him the title of the 'Arch-Druid.' See his *Family Memoirs*, edited for the Surtees Society (3 vols. 1884-87).

Stupa. See TOPE.

Sturdee, Sir FREDERICK CHARLES DOVETON, British admiral (1917), born 1859, entered the navy in 1871, and wiped out a German squadron off the Falkland Islands, 8th December 1914. He died in 1925.

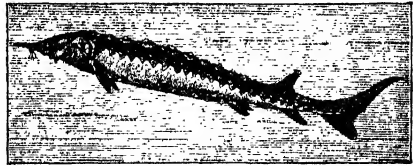

Sturdy, or the GID, affects young sheep, and sometimes young cattle, and is due to the presence within the brain of a Hydatid or bladder-worm, *Coenurus cerebralis*, which is the asexual or cystic stage of the tapeworm *Tania caninus*, mostly found in dogs. The bladder or cyst, sometimes the size of a hen's egg, or even larger, consists of an enveloping membrane, and contains a watery fluid. Upon its internal surface the membrane bears numerous white dots in groups, the heads of the future tapeworm in various stages of development. If a dog should eat the bladder-worm, e.g. in eating the head of the dead sheep, the dots will develop in its intestine into tapeworms. The ripe joints of the tapeworm pass on to the grass with the faeces; they break up and liberate ova developing within resistant shells; if these are eaten by the sheep they hatch out in the stomach as microscopic hooked embryos. These bore their way into blood-vessels and get carried to various parts of the body. They develop into bladderworms only in the brain and spinal cord. An infected sheep cannot properly seek its food, loses condition, staggers when moved, turns stupidly round almost in one spot, and usually towards the side on which the hydatid lies. The parasite and its sac may generally be removed by placing the sheep, with its feet tied, on a table or bench, searching for the softened portion of the skull, which generally overlies the hydatid, laying back a flap of skin, and introducing the trocar and canula, and, when the sac is deep-seated, cautiously withdrawing it with the help of a small syringe. Protected by a leather cap and simple water-dressings, the wound may heal and the sheep recover.

Sture, a noble family of Sweden, which furnished three successive regents to that country during the period (1470 to 1520) of its nominal union with Denmark. The first of these was STEN STURE THE ELDER (died 1503), an enlightened and far-seeing statesman, who, relying upon the peasantry, combated the pretensions of both clergy and nobility, successfully withstood the Danes, and encouraged learning by founding the university of Uppsala, introducing printing into Sweden, and inviting thither learned men. He was succeeded by his nephew, SVANTE NILSSON STURE (died 1512), who also fought bravely against the Danes; and the third regent of the family was STEN STURE THE YOUNGER (died 1520), who was mortally wounded in battle against the Danes.

Sturgeon (*Acipenser*), a genus of Ganoid fishes of the family Acipenseridae, order Chondrostei. The Chondrostei are Ganoids without ganoid scales, the skin being either naked or with bony plates, as in the sturgeon. The skull is cartilaginous, but

covered externally with bony plates belonging to the skin. The tail is asymmetrical or heterocercal, and the gelatinous notochord persists in the centre of the vertebral column throughout life. Spiracles like those of sharks and skates are present in some genera. The distinguishing features of Acipenser are these: the body is long and narrow, and the skin is provided with five longitudinal rows of bony shields, each bearing a projecting keel. One row of these bony plates is along each side of the body, one along the back, and one on each side of the ventral surface. The skin between these rows of plates is naked, but contains minute scales which give it a rough surface. The head projects into a flat, pointed snout, provided with fleshy tentacles or barbels; and on the under surface of this snout, some distance behind its extremity, is the mouth, which is without teeth, and capable of protrusion. The gill-opening is wide. There are two pairs of fins, the pelvic being situated a long way back, close to the anus. There are two median fins, one dorsal and one ventral, both near the tail. The fin-rays are jointed and flexible. Spiracles are present behind the eyes. The air-bladder communicates with the gullet. There are many species of sturgeon, all confined to the northern hemisphere. They live in the sea and great lakes, and ascend the great rivers. All are of considerable size, and supply valuable commodities, for which they are regularly captured on a large scale. These commodities are their flesh, which is palatable and wholesome, their roe (Caviare, q.v.), and their air-bladders, from which isinglass is made. The eggs are small and numerous, like those of bony fishes; there is no copulation, the ova being laid and fertilised on the bottom of the upper parts of rivers, like those of the salmon. The food of sturgeons consists of worms, crustacea, and molluscs, which they seek by routing in the sea-bottom with their snouts.

The Common Sturgeon (*A. sturio*) is the only species which occurs in British seas and rivers.

Sturgeon (*Acipenser sturio*).

The specific characters distinguishing the species are minute, consisting in the number of the bony scales, position of the fins, length of the snout, &c. *A. sturio* is sometimes taken by trawlers at sea, more often in salmon stake-nets, and in estuaries, especially in the Severn. It enters the rivers in the early part of the year for the purpose of breeding. When adult it is from 6 to 10 feet long. It occurs in the Mediterranean, western and northern Europe, and on the Atlantic coast of America, but is absent from the Black Sea and Danube, and from the Caspian Sea. In England, as early as Edward II.'s reign, the sturgeon was a royal fish, belonging to the king when captured. The Sterlet (*A. ruthenicus*) is a much smaller species, which is common in the Black and Caspian Seas, and ascends the Danube as far as Vienna. It is one of the principal objects of the sturgeon-fishery on the Volga. *A. huso* is the largest species, reaching 25 feet in length, and also belongs to the Black and Caspian Seas. *A. stellatus* is another species of these seas; it reaches 5 feet in length. Other species occur on the Atlantic and Arctic coasts of North America, in the great lakes of the St

Lawrence system, in California, and on the west coasts of the North Pacific, in China, and eastern Siberia. *A. brevirostris* belongs to the southern Atlantic coasts of the United States. The species of the great lakes of the St Lawrence is *A. rubicundus*. The species of California and the Pacific coast is *A. transmontanus*.

The most important sturgeon-fishery in Europe is that of the Volga and the Caspian Sea. The flesh of the fish is salted, and caviare and isinglass made on a large scale from the roes and air-bladder. In America sturgeon flesh is eaten fresh, and caviare is made both in Georgia and in San Francisco; but there is no great fishery in any particular district, and the manufacture of isinglass (q.v.) does not receive much attention.

Sturlason. See SNORRI.

Sturm, JOHANNES, well known as an educational reformer, was born at Schleiden, near Aix-la-Chapelle, 1st October 1507. In his fifteenth year he was sent to Liège, where he attended a school of the Brothers of the Common Life—a school so admirably organised that in his own subsequent reform of the schools at Strasburg Sturm largely followed its model. Three years later Sturm continued his studies at Louvain, then the most enlightened centre of the higher studies north of the Alps, where shortly before there had been founded a college for the teaching of Latin, Greek, and Hebrew. Besides his zeal as an educational reformer Sturm all through life had the ambition to write a Latin style framed on the best models of antiquity. It was at this time, therefore, that he began the assiduous study of Cicero, whom to the end he never ceased to read with unabated zeal. He remained some five years in Louvain.

In 1529 he went to Paris, and at first gave himself to medicine, with a view to securing a settled competence. But his natural instinct again declared itself, and he returned to the study of Cicero, on whom he gave courses of lectures in the Collège Royal. Besides lecturing on Cicero he also taught dialectics, and had for one of his students Petrus Ramus (q.v.). As a sympathiser with the new teaching in religion, identified as yet only with the name of Luther, it was at some risk that Sturm made his home in Paris. Accordingly, when a request was made to him (1536) by the authorities of Strasburg to come to their assistance in re-organising the education of their town, Sturm willingly accepted their offer. By its position on the frontiers of France and Germany Strasburg played a part of the highest importance in the political and religious history of the 16th century. Both in the religion and politics of his time Sturm took a prominent part, and on different occasions was sent on missions to France, England, and Denmark. In religion he took sides with Zwingli against Luther, with whose followers in Strasburg he was in constant controversy, which embittered all the later years of his life.

Before Sturm's settlement in Strasburg its magistrates had shown an enlightened interest in public instruction; but guided and inspired by Sturm the town became one of the most important educational centres in Europe. Two years after his arrival (1538) a new gymnasium was established, with Sturm as its rector, and at the same time boarding-houses were erected for poor students with the object of suppressing the mediæval practice of mendicancy. Elementary and secondary education were thus provided for; but it was the ambition of Sturm that the higher studies should also be within reach of every youth of Strasburg. The divided councils of the town, however, and the imply delayed Sturm's scheme till as late as 1564.

In that year was founded the Strasburg Academy, which, together with the Gymnasium, supplied a complete course of instruction in all the learning of the time. Sturm's ideal in education was 'to direct the aspiration of the scholars towards God, to develop their intelligence, and to render them useful citizens by teaching them the skill to communicate their thoughts and sentiments with persuasive effect.' In carrying out this ideal, described in his favourite phrase *pietas literata*, Sturm showed his superiority by his judicious gradation of the course of study, and by his novel and attractive methods of instruction. It is his chief praise that beyond all his contemporaries he succeeded in correlating public instruction to the moral and intellectual development of his time. It was little to the credit of Strasburg, therefore, that in his last years he was forced to leave the town through the intolerance of Lutheran zeal. Eventually permitted to return, he died on 3d March 1589. He was a voluminous writer, but, except for the light they throw on the great questions of the 16th century, his works possess no independent value.

See Charles Schmidt, *La Vie et les Travaux de Jean Sturm* (Strasburg, 1855), and German works by Laas (1872) and Kuckellahn (1872).

Stürmer, BORIS VLADIMIROVICH (1849-1917), Russian politician, found his way into high society while a student at St Petersburg University. Among his numerous political appointments he counted the presidency of the Tver Zemstvo (1892), provincial governorships, prime ministry (1916), ministry for Foreign Affairs. He died in prison after the revolution.

Sturm und Drang. See GERMANY, p. 194.

Sturt, CHARLES, explorer, was born in Bengal Presidency, 28th April 1795, went as captain of his regiment to Australia, and between 1828 and 1845 headed three important expeditions (see AUSTRALIA), from the last of which he returned blinded by hardship and exposure. He held several colonial appointments, and in 1851 received a pension. He wrote two narratives of his explorations (1833 and 1848), and died at Cheltenham, 16th June 1869. See Life by Mrs N. G. Sturt (1899).

Stuttering. See STAMMERING.

Stuttgart, the capital of Württemberg, stands in a natural basin (817 feet above sea-level) surrounded by hills, which are studded with villas, vineyards, and gardens, and crowned with woods, about 2 miles from the Neckar, and 189 by rail WNW. of Munich, 127 SSE. of Frankfurt. Except the churches, most of the public edifices date from the 19th century, and are chiefly built in the Renaissance style. The centre of the place is the Palace Square, upon or near which stand the following buildings: the new palace (1746-1807), now used as museum, &c., the old castle (16th century), two or three other palaces of the former royal family, the Königsbau (shops, bourse, concert-rooms, &c.), the theatre, the railway station (one of the finest in all Germany), the post-office, the Akademie (formerly the Carl School; now library and guardhouse), and the jubilee column (1841), and statues of Schiller and Duke Eberhard. The Collegiate Church, St Leonard's, and the Hospital Church date from the 15th century. The last two, as well as the modern church of St John, are in the Gothic style. The other chief public institutions of Stuttgart are its famous Polytechnic (with 2000 students), the High School of Music, the *Landesbibliothek* (706,000 vols., with a fine collection of over 8000 Bibles), the 'Library of the World War' (1915), museums, picture-gallery, and other collections and educational establishments. Stuttgart ranks next after Leipzig as a centre of the German book-trade. It has, moreover, active industries

connected with textiles, beer, pianofortes, chemicals, chocolate, artists' colours, furniture, wood-work, and has celebrated fairs for books, hops, horses, and cloth. The newer portion of the town is to a large extent residential. North-east from the palace lies a picturesque park with some good statuary, extending almost all the way to Cannstatt (q.v.). The latter, a popular resort and spa, about 2 miles NE., was in 1904 incorporated in the city of Stuttgart. Hegel and Hauff were born at Stuttgart, and Schiller studied at the Akademie. Pop. (1875) 107,573; (1910) 286,218; (1925) 337,199. Stuttgart owes its name and origin to a stud-farm of the early Counts of Württemberg, and has been the capital since 1482.

Stuyvesant. PETER, governor of New York, was born in Holland in 1592, became governor of Curaçoa, and lost a leg in the attack on St Martin, and in 1646 was appointed captain-general of the New Netherlands. He proved a vigorous but arbitrary ruler, a rigid Sabbatarian, and an indignant opponent of political and religious freedom. Yet he did much for the commercial prosperity of the city, which received its name of New Amsterdam in 1653, and which he would fain have held against the English in 1664, when it became New York. He afterwards lived at his farm, the 'Great Bonwerie,' whose name survives in one of the older streets of the city which soon covered it; and there he died in 1672.

Stye. See EYE.

Style, OLD AND NEW. See CALENDAR.

Stylites, SIMEON, the earliest and most famous of the ascetics called Pillar-saints (Gr. *stylites*), had been a monk, and had lived, in the beginning of the 5th century, in extreme seclusion in his Syrian monastery for nine years, without ever moving from his narrow cell. Increasing in enthusiasm he withdrew to Telussu, near Antioch, where he established himself on the top of a pillar 72 feet high, and only 4 feet square at the top. Here he spent thirty years. During the day he preached to the crowds who gathered at the foot of his pillar; and his admonitions to emperors and empresses were accepted with humility. The fame of his sanctity brought crowds of pilgrims from the most distant countries to see him; and the admiration of his fasting and other austerities is said to have converted many pagans to the church. He died on his pillar in 459, aged seventy-two, and was buried with the greatest pomp at Antioch. A disciple of Simeon, named Daniel, succeeded to his reputation for sanctity, and to his mode of life, which he maintained for thirty-three years, in the still more trying climate of the shores of the Bosphorus, about 4 miles from Constantinople. The emperor at length insisted on a covering being placed over the top of the pillar, and Daniel survived till the year 494. In Syria there were many pillar-saints as far down as the 12th century; but in the west Daniel is all but a solitary example. A monk named Wulfailich, near Troves, attempted the pillar-life in the 6th century, but the neighbouring bishops compelled him to desist and destroyed his pillar.

Styptics (Gr. *styptikos*, 'astringent') are agents employed in Surgery for the purpose of checking the flow of blood by application to the bleeding orifice or surface. See BLEEDING.

Styracaceæ, a family of dicotyledons close akin to Sapotaceæ and Ebenaceæ, distinguished from the former by absence of latex, from the latter by having hermaphrodite flowers. For *Styrax*, the principal genus, see STORAX.

Styria (Steiermark), a province of the Austrian republic, enclosed by the provinces of Carinthia,

Salzburg, Upper Austria, Lower Austria, Burgenland, and bordered on the south by Yugoslavia. Its area is 6323 sq. m., pop. 980,000. Styria is a mountainous country, traversed in all parts by ramifications of the Alps. The Mur flows eastward through the middle of the province to Bruck, then turns abruptly south to join the Drava; while the Enns skirts the north-west boundary. The climate is variable, but generally raw and cold in the northern and more mountainous portion, though milder in valleys. Forests of varied character cover half of the area; one-fourth is meadow and pasture; and the rest is mostly under cultivation, producing oats, maize, rye, potatoes, roots for cattle, flax, wine; very little is unproductive. Cattle are raised on the high grounds and horses bred in the Enns valley. The chief wealth of the country, however, lies in its mineral products, especially iron and lignite; the secondary minerals include salt, coal, graphite, zinc, magnesite, &c. The chief industries are connected with the production of iron and steel, and their manufacture into machinery, locomotives, agricultural implements, wire, and so forth. The ample water power allows of numerous electrical works. There are also manufactures of chemicals, paper, cloth, gunpowder, beer, tobacco, glass, &c. Styria was anciently divided between Noricum and Pannonia, and in the end of the 6th century was colonised by the Wends (Slavs). In 1056 it was separated from Carinthia and made a separate margraviate; and in 1192 it was joined to the Austrian crown, having a few years previously been made a duchy. The duchy was terminated in 1918. Styria became a federal province of the Austrian republic, but was much curtailed, its southern portion, amounting to 2300 sq. m. or about one-quarter of the whole, being allocated (1920) to Yugoslavia (see SERBIA).

Styx (Gr. *stygēin*, 'to hate'), one of the rivers of Hades—the tenth part of the waters of Oceanus—flowing round it seven times with dark and sluggish stream, across which Charon ferries the shades of the departed. The nymph of this stream was the daughter of Oceanus and Tethys, and she first, together with her children, came to the help of Zeus against the Titans. For this service they were taken to Olympus, and she herself became the goddess by whom the most solemn oaths of the immortals were sworn. When such an oath was taken Iris brought some of her sacred water in a golden cup, and whoso swore falsely by it lay speechless and breathless for a year, and was banished nine from the councils of the gods.—A rocky stream falling into the Crathis in the north-east of Arcadia bore this name, the scenery around it being fittingly weird and desolate.

Suabia. See SWABIA.

Suaheli. See SWAHILI.

Sua'kin, or more correctly SAWAKIN, a seaport of the Red Sea, stands on a small rocky island in a bay on its west side, and is the principal outlet for the commerce of Nubia and of the countries of the Sudan beyond. The island-town is connected with the settlement of El-Keff on the adjacent mainland by a causeway. There are industries in silver ornaments, knives and spear-heads, and leather-work. Here some 6000 or 7000 pilgrims embark every year for Mecca. The Egyptians occupied this port when they extended their power over the Sudan; and in its vicinity several battles were fought between the allied Egyptians and English against the fanatical followers of the Mahdi. The railway to Berber, opened in 1906, connects with the Khartum line. Pop. 8000.

Suarez, FRANCISCO, a philosopher and divine of the Roman Catholic Church, was born at Granada on 5th January 1548. As a youth he was

so backward that he had considerable difficulty in gaining admission to the order of the Jesuits. But his mind ripened rapidly and developed in some respects unusually high qualities. During the course of his career he taught theology at Segovia, Valladolid, Rome, Alcalá, Salamanca, and Coimbra. His theology was a modification of that of Molina (q.v.); he held that in the case of the elect there is a peculiar grace granted, specially adapted to their several individual natures. In formal scholastic philosophy he steered a middle course between realism and nominalism. The most notable of his books were what may be termed the earliest foreshadowing of the modern doctrine of international law (*Tractatus de Legibus ac Deo Legislatore*) and a treatise condemning the extravagant pretensions to kingship put forward by James I. of England. This latter (*Defensio Catholica Fidei*) was written in 1613 at the command of the pope. Suarez died at Lisbon on 25th September 1617. His works were published in 23 vols. at Mainz and Lyons in 1630 *et seq.*, and in 29 vols. at Paris in 1859. There is a Life of him by Deschamps (Perpignan, 1671), and another by Werner (2 vols. Ratishon, 1861).

Subahdar was, under the Mogul government, the title of a governor of a province. It now designates a native officer in the army in India, holding a rank equivalent to that of captain, but subordinate to the European officers.

Subiaco (anc. *Sublaqueum*, i.e. below the lakes of Nero's villa, which was situated in the wild Anio gorge opposite to the monasteries), a city of Italy, lies embosomed in hills beside the Anio, 47 miles E. by N. from Rome, and was the cradle of the Benedictine order and the place where the printing-press was first set up in Italy (1465). There are two monasteries dating from the 6th century, founded by St Benedict himself, one of which (Santa Scolastica) contains a small but valuable library, and has fine cloisters in the Cosmatesque style, whilst the other was built into and over the cave in which St Benedict lived, and contains interesting and important paintings of the 13th-15th centuries, including a contemporary portrait of St Francis of Assisi. The city was greatly favoured by Pope Pius VI.: he enlarged its castle (built 1068), erected a church, &c. Pop. 9000.

Sub-lieutenant. See LIEUTENANT.

Sublimation is a chemical process similar to distillation, but differing from it in the nature of the substances to which it is applied. While in distillation *liquids* are converted by the agency of heat into vapour, which is condensed in the liquid form usually by the cooling action of water, in sublimation *solid* bodies are reduced by heat to the state of vapour, which reassumes the solid form on cooling. Sublimation is usually conducted in a single vessel of glass or iron, the product being deposited in the upper part of it in a solid state, while the impure residue remains at the bottom; but in the case of sulphur the vapour is condensed on the walls of a large chamber. Iodine affords a good example of sublimation. On gently heating the lower part of a Florence flask containing a little of this substance a purple vapour rises, which almost immediately condenses in small brilliant dark purple crystals in the upper parts of the flask, while any impurity that may be present remains at the bottom. Amongst the substances obtained by this process, and employed in the Pharmacopœia, are arsenious acid, benzoic acid, corrosive sublimate, and sublimed sulphur.

Submarine Mines. See MINES (MILITARY).

Submarine Navigation. When the Diving-bell (see DIVING) had shown that air for respiration can be supplied to persons in adequately arranged vessels under water, ingenious men began to speculate on the possibility of navigating closed ships or boats in similarly exceptional circumstances. The first submarine boat on record was constructed in the beginning of the 17th century by a Dutchman named Cornelius Drebbel, or Drebbelle. She was propelled by oars, and was tried in the Thames by order of James I. She carried twelve rowers, besides passengers. This vessel is alluded to in Robert Boyle's *New Experiments, Physico-Mechanicall, touching the Spring of the Air, &c.* (Oxford, 1660). Pages 363-365 of this curious work contain an account of Drebbel's experiment, and state that he accounted his chief secret to be 'the composition of a liquid that would speedily restore to the troubled air such a proportion of vital parts as would make it again for a good while fit for respiration.' The composition of this liquid for enabling the same air to be used again and again was never made public. Bishop Wilkins, who also favoured some other whimsical projects, devoted a whole chapter of his *Mathematicall Magick* (1648) to a dissertation 'Concerning the possibility of framing an Ark for Submarine Navigation.' He here recites the difficulties of the scheme, but evidently considers them not insurmountable; and afterwards he enlarges upon its advantages, in privacy, security from pirates, storms, ice, &c., in naval warfare, philosophical experiments, discoveries, &c. In 1774 an inventor named Day lost his life in an experimental descent in Plymouth Sound in a vessel of about 50 tons burden. One of the most successful machines contrived for submarine navigation was that of Bushnell of Connecticut, which was projected in 1771, and completed in 1775. Bushnell's chief object appears to have been the introduction of submarine warfare. His vessel was propelled by screws, somewhat resembling those now in use for steam-vessels, and there was sufficient air to last for half an hour. In 1800 Robert Fulton, also an American, while residing in France constructed a submarine boat, of which he made many trials, some of them at the expense of the French government, on the Seine, at Brest, and at Rochefort. Compressed air was used for respiration, and he remained at a depth of 25 feet for four hours, propelling the boat in any direction; he also successfully attached a torpedo containing gunpowder to the bottom of an old vessel lying in Brest harbour, and blew her up. The vessel patented in 1859 by Mr DeLucey of Chicago was egg-shaped in transverse section, and diminished nearly to a point at each end. It had two iron tanks in the interior; one had air pressed into it by an air-pump; the second contained water. The engineer of the boat, by pumping water into or out of the second tank through the action of the air in the first, could raise or lower the boat to different depths in the water. In 1863 the Confederates in Charleston made use of a submarine boat against the blockading Federal squadron. This boat, called a 'David' after her inventor, was built of boiler-plates and propelled by hand by eight men at a maximum speed of four knots; two side-rudders were used for sinking and raising the boat when in motion; she was cigar-shaped, and when advancing to attack her top was just on a level with the surface of the water; three trial trips were made, and each time she sank and failed to rise, the crews perishing before they could be rescued; the fourth trial, however, was successful, and passing out of

the harbour she succeeded in blowing up the *Housatonic*, but could not get clear, and was carried down by the *Housatonic*. Several of these 'Davids' were afterwards constructed by the Confederates, but none of them again succeeded in inflicting any serious damage upon the Federal ships.

Nordenfelt's boats, tried in 1886-87 at Stockholm, Constantinople, and Southampton, seemed at first to promise well; but to France belongs the credit of making submarine boats a real factor in naval warfare. In 1881 M. Goubet designed a small submarine boat, and in 1885 an improved *Goubet* which was 16 feet 5 inches in length, the motive power being electricity. Submersion was effected by admitting water into tanks, which could be expelled again by means of a pump, while an attached safety weight could be immediately released. A torpedo was carried outside, and the speed attained was about six knots. Successful experiments led the French Admiralty to have the *Gymnote* constructed at Toulon in 1888; she was 56 feet 5 inches long, with a displacement of 30 tons, her motive power being electricity stored in accumulators, which gave her a radius of 32 miles at 8 knots. Her trials decided the French authorities to have more vessels built, and by 1901 there were some eleven completed.

In 1901 the English Admiralty took action, and gave orders to the firm of Vickers, Maxim, and Sons, of Barrow, to construct five of the *Holland* type, so called after their designer, an American engineer, who constructed several for the U.S. government. These first five boats were 63 feet 4 inches long, with a beam of 11 feet 9 inches. Their displacement, when submerged, was 120 tons (salt water); their surface speed, with the engine developing 190 i.h.p., was about 12 knots; the submerged speed with 70 electric i.h.p. was from 7 to 8 knots, and they had a sufficient petrol storage to give a radius of action of about 350 miles. The surface motive power was derived from a 4-cylinder gasoline engine; when submerged, and for diving, the dynamo used for charging the accumulators became the motor, and was driven by the electricity previously stored in the accumulators. In addition to the propelling screw, the boats were fitted with two horizontal rudders, by the manipulation of which the boat was made to dive. The armament consisted of one torpedo-tube in the bow, five torpedoes being carried. When a torpedo was discharged, 'compensating tanks' were automatically flooded with water to exactly the same weight, so that the poise of the vessel was preserved. The later pattern boats have a displacement of 1800 tons, with a surface speed of 24 knots and a submerged speed of 9½ knots.

There are two distinct types of submarine vessel—the submarine proper and the submersible. The latter type is used universally by the navies of the world, and during the Great War the Germans relied almost exclusively on their submarine warfare to compel the British to make peace. The submarine campaign was energetically carried out against the allies, and the losses sustained by them were enormous.

Submersibles are forced under water: their surface buoyancy is reduced to almost a minimum by means of water, which is admitted into ballast-tanks, and they are then dived by means of hydroplanes and diving rudders. The thrust of these blades accomplishes and maintains the state of submersion, assisted by the under-water motive power, which is electricity stored in accumulators.

The submersible has two distinct motors—the gasoline or steam engine for surface running, and electric motors for submerged running. The original disadvantage of the submersible—namely, its inability to submerge quickly—has been com-

pletely overcome, and in the British E type these boats were able to submerge in under a minute when running at 12 knots on the surface.

The under-water endurance of a submarine is limited by the capacity of its electric accumulators and, to a certain extent, the purity of the air. In the Great War, patrolling submarines were submerged, during the summer months in the North Sea, about twenty hours out of twenty-four, the hours of darkness being used for charging the electric batteries.

By constant practice a high standard of efficiency can be maintained, ensuring thereby a large percentage of hits by torpedoes fired from submarines, such difficulties as defective periscopes and torpedoes having been overcome in recent years.

The aim of every submarine commander is to deliver his attack unseen; but this is extremely difficult in calm weather, when the wash of the periscope is easily distinguishable at 1500 yards. With the vast improvements that have been introduced in recent years both in the construction of submarines and torpedoes, the submersible has proved itself to be a very strong weapon in the hands of the weaker naval power.

The damage inflicted by Germany on the allied trade during the Great War was accomplished almost entirely by submarines and submarine minelayers, these latter being constructed about a year after the war had commenced.

Submarine construction advanced tremendously during the Great War; and, previous to the signing of the armistice, the British Admiralty produced a submarine of 1600 tons surface displacement, with a speed of 16 knots, and mounting a 12-inch gun.

The German government produced two submarines for commercial use, named the *Brenen* and *Deutschland*, these being employed running cargoes to American ports before the United States entered the war. Though *Deutschland* made two voyages, it was not a commercial success; *Brenen* was lost on her first voyage, but later more were built. These were converted into submersible cruisers, with 6-inch B.L. guns.

During the Great War, 1914-18, loss of tonnage due to enemy action was mostly due to submarines: British, 9,031,828 tons; foreign, 6,021,958 tons—total world loss, 15,053,786 tons. As to submarines themselves, the British lost about 57; the Germans about 220. Towards the close of the war the British anti-submarine arrangements were so much improved that the German submarines were much demoralised.

Subotica (Hung. *Szabauka*, Ger. *Theresopol* or *Maria-Theresopol*), formerly a royal free town of Hungary, now a frontier town of Yugoslavia, stands in the Bačka region on the plain that lies between the Danube and the Theiss, 106 miles S. by E. of Budapest by rail. It is an important railway junction and the centre of a rich agricultural district, with a trade in wheat, cattle, skins, wool, fruit and tobacco. A Law School was founded in 1920. Pop. (1881) 61,367; (1921) 101,857.

Subpena, in English law practice, means the writ or process by which the attendance of a party or witness in a court of justice is compelled. It is a writ in the king's name commanding him to lay aside his business and all excuses, and attend at the time and place indicated, under a penalty. If the person summoned do not attend and has not a good legal excuse, such as dangerous illness, he may be sued in an action of damages or committed to prison.

Subsidence. See UPHEAVAL.

Subsidies. See CUSTOMS DUTIES, EDWARD I.

Substance is a term which has played a great part in philosophical and theological discussion.

It occurs first in the Aristotelian enumeration of categories, where *docta* is in a manner opposed to the other nine categories of attribution and relation. This contrast is expressed in the correlation of the Latin terms *substance* and *accident*. Substance is defined as that which exists *per se*, whereas attributes or accidents exist *in alio*. The substance, in other words, is regarded as an independent existence, a permanent subject of which the accidents are predicated, and to which they belong as its qualities or states. Individual things were thus treated by Aristotle and the scholastics as existing *per se*; they are, in the Aristotelian phrase, 'the first substances.' To the objection which readily occurs that God alone is in this sense substance—i.e. truly self-subsistent—they replied by the distinction between *per se* and *a se*. If the world is not to be resolved into a flux of accidents, created substances must exist *per se*; but God alone exists *a se* or absolutely. The same distinction—between created substances and God as the one absolutely independent substance—reappears in Descartes, but is repudiated by Spinoza, who thus reaches his completely pantheistic doctrine of the *unica substantia*. In English philosophy the aspect of substance made most prominent is that of an underlying 'substratum' (the Greek *ὑποκείμενον*) or unknown 'support' of the qualities we know. Locke, like Descartes, believed in two classes of substances, material and spiritual; but the negative criticism of Berkeley was brought to bear against the first class, while Hume directed the same battery against the spiritual substances which the bishop had spared, and thus pulverised the world into unsupported accidents. All our perceptions, Hume declares, 'may exist separately, and have no need of anything else to support their existence.' The criticism, however, which is valid against the peculiar form which the doctrine of substance had assumed in Locke ignores the really indispensable character of the conception. The notion of substance as something over and above the qualities—an inaccessible somewhat, hidden behind the qualities instead of being revealed by them—is undoubtedly false. But a pure phenomenalism can yield no theory of knowing or being. The world, as it has been said, is not a flight of adjectives; qualities do not fly loose; they are necessarily unified in a substance or subject. In recent philosophy the misleading idea of a substratum reappears in the Kantian theory of the unknowable thing-in-itself, which in turn develops into the characteristic doctrine of modern agnosticism.

Succession, a term used technically in Roman and Scots law (but not in English law) to denote the taking of property by one person in place of another. The order of succession in Roman and Scots law differs in several respects from that in English law. See **HEIR, KIN (NEXT OF), EXECUTOR, HUSBAND AND WIFE, LEGITIM**. For legacy and succession duties, see **LEGACY AND DEATH DUTIES**. For **APOSTOLIC SUCCESSION**, see under that heading.

Succession Acts. From a comparatively early period in English history parliament occasionally exercised the power of limiting or modifying the hereditary succession to the throne. The first instance of such interference occurred in the case of Henry IV.; and parliamentary interposition was subsequently exercised in the case of Henry VII. and in regard to the immediate successors of Henry VIII. The respective rights of James I., Charles I., and Charles II. were acknowledged by parliament. The revolution of 1688 was founded on the so-called abdication of the government by James II. The Convention

bestowed the crown on William and Mary for life, and regulated the claims of Anne. In view of the impending extinction of the Protestant descendants of Charles I. the crown was settled by 12 and 13 Will. III. chap. 2, in the event of the death of William and Anne without issue, on the next Protestant line, according to the regular order of succession—viz. the descendants of the Electress Sophia of Hanover, granddaughter of James I.; and it was at the same time enacted that whoever should hereafter come to possession of the crown should join the communion of the Church of England as by law established (see **GEORGE I., HANOVER**). This is the latest parliamentary limitation of the crown; but the right of parliament to limit the succession was secured by 6 Anne, chap. 7.

Succession Wars is the general name given to contests which took place in Europe during the 18th century on the extinction of certain dynasties or ruling houses. Four such wars are usually enumerated—that of the Spanish succession (1701–13), of the Polish succession (1733–38), of the Austrian succession (1740–48), and of the Bavarian succession (1777–79). The first and third alone are of sufficient general historical interest to be noticed here.

(1) **WAR OF THE SPANISH SUCCESSION**. Charles II., king of Spain, having died without direct descendants in November 1700, claims were raised to the vacant throne by the husbands of his two sisters, Louis XIV. of France, who had married the elder, and the Emperor Leopold I., who had married the younger. Both these monarchs were also themselves grandsons of Philip III. of Spain; but neither desired the Spanish crown for his own head. Louis put forward his grandson Philip of Anjou; whilst Leopold advocated the claims of his second son, the Archduke Charles. The Electoral prince Joseph of Bavaria, grandson of the Emperor Leopold, was the heir originally designated in King Charles's will, but he died in the beginning of 1699. Both Louis XIV. and his wife had nine years before solemnly renounced the crown of Spain for themselves and their heirs; nevertheless, after Joseph of Bavaria died the agent of Louis XIV. induced Charles of Spain to nominate Philip of Anjou as his successor. Three months after the Spanish prince
and was crowned as Philip V.; and his accession was at first recognised by all the European powers except the emperor. Louis, however, soon provoked the United Netherlands and England, and they joined Austria for the purpose of armed opposition to France.

Hostilities were begun by Prince Eugene in Italy in 1701; and in the following year the conflict raged not only in Italy but also in the Netherlands and in Swabia. At first the allies were victorious all along the line: Marlborough took the fortresses on the Meuse and overran the electorate of Cologne; and the Margrave of Baden had the good fortune to drive back the most redoubtable of the French commanders, Villars, who had crossed the Rhine from Alsace. But the aspect of things was altered in 1703 by Villars, in conjunction with the Elector of Bavaria, penetrating as far as Tyrol and capturing Passau, whilst the imperialists in Italy were more than held in check by Vendôme. But in the campaign of 1704 Marlborough and Eugene, acting in concert, inflicted a crushing defeat upon their opponents at Blenheim (q.v.) and drove them back into France. Two years later the forces of Louis were compelled to withdraw from the Netherlands owing to Marlborough's great victory of Ramillies and his capture of the principal Flemish towns. At the same time Eugene and his relative the Duke of Savoy routed the French near Turin

and swept them out of North Italy. Meanwhile the war had extended to the Iberian peninsula. The king of Portugal declared for the allies, and Archduke Charles made himself master of Catalonia, and even for a time held possession of Madrid. The English captured Gibraltar in 1704; but they and the Portuguese sustained a severe defeat from the Duke of Berwick (commanding the French forces) at Almanza in 1707. In this latter year Louis, feeling the severity of the strain, opened negotiations for a settlement. But the allies, having the upper hand, thought to humble him yet more, and the war went on.

An attempt of Vendôme and the Duke of Burgundy to reconquer the Spanish Netherlands in 1708 was frustrated by Marlborough and Eugene, who routed them at Oudenarde; and in the next year they defeated at Malplaquet the hitherto invincible Villars. Yet just when the fortunes of Louis seemed to be at their worst, circumstances intervened in his favour. In England the Whigs were supplanted by the Tories, who voted for peace; and in Austria the Emperor Leopold died, and was succeeded by the Archduke Charles. Accordingly the war languished, and, Philip V. having pledged himself that the crowns of Spain and France should not be united, all the allies, except the emperor, signed the treaty of Utrecht (q.v.) on 11th April 1713. The emperor, too, was brought to terms after Villars had overrun the Palatinate and Baden, and he signed peace at Rastatt (7th March 1714), whereby he acknowledged Philip as king of Spain, and became himself the ruler of the Spanish Netherlands, Naples, Milan, and Sardinia.

Paris, 1886); Von Noorden, *Der Spanische Erbfolgekrieg* (3 vols. Düsseldorf, 1870-82); Arneth, *Prinz Eugen von Savoyen* (3 vols. Vienna, 1858); and the articles EUGENE, MARLBOROUGH, PETERBOROUGH, VILLARS, &c. in this work.

(2) WAR OF THE AUSTRIAN SUCCESSION. The Emperor Charles VI. died in 1740, leaving his hereditary dominions—Bohemia, Hungary, and the archduchy of Austria—to his daughter Maria Theresa. She was at once beset by enemies, eager to profit from the presumed weakness of a feminine ruler. The Elector Charles Albert of Bavaria, who had refused his signature to the Pragmatic Sanction (q.v.), demanded the imperial crown as the descendant of the Emperor Ferdinand I., and he was backed up by France and Spain. Augustus of Saxony and Poland advanced his claim as being the husband of the eldest daughter of the Emperor Joseph I. Frederick the Great of Prussia seized the opportunity to wrest Silesia, which he greatly coveted, from the crown of Austria. The Bavarians and the French (under Belleisle) invaded Bohemia, and crowned the elector king of that country at Prague on 19th December 1741. About two months later he assumed the imperial crown at Frankfurt-on-Main; yet on the very next day his own capital (Munich) was occupied by the Austrian general Khevenhüller, who, assisted by the high-spirited Hungarians, had advanced up the Danube, and now speedily overran Bavaria. A few months later the empress-queen bought off her most dangerous antagonist, Frederick, by giving up to him Silesia. At this time, too, Augustus of Saxony, who had at first made common cause with the French and the Bavarians, withdrew from the contest and made peace with Maria Theresa. In the end of 1742 the Austrians were forced out of Bavaria and the French evacuated Bohemia. The English, who from the first paid a substantial subsidy to Austria, took up arms on her behalf in this same year, and in 1743 defeated the French

at Dettingen in Bavaria. In this year the Austrians repossessed themselves of the Elector Charles Albert's dominions. Saxony now joined the allies and took the field against his former associates. On the other hand, Frederick renewed hostilities and invaded Bohemia; but after a short interval he was once more willing to make peace. About this juncture Charles Albert died, and his son and successor abandoned his father's pretensions to Maria Theresa's dominions. This left France to carry on the struggle alone. But whilst Austria had the better of the war in Italy, Marshal Saxe captured several of the Flemish fortresses, won the victories of Fontenoy (1745), Rocoux (1746), and Lawfeldt (1747), and reduced the Austrian (formerly Spanish) Netherlands. Peace was at length concluded at Aix-la-Chapelle on 18th October 1748, things remaining pretty much *in statu quo*, except that Frederick was allowed to retain Silesia.

See ARNETH, *Geschichte Maria Theresias* (10 vols. Vienna, 1863-79); and MARIA THERESA, SAXE, &c.

Succinic Acid derives its name from its having been originally found in amber (Lat. *succinum*). Succinic acid occurs as a natural constituent not only in amber, but also in the resins of many of the pine tribe, in the leaves of the lettuce and wormwood, in unripe grapes; and in the animal kingdom it has been detected in the fluids of hydatid cysts and hydrocele, in the parenchymatous juices of the thymus gland of the calf, and of the pancreas and thyroid gland of the ox. Succinic acid is convertible into tartaric acid, and conversely.

Succubus, Succuba. See DEMONOLGY.

Succulent Plants, a descriptive phrase applied to the Crassulaceae, Cactaceae, Aizoaceae, some Euphorbiaceae, Liliaceae, &c.—xerophytes that store water in their leaves or stems. See ECOLOGY.

Suchet, Louis-Gabriel, Duc d'Albufera, and marshal of France, was born, son of a silk manufacturer, at Lyons, 2d March 1770. At twenty-two he volunteered into the cavalry of the Lyons national guard, next fought in Italy, and by his conspicuous courage and ability at Lodi, Rivoli, Castiglione, Arcola, and a hundred battles, had risen by 1798 to be general of brigade. He added to his reputation in Egypt and again in Italy, served as general of division under Joubert in 1799, and the year after was second in command to Masséna. He covered himself with glory by checking a vastly superior Austrian force under Melas (1800), and so preventing the invasion of the south of France. He took a distinguished part in the campaigns against Austria (1805) and Prussia (1806), and was subsequently (April 1809) appointed generalissimo of the French army in Aragon—his first independent command. By marvellous tact no less than military skill he reduced this stubborn province to complete submission within two years. He conquered at Mavia and Lerida, and took Tortosa and Tarragona, for which he was rewarded with a marshal's baton. In 1812 he destroyed the army of Blake at Sagunto, and on the 9th January of that year captured Valencia, earning the title of Duke of Albufera. The details of his five Spanish campaigns have been well given by him in his *Mémoires sur ses Campagnes en Espagne* (2 vols. Paris, 1829-34). He was created a peer of France by Louis XVIII., but joined Napoleon after his return from Elba, and was charged with the defence of the south-west frontier. Deprived of his peerage after the disaster of Waterloo, he did not return to court till it was restored in

1819. He died at the château of Saint-Joseph, near Marseilles, 3d January 1826. O'Meara and Las Cases tell us that of his generals Napoleon ranked Masséna first and Suchet second.

Sucking-fish, a name sometimes given to the Remora (q.v.) or Echeueis, which has a dorsal sucker, and to other fishes which have a sucker formed by the union of the ventral fins—e.g. *Cyrtopomus lumpus*, the Lumpsnucker (q.v.). To the members of the carp-like Catostomidae, almost exclusively confined to the rivers of North America, the name sucker is also applied, in allusion to their mode of sucking up their food, which consists of small aquatic animals.

Suckling, SIR JOHN, poet, was born at Whitton in Middlesex, and baptised February 10, 1609. He was of good family on both sides, and his maternal uncle, Sir Lionel Cranfield, became Earl of Middlesex; his father held office as a secretary of state and comptroller of the household under James I., and was made privy-councillor by Charles I. Suckling may have been at Westminster, as Aubrey says, but certain it is that in 1623 he entered Trinity College, Cambridge, five years later went on his travels abroad, and served for some time in Germany under Gustavus Adolphus. He returned about 1632, and soon became 'the darling of the court,' distinguished before all by his wit and prodigality. An inveterate gambler, he spent his days and nights at cards and bowls, his intervals divided betwixt gallantry and verse-making. In April 1635 he appeared before the Star-chamber for breaking the statute passed in the eighth year of Charles to require all landowners to spend some time on their estates. To aid the king against the Scots he raised a troop of 100 horse, and equipped them so handsomely that it is said to have cost him about £12,000. They rode north with the king, but shared the shame of the rout before the Scots at Duns. The lampoon by Sir John Mennes has commemorated the cowardice of Suckling and his gay cavaliers, but in reality they behaved no worse than the rest of the royal army. Suckling was returned to the Long Parliament for Bramber, joined in the abortive plot to rescue Strafford from the Tower, and in more desperate plots still against the liberties of the kingdom by means of French and Irish troops, and his schemes being discovered he fled for safety to the Continent. Impoverished and disgraced, he is believed to have poisoned himself at Paris before the close of 1642. The works of Suckling consist of four plays, *Aglaure*, *The Goblins*, *Brennorcliff*, and *The Sad One*, now utterly forgotten; a prose treatise entitled *An Account of Religion by Reason*; a few Letters, written in an artificial style; and a series of miscellaneous poems, beginning with *A Sessions of the Poets*, published in 1637, which is original in style, and happily descriptive of the author's contemporaries. But the fame of Suckling rests on his songs and ballads, which at their best are inimitable for ease, gaiety, and grace. 'The well-known *Ballad upon a Wedding* is an exquisite masterpiece of sparkling gaiety and felicity of phrase; and his lyrics 'I prithee send me back my heart,' 'Why so pale and wan, fond lover?' are amongst the triumphs of English verse.

See the Rev. Alfred Suckling's *Selections, with a Life* (1836), reproduced by W. C. Hazlitt, with a few additions (1874); also the Memoir prefixed to F. A. Stokes's edition (New York, 1885); and A. H. Thompson's edition of the *Works in Prose and Verse* (1910).

Sucré. See CHUQUISACA.

Sucré, ANTONIO JOSÉ DE (1793-1830), born in Cumana, Venezuela, was Bolívar's lieutenant and first president of Bolivia (1826).

Sucrose. See SUGAR.

Sudamina, or MILIARY ERUPTION, one of the vesicular diseases of the skin, is associated with profuse sweating, though it occasionally occurs in a dry skin; the second name refers to the size of the vesicles, which do not exceed those of a millet-seed. The vesicles, most abundant on the neck and trunk, and sometimes attended with itching, almost always occur in association with febrile disorders, particularly acute rheumatism, but give rise to little irritation.

Sudan, or SOUDAN, the Arabic equivalent (*Belad es Sudan*—i.e. 'Land of the Blacks') of Negroland or Nigritia, a geographical term which in its widest sense embraces the vast region of Africa that stretches from the Atlantic to the Red Sea and the Abyssinian highlands, and from the Sahara and Egypt proper in the north to the Gulf of Guinea, the central equatorial regions, and the Albert and Victoria Nyanzas in the south. This is the home of the true Negro race, though there are various other pure and mixed elements in the population derived principally from Hamitic and Semitic (Arab) stocks. The Sudan in this sense falls naturally into three divisions: (1) *Western Sudan*, comprising the basins of the Senegal, Niger, Benue, and other rivers draining to the Atlantic, and including the political regions known as the French Sudan (see SENEGAMBIA), Sokoto (q.v.), and others; (2) *Central Sudan*, including the basins of the rivers draining into Lake Tsad, and covering the countries of Bornu (q.v.), Bagirmi (q.v.), Kaueri, Wadai; (3) *Eastern Sudan*, the rest of the Sudan area east of Wadai, mainly the basin of the Middle and Upper Nile; and this region, also called the Egyptian or Anglo-Egyptian Sudan, has since the events of 1882-98 so largely monopolised English attention as to be, quite unhistorically, called the Sudan. The Sudan extends southwards from the frontier of Egypt to Uganda and the Belgian Congo, a distance of 1270 miles, and stretching from the Red Sea to Wadai in Central Africa, with an area of 985,000 sq. m. and a pop. (which under the Mahdi declined from 9,000,000 to 2,000,000) estimated at nearly 6,000,000. Massowah, formerly Egyptian, now belongs to the Italian colony of Eritrea. Harar has been given to Abyssinia, while Zeila and Berbera are included in British Somaliland. The chief towns are Khartoum, the capital, Halfa, Berber, Snakin, Kassala, Atbara, and El Obeid.

All the regions actually watered by the Nile and its great tributaries possess highly fertile soil, capable of yielding immense quantities of cotton, durra, indigo, sugar, rice, maize, tobacco, fruits. Cotton, first introduced experimentally in 1911, promises to be the great staple of the Sudan. Irrigation is successfully practised, especially in the Gezira and north-eastern districts. The Sennar Dam was completed in 1925. The central and southern provinces are well suited for rain-grown cotton, which promises to become of very great importance. Ivory, ostrich-feathers, rubber, salt, cloth, gums, iron, gold, honey, wax, and hides are also articles of internal traffic and foreign trade. There is a railway from Khartoum to Wady Halfa; and from Atbara, near Berber (on the other line), to Port Sudan, 30 miles north of Snakin (1905).

A line (1925), 215 miles long, connects Kassala with Haiya, a point on Atbara-Port Sudan line. A convention between the British and Egyptian governments in 1899 placed the administration of the Sudan in the hands of a governor-general appointed by Egypt with the approval of Great Britain. Since 1910 he has been aided by a council. The country is divided into fifteen provinces under governors. The High Court of Justice

sits at Khartum, and there are minor courts in the provinces. There are also Mohammedan law courts for administration of Moslem religious law, and native chiefs' courts.

The Egyptians established themselves at Khartum in 1819, and during the next fifty years gradually extended their power over the provinces lying west and south of that city, and were more especially active during the third quarter of the century. In 1874 Dar-Fâr was conquered with help of Zebehr Pasha, a noted slave-hunter, who, not receiving the reward he expected, provoked insurrections there and in the Bahrel-Ghazal province (1877-79), which were successively crushed by Gordon and Gessi. But in 1882 the Mahdi (q.v.) again raised the flag of revolt, and preaching a religious crusade, overpowered the distant Egyptian garrisons, annihilated the Egyptian forces led by Hicks Pasha, surrounded Emin Pasha (see SCHNITZER) in the Equatorial Province, and shut up Gordon (q.v.) in Khartum; while his lieutenant, Osman Digna, after defeating the Egyptian army commanded by Baker Pasha, prevented the English from penetrating into the interior from Suakin and the Red Sea. Gordon's mission ended in disaster, and with the fall of Khartum, Egyptian influence in the Sudan seemed at an end. Anarchy prevailed, the Sheikh Semissi (q.v.) became a power, and to the Mahdi succeeded the Khalifa. But, after the English re-organisation of Egypt, in 1896 an Anglo-Egyptian army forced its way to Dongola; and in 1898 Kitchener (q.v.) completed the reconquest of the Sudan by totally defeating the Khalifa's forces at Omdurman and occupying Khartum. The discovery that Kodok (then called Fashoda) had been occupied by Major Marchand with a French force caused strained relations between Britain and France; but the question was amicably settled by the departure of Marchand in November 1898. Lord Kitchener as Sirdar was in January 1899 appointed Governor-general of the Sudan, and was succeeded by Sir Reginald Wingate, under whose administration (1899-1916) the prosperity of the country grew rapidly. During the Great War Ali Dinar, a Dar-Fâr chieftain, led a revolt (1915-16), but was overcome. Risings due to Egyptian influences and directed against the British administration took place in 1924 at Omdurman, Khartum, Port Sudan, Atbara, and other places. The disaffection culminated in the assassination of the Governor-general and Sirdar, Sir Lee Stack, in the streets of Cairo in November 1924. Disciplinary measures were at once adopted by the British government, the purely Egyptian troops being removed from the Sudan, and a Sudanese Defence Force created in their stead. Sir Geoffrey Archer became Governor-general in January 1925.

Sudbury, a municipal borough (till 1843 also parliamentary) of Suffolk, on the Stour at the Essex boundary, 16 miles S. of Bury St Edmunds. It has three old churches, mainly Perpendicular in style, a town-hall (1828), grammar-school (1491);

rebuilt 1857), corn exchange (1841), and manufactures of coconut matting, silk, and bricks. The famous woollen industry of the Flemings has died out. Gainsborough was a native. Pop. (1851) 6043; (1901) 7109; (1921) 7046.

Sudbury, a village of Ontario (pop. 8600), 60 miles N.W. of Lake Nipissing, with extensive and very rich nickel deposits. See NICKEL.

Sudd, or **SADD**, the floating masses of water weeds which, consolidating into large blocks (sometimes a mile long and 20 feet thick), obstruct the navigation of the White Nile and other African rivers. It consists mainly of *Cyperus Papyrus*, *Hemisternum diaphroxyton*, water-lilies, water-nuts, pond-weeds, and rushes.

Sudermann, HERMANN, poet and novelist, was born 30th September 1857 at Matzleben in East Prussia, studied at Königsberg and Berlin, and while acting as domestic tutor, and as editor of a small newspaper, produced tales, tragedies, and poems that were unheeded. But the drama *Ehre*, on somewhat realistic lines, was produced in 1888, and made him famous; and his novels, *Frau Sorge* (1888; Eng. trans. *Home Care*, 1892), *Der Katzensteg* (1889; trans. *Regina*, 1898), *Im Zwicklicht*, *Iolanthes Hochzeit* (1892), *Es War* (1894), *Das hohe Lied* (1908), and *Litauische Geschichten* (1919), have been widely read. The censor forbade the representation of the tragedy *Sodoms Ende* (1890). Other dramas were *Heimat* (1893), *Die Schmetterlingsschlacht* (1896), *Das Glück am Winkel* (1896), *Moriturus* (1897), *Stein unter Steinen* (1905), *Strandkinder* (1909), *Der Bettler von Syrakus* (1911), *Die Lobgesänge des Claudian* (1914), *Die entgottete Welt* (1919), *Die Raschloffs* (1920). See (for his early years) *Das Bilderbuch meiner Jugend* (trans. W. Harding, *The Book of my Youth*, 1924).

Sudetic Mountains, in S.E. Germany, divide Prussian Silesia and Lusatia from Bohemia and Moravia, and through the Erzgebirge connect the Carpathians with the chains branching from the Fichtelgebirge. They do not form a continuous chain except in the middle, in the Riesengebirge (q.v.) and Isergebirge.

Sudorifics, or **DIAPHORETICS**, remedies to excite the secretions of the skin. The simplest of all diaphoretics are baths, which may be warm baths of water or of vapour, either simple or medicated (see BATHS). The most powerful of all, however, as regards inducing perspiration is probably the Turkish bath, which consists essentially in the use of a sweating process by means of air heated to a temperature of 140° F., or even more. The following remedies, used internally, are powerful diaphoretics: antimony, ipecacuanha, opium (these three either singly or in combination); nitrites; the acetate of ammonia (spirit of milderer), phenacetin and other coal-tar derivatives; and, most active of all, pilocarpine, the chief active principle of jaborandi. On most of these substances special articles will be found. A favourite formula is Dover's Powder (q.v.), consisting of a grain of opium, and a grain of ipecacuanha in each ten grains of the powder. This in doses of from five to eight grains, followed by warm drinks and plenty of blankets in bed, usually produces copious perspiration, and is very soothing and useful in many commencing inflammatory and febrile complaints. James's powder (antimonial), in doses of from three to five grains, is often added to the above in domestic prescriptions; but neither of these medicines should be used rashly, as in certain states of the system they may prove dangerous; and they should never be given to very young children.

Sûdra. See CASTE.

Sudreys, or **SUDOREYS**. See MAN (ISLE OF).

Sue, MARIE-JOSEPH-EUGÈNE, a master of melodramatic fiction, was born at Paris, 10th December 1804. The son of an army surgeon, he himself served as such in Spain and at Navarino, and worked up his experiences into the Byronic and absurd novels, *Kernock le Pirate*, *La Salamandre*, &c., as well as the unhistorical *Histoire de la Marine Française* (5 vols. 1835-37) and *Histoire de la Marine Militaire chez tous les Peuples* (1841). In 1829 his father died leaving him a handsome fortune, which enabled him to give himself seriously to literature. His first hit was the too famous *Mystères de Paris* (10 vols. 1842), which first appeared in the columns of the *Journal des Débats*. Its successor, *Le Juif Errant*, which appeared in the *Constitutionnel* (10 vols. 1845), was no less successful. Later works were *Martin, l'Enfant Trouvé* (12 vols. 1846), *Les Sept-Péchés Capitaux* (16 vols. 1847-49), and *Les Mystères du Peuple* (16 vols. 1849), the last condemned by the law-courts of Paris as immoral and seditious. Sue was elected deputy for Seine in 1850, and attached himself to the Extreme Left. The *coup d'état* of December 1851 drove him into exile. He lived at Annecy in Savoy, and there died 3d August 1859. Sue possesses undeniably the power of holding a reader fast in his story; but his novels are hardly to be taken seriously as works of art.

Suess, EDUARD (1831-1914), the founder of the 'new geology,' was born in London, educated at Prague and Vienna, in 1857-1901 was professor of Geology at Vienna, sat for more than twenty years in the Austrian Lower House, and in 1897 became president of the Imperial Academy of Sciences. His greatest work, *The Face of the Earth* (1885-1909; trans. 1904-24), is but one of those that explain his views of the formation of continents and mountain-ranges, the dynamics of earthquakes and volcanoes, and the constitution and movements of the earth's crust. See *Nature*, May 1905.

Suet is a variety of solid fatty tissue, which accumulates in considerable quantity about the kidneys and the omentum of several domestic animals, especially the ox and sheep. Beef suet is extensively used in cookery, while purified mutton suet under the name of *Sevum Præparatum* occurs in the Pharmacopœia, and is obtained by melting and straining the internal abdominal fat. It consists of a mixture of the ordinary animal fats, with a great preponderance of the most solid of them—viz. stearin, which constitutes about three-fourths of the whole. The pure suet of the Pharmacopœia is 'white, soft, smooth, almost scentless; and is fusible at 103° (39.4° C.).' It is used as an ingredient in plasters and ointments. Ordinary melted suet is frequently employed in the same manner as lard, to preserve potted meats, fish, &c., from the action of the air. See **FATS**.

Suetonius. CAIUS SUTONIUS TRANQUILLUS, grammarian, critic, and chronicler, was contemporary with Domitian, Trajan, and Hadrian, having been born (birthplace and parentage unknown) under Vespasian. Of his manhood we find some traces in the letters of the younger Pliny, who, when appointed by Trajan proconsul of Bithynia, took Suetonius with him. Pliny's friendship, manifested in bringing him under the emperor's notice as 'probitissimum, honestissimum, eruditissimum virum,' procured him means and leisure enough for literature, of which he was a professed votary. After Pliny's death he was befriended by C. Septicius Clarus, prefect of the prætorians, to whom he dedicated his best-known work, in eight books, *The Lives of the First Twelve Cæsars*. He became Hadrian's private secretary, a post he long held till, compromised in a court intrigue, he forfeited it, to devote himself entirely to literature. He was then

about fifty years of age, but no further incident of his life is known to us.

In the compilation of his *Lives* Suetonius must have had before him the Annals and Histories of Tacitus; perhaps (according to some scholars) the *Lives* of Plutarch. But he has neither the dramatic power of the Roman nor the philosophy of the Greek. The Augustan historian Vopiscus praises him as a 'most finished and impartial writer' (*emendatissimus et candidissimus scriptor*)—merits which later criticism still allows him. His method, indeed, is of the simplest. After detailing the emperor's family history, he describes his youth and manhood till he assumes the purple; after this he abandons the chronological order and dwells on the character of his subject, as shown in public and private, according to virtues and vices, irrespective of periods of life; next he reverts to the order of time in relating the portents of death, the mode of death itself, and the terms of the emperor's will. Ever anxious to exclude uncertainty from his narrative, he deals with ascertained fact and does nothing by interposed discussion to bias the reader's judgment one way or another. With no affectation of epigram, his brevity is masterly, and probably no writer ever compressed so much that is interesting into so brief a space. He had many imitators (St Jerome among them) in antiquity and in the middle ages. His other works, *De Illustribus Grammaticis* (of which a complete copy existed in the 15th century) and *De Claris Rhetoribus*, need only be mentioned here, as also the fragmentary lives of Terence, Horace, Persius, Lucan, Juvenal, and Pliny.

After the *editio princeps* (Rome, 1470), those of Casaubon (1596 and 1610), F. A. Wolf (1802), Roth, with admirable prolegomena (1857), and Reifferscheid (1860), may be mentioned; and among translations those of Philemon Holland (1606; ed. J. H. Freese, 1923), and of J. C. Rolfe (with text, 1914).—For Suetonius Paulinus, the Roman governor of Britain, see **BOADICEA**.

Suevi. See **SWABIA**.

Suez, a town of Egypt, is situated at the southern extremity of the Suez Canal and on the Gulf of Suez, a northern arm of the Red Sea. Close beside the town the Peninsular and Oriental Steamship Company have extensive storerooms and magazines; there is a large English hospital; and the sweet-water canal from Ismailia terminates here. The railway from Ismailia runs through the town on to the spacious harbour 2 miles beyond. Suez has not a very large trade of its own; most of the commerce passes through it without making halt. Pop. (1917) 30,996. The town is surrounded by the desert. At more than one period in the past this place was the seat of a flourishing trade, as for instance in the time of the Ptolemies, when it was called Arsinoë; under the first Moslem rulers of Egypt, who called it Kolzum, the Greek name being then Clysmia; and from the 16th to the 18th century, when it formed an important *étape* in the European trade with India; but by the beginning of the 19th century it was again quite decayed. It began to revive when the overland mail route between England and India was opened in 1837, and has improved yet more since the completion of the canal. For the Suez Canal, see **CANAL**.

Suffioni, name given to the exhalations of hot sulphurous vapours, which are common in volcanic regions. See **VOLCANO**.

Suffocation. See **ASPHYXIA**, **RESPIRATION**, **STRANGULATION**.

Suffolk, the easternmost county of England, is bounded on the N. by Norfolk, E. by the German Ocean, S. by Essex, and W. by Cambridgeshire. In length from east to west it measures 57 miles,

and the mean breadth from north to south is about 30 miles. Area, 1475 sq. m.; pop. (1801) 210,431; (1831) 296,317; (1861) 337,070; (1911) 394,060; (1921) 400,058, whereof 291,073 were in the administrative county of East Suffolk, 108,985 in West Suffolk. Though no hills of any notable character rise within its confines, Suffolk is not by any means flat. Bordering on the seacoast, it is low and skirted by banks of shingle, except near Lowestoft and Southwold, and again at Dunwich and Felixstowe, which all rest on sandstone cliffs; adjoining and running parallel with these last stretches an almost continuous series of light sandy heath-lands, glorious in summer with gorse and heather; and inland the country is undulating, well-watered, and for the most part well wooded, the scenery in places—e.g. at Yoxford, aptly called the garden of Suffolk, and in the vale of the Gipping—being very picturesque. More than two-thirds of the county consists of heavy land, a stiff clay prevailing in Mid (or as it is locally termed 'High') Suffolk, whilst the western part lies upon chalk, terminating at its north-west corner with a tract of peaty fen-land. The Waveney, Alde, Deben, Orwell, and Stour, all flowing eastwards, are the principal rivers. Many of the rivers are navigable for a considerable part of their course. The Suffolk Crag, or white crag, is one of the divisions of the British Pliocene System (q.v.); and the Coprolites (q.v.) are got in the region between Ipswich and Woodbridge, gun-flints wrought at Brandon. Agriculture forms the staple industry. The soil is not rich and is very varied, so that agriculture in Suffolk is a matter of great skill. Extensive afforestation schemes are in progress in some parts where the land is useless for agriculture. A red polled breed of cattle, of which the cows are deservedly held in high esteem, is peculiar to the county; and its pigs, some black and others white, are also widely known. Horse-breeding too, apart from the racing establishments at Newmarket, is a specialty, a large export trade being carried on in both riding and cart horses; and immense quantities of lambs—blackfaced, and a cross between the Norfolk-horned and the South-down—are raised. The chief products are cement, whitening, bricks, lime, gun-flints, corn, malt, flax. Herring and mackerel fishing is important on the coast. The manufactures are noticed under Ipswich (the capital), Beccles, Stowmarket, and Sudbury, these being with Bury St Edmunds, Lowestoft, and Woodbridge, the most important towns. Formerly divided between the dioceses of Norwich and Ely, Suffolk was made a bishopric in 1913, with its cathedral at Bury St Edmunds. Its parliamentary divisions are five, each returning one member, and it has two county councils for the administrative counties of East and West Suffolk. The assizes are held alternately at Ipswich and Bury St Edmunds.

The history of Suffolk, presumably from its lying somewhat off the beaten track, presents but few facts deserving of special mention; prior to the Conquest it was in common with the rest of East Anglia (of which it formed part) oftentimes overrun and pillaged by the Norsemen, whilst of incidents of later date it will suffice to mention the descent of Flemish mercenaries under the Earl of Leicester in 1173 in support of the claims of Henry II.'s eldest son, culminating in their defeat at Fornham, near Bury St Edmunds; and the sea-fights off Lowestoft (1665) and Southwold (1671). In antiquities the county is especially rich, and amongst them may be noted the ruins of the castles of Burgh (Roman), Framlingham, Orford, and Wingfield (the last the place of Charles d'Orléans' imprisonment); the gatehouse of Butley Priory (Norman); earthworks at Fornham,

Haughley, Nacton, and Snape; the fine flint-work churches scattered throughout the county, of which perhaps the best examples are those of Blythburgh, Lavenham, Melford, Southwold, Stoke-by-Nayland, and Walberswick; and the old halls (many of them moated) of Helmingham, Parham, Hengrave, Rushbrooke, Ickworth, Somerleyton, Giffords, and West Stow. Of Suffolk worthies (exclusive of those named under Ipswich and Bury St Edmunds) the best known are Bishops Grosseteste, Aungerville, and Bale; Archbishop Sancroft; Chief-justices Glanville and Cavendish; George Cavendish (Wolsey's biographer); Lydgate, Nashe, Crabbe, and Robert Bloomfield (poets); Sir Simonds D'Ewes; the Earl of Arlington, Roger North, Capell (the Shakespeare commentator); Gainsborough, Frost, Constable, and Bright (artists); Bunbury (the caricaturist), Edwards (the etcher), Woolner (the sculptor), Lord Chancellor Thurlow, Arthur Young, Clara Reeve, Mrs Inchbald, Kirby (the naturalist), John Hookham Frere, Crabbe Robinson, Sir Philip Broke, William Johnson Fox, Professor John Austin and his brother Charles, Admirals Fitzroy and Rous, Dr Routh, Professors Maurice and Cowell, Edward Fitzgerald, Sir J. D. Hooker, Sir Henry Thompson, Agnes Strickland, and Miss Betham Edwards.

Suffragan, in England a coadjutor who assists a bishop in the administration of some part of his see: such bishops cannot succeed to the see in which they have been suffragans. The name also, and originally, belongs to all bishops in a province, in relation to the metropolitan.

Suffrage. See PARLIAMENT, REFORM.

Suffren. Pierre André de Suffren Saint-Tropes, a French naval hero, was born a younger son of a good Provence family, July 17, 1729. At fourteen he entered the navy, and first saw fire in the indecisive action with the English off Toulon in 1744. He took part in the unsuccessful attempt to recapture Cape Breton (1746), was captured by Hawke in the Bay of Biscay the next year, but soon exchanged, and after the peace went to Malta and served for six years amongst the Knights Hospitallers. Again in the French service, he took part in the action off Minorca (May 1756), was again captured in Boscawen's destruction of the Toulon fleet (1759), after the peace of 1763 cruised in the Mediterranean for the protection of trade, and took part in the bombardment of Salée in 1765. Commander in 1767, he served four years in the service of Malta, and returned to France to the rank of captain in 1772. Early in 1777 he sailed to America, and his ship began the indecisive battle of Grenada on 6th July 1779. He next served with the allied fleet blockading Gibraltar, and early in 1781 was placed in command of a squadron of five ships for service in the East Indies. After an action at the Cape Verd Islands, he outsailed Commodore Johnstone to the Cape, and so saved the colony for the time. Sailing to Madras, he fought a hard but indecisive battle off Sadras, and soon after, in a bloody two days' battle off Providien on the coast of Ceylon, proved himself a consummate master of naval tactics. But he had to struggle against scurvy, want of supplies, and, still worse, the disaffection and cowardice of his

senior officers. Having captured Trincomalee, he two days later stood out of the harbour with fifteen ships against the English twelve, and fought a hard but irregular battle. His last fight (June 1783) was also indecisive. Suffren arrived in Paris early in 1784, and was received with the greatest honours, and created vice-admiral of France. He died suddenly at Paris, 8th December 1788, most probably of apoplexy, to which his extreme corpulence made him subject. Frenchmen give the Bailli de Suffren (he had been made Bailli of the Order of Malta) the most exaggerated praises, and Sir J. K. Laughton styles him 'one of the most dangerous enemies the English fleets have ever met, and without exception the most illustrious officer that has ever held command in the French navy.' See Laughton's *Studies in Naval History* (1887), and Austin Dobson in the *National Review* for June 1912.

Sufism, a form of mysticism within Islam. The Koran is unfavourable to mysticism, for it tells of a God perfectly distinct from the world and from the souls of men, who has decreed from all eternity the lot of every person, and who is to be pleased with outward rites and conduct. Sufic mysticism has come into Islam through Persia, where, under the influence of Indian Buddhism, its pantheistic ideas existed before the Mohammedan conquest. Sûfis claim as their founder the woman Râbia, whose grave on a hill east from Jerusalem drew many pilgrims in the middle ages. But that distinction rather belongs to Abû Saïd Ibn Abî-l-Çhair, a Persian of Khorasan, who, notwithstanding the saying of Mohammed that there is no monkery in Islam, founded a monastery about 815. His followers were called Sûfis or Woollers from their ascetic garb. A contemplative life soon naturally sought in Pantheism that rest for the heart which it could not find in the distant, unsympathetic God of Islam. Thereafter Sufism divided itself. Some with the Persian Bestâmî, who died in 875, professed openly that man is God. Others with Jonâid, who died in 909, a Persian too, though born in Bagdad, were of like faith, but cautious and orthodox in their language. The favourite watchword of Islam, the Unity of God, meant with them that God is all. The object of all Sufism was to deliver the soul from the sway of the passions by destroying human nature and the power of the flesh, and so to make the soul merely spiritual, uniting it by love with God, from whom it had emanated as a ray emanates from the sun. Cautious Sûfis were often revered as saints, while sometimes the incautious became martyrs. Many, like Jonâid's pupil Hallâj, who was executed by Hâmid, the vizier of the khalif Al-Moqtadir at Bagdad in 922, were alternately adored and persecuted. In Sufism the devotee must choose a teacher, and strive toward development through degrees, of which there are commonly reckoned three. First is the Law, wherein the Sâfi is merely a Muslim, blameless in all ordinances of morality and of Islam; but the only motive to worship or obedience is not fear of punishment nor hope of reward, but love. Second is the Way or Method, wherein he practises asceticism, fasts, watches in silence and solitude, studies Sufistic lore, drives away other thought, rises into an occasional ecstatic state, Hâl, which when permanent is called a position, Makâm. Positive religion, needful for the weak, is now needless for him. The final degree is Certainty; the transcendental objective God has now become subjective; the Sâfi is now consciously God; all religion is vain. The first great Sâfi poet was the Persian Ferîd eddîn Attâr, who died c. 1220. The greatest Sâfi poet was another Persian, Jelâl eddîn Rûmî (1207-73). But Sufism, the dream of the least and the most cultured alike,

has been the religion of Hâfiz and Sâdi and of nearly all the great Persian poets. Their luscious language of love and beauty's charms, of intoxication and the wine-house, is strongly sensual or spiritual according as it is taken. Of the Sâfides, who reigned over Persia from 1499 to 1736, the first was Ismâel the Sâfi. In 1777 a famous Sâfi, Mir Maçmû Ali Shâh, came from India to Shirâz, and raised a great Sâfi fervour, against which a very severe persecution was started by church and state in 1782, and lasted many years. Yet the influence of Sufism in Persia and eastward is rather increasing than waning; and in all orthodox lands this most fatal dissolvent of Islam is welcomed. There are many sects in Sufism. In Persia when the 19th century began there were at least a quarter of a million of Sûfis. There are more now; but with a majority the name means not pantheist but reethinker. In this sense the Sâfis or Wise may include half of the Persian middle class.

Sugar, a term applied generally to any of the members of a pretty numerous natural group of substances, for the most part of vegetable origin, connected with glycerol and the glycols on the one side and with the dextrins and with bodies of the starchy class on the other. They are, as a rule, crystallisable, soluble in water, less soluble or insoluble in alcohol, and insoluble in ether and in other solvents which are immiscible with water; they have a sweet taste. Most sugars possess the property of causing rotation of the plane of polarisation of light, and this optical activity serves as a means of estimation of very great value to the analyst. The sugars are divided according to the views entertained as to their constitution into two main classes: the *monosaccharoses* and the *disaccharoses*. The *monosaccharoses* have the general formula $C_6H_{12}O_6$. Glucose or dextrose, fructose, and mannose closely resemble one another, reduce Fehling's solution, readily ferment (except the last) with yeast, rotate the plane of polarisation, and when oxidised yield saccharic acid. Galactose closely resembles fructose, but has a feeble action on Fehling's solution, and yields mucic acid under the influence of oxidants. Some, such as sorbitose, do not ferment with yeast, but are acted upon by the lactic and butyric bacteria.

Glucose (synonymous dextrose, grape-sugar) is the most important sugar of the monosaccharose class. It occurs in the anhydrous condition as transparent prismatic crystals, and in watery masses having the composition $C_6H_{12}O_6 + H_2O$, which lose all their water below $100^\circ C$. It melts at $146^\circ C$, is less soluble in water and in alcohol than cane-sugar, and dissolves in boiling water in all proportions. Glucose has a dextro-rotatory action upon polarised light, and reduces Fehling's solution. It is not affected by moderate boiling with dilute acids, nor does it readily char under the influence of strong sulphuric acid, but forms with it an acid ethereal salt decomposed by water. It also forms analogous compounds with many other acids. It is rapidly decomposed on boiling with caustic alkalis or caustic lime. Glucose is found ready formed in the grape to the extent of 15 per cent, and in many other fruits. It may be prepared by decomposing the glucosides and by the hydrolysis of starch, dextrin, cane-sugar, &c., by means of dilute acids, diastase, or invertase, also by the action of sulphuric acid upon cellulose. In honey and in many fruits it occurs in association with fructose (or levulose), a monosaccharose which bears a great resemblance to it, but is distinguished by having a greater sweetness and a laevo-rotatory power. Fructose is said to be even sweeter than cane-sugar.

The *disaccharoses*, with the general formula $C_{12}H_{22}O_{11}$, are the most important sugars, inas-

much as ordinary sugar, malt-sugar, and sugar of milk are members of this class. They may be regarded as condensation products of the monosaccharoses, and derived from two molecules by elimination of the elements of water. The saccharoses are, with the exceptions of malt-sugar (maltose) and milk-sugar (lactose), incapable of reducing Fehling's solution. They are fermented by yeast only after previous conversion into monosaccharoses by the agency of an enzyme (or enzymes), invertase, secreted by that organism. The disaccharoses are charred by strong sulphuric acid.

Sucrose (cane-sugar) is a solid crystallising in the form of monoclinic prisms—generally with hemihedral faces—which are transparent, colourless, and have a sweet taste, a specific gravity of about 1.6, a melting-point of about 160° C. It strongly rotates the plane of polarisation to the right. Sucrose is soluble in about half its weight of cold water and in boiling water in all proportions; it is nearly insoluble in absolute alcohol and soluble in dilute alcohol, the solubility increasing with the dilution in an ascending ratio. Ether, chloroform, carbon disulphide, oil of turpentine, petroleum spirit, and liquids immiscible with water generally, have no solvent action upon this sugar. Sucrose melts at about 160° C., and assumes on cooling the condition known as 'barley-sugar.' On further heating, water is given off, and the mass begins to blacken with evolution of fumes having a characteristic odour; and at about 200° C. caramel, a mixture of caramelin, $C_{12}H_{18}O_9$, caramelen, $C_{20}H_{26}O_{13}$, and caramelin, $C_{36}H_{46}O_{23}$, is obtained. Caramel is largely used for the colouring of wines, beer, vinegar, &c. Alkaline hydroxides in the cold have little or no action on sucrose, but when fused with caustic potash this sugar yields oxalate and acetate of potassium.

Solutions of sucrose possess the property of dissolving the oxides of the alkaline earths, with which the sugar forms compounds of definite composition. The *Liquor Calcis Saccharatus* of pharmacy is a solution of lime in syrup, and with baryte, sucrose forms the compound $C_{12}H_{22}O_{11}(BaOH)_2$, which falls as a precipitate when syrup is mixed with a concentrated solution of barium hydroxide. With strontia sucrose forms the compound $C_{12}H_{22}O_{11}(SrOH)_2$ as a precipitate, and this reaction is employed commercially for the separation of crystallisable sugar from molasses. The precipitate is granular, easily separates, and after being washed with hot water is decomposed with carbonic acid.

Sucrose in the solid condition, or in the form of a strong syrup, is decomposed in the cold by concentrated sulphuric acid, with formation of a spongy carbonaceous mass, and evolution of sulphur dioxide and other volatile products. Nitric acid acts upon sucrose, forming nitrosucrose, saccharic acid, oxalic acid, or carbonic acid, according to the concentration of the nitric acid; the fuming acid in the cold produces nitrosucrose. Sucrose, like all the members of the disaccharose group, is hydrolysed when heated in solution with dilute acids; in the case of sucrose a mixture of glucose and fructose results, the change consisting in the assimilation of the elements of water and bisection of the sucrose molecule, thus:

This action is termed 'inversion,' because the solution after the action of the acid rotates the plane of polarisation to the left, but the term is now applied generally to the hydrolysis of disaccharoses by acid. Inversion takes place slowly even in the cold with hydrochloric or sulphuric acid, and with

dilute solutions of sucrose, but at 70° C. the change is very rapid; acetic, tartaric, citric, and the other weak acids have much less power in this respect. The process of inversion is of value in analysis of mixtures of various sugars.

Sucrose is a strong reducing agent, which is another way of saying that it is readily oxidised. It quickly decolorises solutions of potassium permanganate even in the cold, and on boiling with it yields oxalic and carbonic acids. When heated with solutions of silver or mercury it causes separation of the metal, and it precipitates gold from the chloride. When boiled with cupric salts in presence of alkaline hydroxides there is no separation of cuprous oxide, but after continued ebullition a partial reaction occurs. After undergoing inversion by dilute acids or invertase it quickly and completely reduces alkaline solutions of copper (see end of article).

The behaviour of sugar under the influence of living ferments is of great interest theoretically, and of importance from a practical point of view. See FERMENTATION; also ALCOHOL, BEER, YEAST.

Besides sucrose the only disaccharoses of practical importance are lactose and maltose. Lactose is the natural sugar of milk. It is a solid substance of sweetness inferior to sucrose, crystallising in hard, white, semi-transparent masses, having the composition $C_{12}H_{22}O_{11} + H_2O$, soluble in water, but insoluble in alcohol or ether. When boiled with dilute sulphuric or hydrochloric acid it is converted into the two monosaccharoses, glucose and galactose. It is not fermented by yeast alone, but in contact with yeast and putrefying casein it ferments, yielding alcohol and lactic acid. Koumiss is a product of such fermentation acting upon the milk of mares. Lactose reduces Fehling's solution and rotates the plane of polarisation to the right.

Maltose, $C_{12}H_{22}O_{11}$, occurs in fine crystalline needles, soluble in water and in alcohol, but to a less extent than sucrose. This sugar reduces Fehling's solution, and has a dextro-rotatory polarisation. It derives its chief interest and importance from the fact that it is the principal ingredient in beer worts, in which it owes its presence to the action of an enzyme, diastase, possessing the power of hydrolysing starch, and forming from it maltose and dextrin, but not glucose, as was formerly supposed. It is probably not directly fermentable by yeast, but is rapidly inverted by that organism and converted into alcohol and carbonic acid.

Sources of Sucrose.—Sucrose occurs very widely in the vegetable kingdom. It is found in the sugar-cane (*Saccharum officinarum*), of which a number of varieties are known and cultivated; in many other grasses; in the sap of many forest trees; in certain roots; in numerous seeds; in most sweet fruits, usually in association with invert sugar; and in the nectar of flowers. The sugar-cane was the source from which sugar was originally prepared, and the East first learned its use. The early classical writers, especially Herodotus, Theophrastus, Seneca, and Strabo, make undoubted references to sugar, which they speak of as 'honey of canes,' or 'honey made by human hands'; and at about the date of the Christian era it had become pretty generally known under the name of *sakcharon* or *saccharum*. The term candy, applied to sugar in large crystals, took its origin from the Arabic and Persian *kand* or *kandat*. It is believed that Bengal was the region in which cane-sugar in a dry granular state was first prepared. The Chinese admit that they first gained their knowledge of sugar-making from India, somewhere about 766 to 780 B.C. We have evidence that in the 9th century of our era, sugar was grown in Persia, and the Persian physicians of the 10th

and 11th centuries first introduced it into medicine. The Arabs cultivated the cane in many of their Mediterranean settlements, and as early as 961 A.D. the plant flourished in the Iberian peninsula. Soon afterwards sugar of Egyptian origin formed a staple of trade between the merchants of Venice and of London, wool, which then constituted the great wealth of England, being largely exported in exchange for it.

The sugar-cane has been introduced into almost all tropical and subtropical countries; the East and West Indies, the southern United States, Central America, Brazil, Peru, Chile,

Sugar-cane (*Saccharum officinarum*).

Mauritius, the Malayan Archipelago, Egypt, northern Australia, South Africa, and many islands of the Pacific may be mentioned as illustrating the wideness of its range, although the list is by no means exhaustive. The cane seems to have been introduced by Jesuits into the southern United States from the West Indies about 1750; but sugar culture was neither an important nor prosperous industry when Louisiana was ceded to the United States in 1803. This state soon became and still is a great sugar-producing state; the cane is grown in all the Gulf states on both sides of the Mississippi (though in all these states it sometimes suffers from frost). In Europe it is or has been grown a little in Sicily and in Andalusia.

The cane, which may be described as a gigantic grass, thrives best in a warm, moist climate, with prevalent sea-breezes and moderate intervals of hot, dry weather. Many descriptions of cane exist, and these are regarded as varieties of one species, although some botanists have raised a few to the rank of distinct species. The stem, which varies from 6 to 14 feet in height, is from 1 to 1½ inch thick, and jointed at intervals of from 3 to 6 inches; its pith, of open cellular structure, contains the sugary juice. The tops and lower joints are not crushed; the outer skin contains much silica. The 'arrow' or flowering stem is without joints, and bears a panicle of soft, silky flowers. The

cane suffers much from the ravages of rats (to check which the mongoose or ichneumon has in some places been successfully used), from white ants, and several boring insects. It is propagated from the eyes or buds which grow on the stems, as it generally fails to ripen its seed; and the 'stoies,' or portions remaining in the ground, throw up fresh canes, called ratoons, for several seasons—sometimes twenty years—after which replanting is necessary. The young cuttings are planted in rows 3 feet apart, and at intervals of 2 feet from plant to plant. Seedlings have been known since 1888, and are used to improve the race. The cane requires a fertile, marly soil, not too heavily charged with common salt or other saline ingredients. The most suitable manure is farmyard dung or night-soil; superphosphates and the various artificial fertilisers are considered to be less advantageous, but the presence of lime is of primary importance. Potash is useful.

The beet-sugar industry was first stimulated by Napoleon I., especially during the period when France was deprived of sugar by the English blockade, and has assumed immense proportions owing in great measure to the scientific skill that has been expended upon it. The Beet (q.v., *Beta vulgaris*) is indigenous to Europe, and many varieties of this plant, as of the sugar cane, are known. The juice of the root contains from 12 to 18 per cent. of crystallisable sugar associated with various salts, such as the phosphates, oxalates, malates, and chlorides of potassium, sodium, and calcium, besides albuminous, pectinous, and other substances. The plant thrives best in a deep, friable 'turnip loam,' neither too stiff nor too light, and manuring with phosphatic manures gives the best results; peaty and moorland soils and farmyard manure are less suitable. The seed is usually sown in April, and the crop gathered in autumn before the incidence of early frosts.

Sucrose is also made in America from the sugar-maple (*Acer saccharinum*) and the melon (*Cucumis Melo*); in America and elsewhere from different varieties of sorghum (see *GUARA*) and from maize (*Zea Mays*); and in various tropical countries from many species of palm.

Manufacture.—While differing in details, the extraction of sugar from cane and beet is on the whole the same in its main outlines. The cane is crushed to express the juice. Sometimes before the final crushing it is macerated in water. Beet-root is cut in slices and the sugar extracted by diffusion, for it will pass through an unbroken cell-membrane (see *OSMOSIS*). The same can be done with short lengths of sugu cane, and on the other hand pressing and maceration have been used in the past with beet. So long as the juice remains within the plant-cells it does not ferment, but when it is liberated fermentation soon begins. Therefore without loss of time the juice or solution is heated with milk of lime to neutralise acids and coagulate proteins. Excess of lime is precipitated by carbon dioxide. The liquid is decolourised with animal charcoal, and filtered. Then follows evaporation in a vacuum pan heated with steam. Crystals form in the concentrated syrup, and are separated from it by a centrifugal machine and purified by recrystallisation from water. The molasses still contains much sucrose which refuses to crystallise; most of which can be got by adding strontium hydroxide, as has already been explained. The strontium carbonate being removed, the filtrate is evaporated to a syrup, and sucrose crystallises out.

Palm-sugar is derived from the juice which flows from incisions made in the trunk of the tree. This is very pure, containing less non-saccharine matter than cane-juice, and far less than beet-juice, and the sugar is obtained by simple evaporation in

open pans. Sorghum-sugar is extracted and fabricated by processes that are almost identical with those employed in making sugar from the cane, but the machinery is usually constructed on a much smaller scale. Maple-sugar is manufactured by simple evaporation in iron or copper pans of the sweet sap draining from anger holes made in the trunk during spring.

In former years, before the beet industry assumed its present enormous proportions, and when the cane was the chief source of supply, sugar was to a great extent consumed in the condition in which it arrived from the producing country. This, which was possible and even pleasant with the sweet and fragrant cane muscovadoes, became impossible when raw beet-sugar with its unpleasant vegetable flavours was introduced, and the practice of refining all sugars became established. The hogsheds of muscovado, bags of beet, mats of jaggery (as most of the sugar from the East is called), or other packages, are discharged, the sugars mixed, and dissolved in hot water to a syrup. The syrup flows through filter-bags, of which a large number are required, owing to the slimy nature of the suspended matter, and is then caused to gravitate down large iron cylinders packed with granulated animal charcoal, which can be 'revived' many times (see CHARCOAL). The first syrup running from the char-cisterns is quite colourless, and is collected apart and boiled for the production of crystals (loaf-sugar being almost obsolete). The last portions of syrup yield the 'pieces' or yellow moist sugar. The boiling is effected in vacuum-pans, and a small quantity of sulphurous acid is added to the pan and greatly improves the colour of the 'pieces.' In boiling this class of goods the object is to form a 'false grain'—i.e. an aggregation of small grains having the appearance of larger particles; in this way a soft-looking sugar of primrose complexion and carrying a large quantity of syrup, which pleases the eye much more than a gray-looking 'piece' sugar of bolder grain, is obtained. The thick mass from the pan is discharged through an opening in the bottom into centrifugal machines, which, with the aid of a little wash water, separate the crystals from the syrup. This operation of 'machining,' it should be mentioned, is frequently applied to hard grainy beet-sugars in the initial stage of refining, and the resulting ill-smelling impure syrup treated apart from the grayish white and comparatively pure crystals left upon the machine.

Lump sugar is made by draining a very stiff masse-cuite of small grain in moulds, and afterwards drying the concentered loaves; for the production of cube sugar moulds of peculiar shape are used, which when filled are placed in centrifugal machines to facilitate the removal of the syrup. The slabs are then cut by machinery into cubes.

Analysis.—Three estimations are chiefly necessary for the analysis of raw sugar, the determination of polarising value, of glucose, and of ash or mineral matter. The polarimeter is an instrument by which the rotatory power of sucrose (or other sugars) upon a ray of polarised light is made available for purposes of quantitative measurement. Those instruments are the best that require the use of the yellow light of the sodium ray. The two Nicol's prisms of the polarimeter being crossed and the vernier at zero, a filtered solution of sugar containing a known weight of the sample in unit volume is introduced into a tube 20 centimetres long and placed between the prisms. The result is a transmission of light requiring for its suppression the rotation of the analysing prism, the one nearest to the eye. From the angular degrees of this rotation the polarising value of the sample is deduced.

In actual instruments an ingenious device is made use of for the sake of gaining delicacy. This consists in covering one-half of the optical field with a half-wave plate of quartz or of mica; the field in these instruments is always more or less bright, but the slightest movement of the prism in either direction from the neutral point causes an unequal shadowing of the two half-disks, and very sharp observations can be made. The presence of glucose in sugar, and the amount, are ascertained by titration with standard Fehling's solution made by dissolving in every litre 34.64 grams of crys. sulphate of copper, 70 grams of caustic soda, and 180 grams of Rochelle salt. This liquid is not affected by sucrose, but when a solution of a sample containing glucose (also maltose, lactose, &c.) is delivered into a known volume of the copper solution diluted with water, and kept at the temperature of boiling, the copper is precipitated as red suboxide, and the supernatant liquid becomes colourless. The volume of the solution of sugar required to effect this result is a measure of the glucose present. The ash of sugar is ascertained by burning 1 gram of the sample in a platinum capsule at a red heat; but, owing to the difficulty of obtaining a white ash from the fusible salts, it is usual in technical practice to add two or three drops of strong sulphuric acid before ignition, and to deduct one-tenth for the extra weight thus introduced.

Sugar of Lead. See LEAD, p. 564.

Suggestion. See HYPNOTISM.

Suhl, a town of Prussia, standing in a romantic valley on the south-west side of the Thuringian Forest, 32 miles by rail S.W. of Erfurt. It has long been celebrated for its manufacture of firearms, both military and sporting, and from the middle ages down to the 18th century was no less celebrated for its swords and war-armour. There are also iron and machine works, potteries, and tanneries. Pop. 15,000.

Suhm, PETER FREDERIK (1728-98), a Danish historian, was born and died at Copenhagen.

Suicide (a word coined in England on a French model, but of Latin elements), according to English law, is a Felony (q.v.). A person found *felo de se* (guilty of self-murder) by a coroner's jury was formerly buried at a cross-road with a stake driven through his body, but this barbarous practice (a survival probably of the vampire superstition) was abolished in 1823. A person is *felo de se* if he commits any felonious act which results in his own death; a person who shoots at another with a gun which bursts and kills himself, a woman who dies of poison taken to procure miscarriage are both guilty of self-murder. If two agree to assist one another in committing suicide, and one survives, he is guilty of murder. Policies of life insurance are usually so framed as to be void if the insured dies by his own act, whether he is of sound mind or not. In Scotland suicide involves 'single escheat' or forfeiture of the movable estate of the deceased to the crown; but this rule is never in ordinary cases put into force. In the United States the constitutions of several states provide that the property of suicides is not to be forfeited.

The question of the moral justification of suicide has exercised the minds of ethical philosophers from the days of Plato, Marcus Aurelius, and Seneca down to the present time. Some schools of thought, notably Stoics and their adversaries the Epicureans, defended suicide under proper conditions; Christianity has always refused to admit any justification for self-destruction, and the Roman and Anglican churches deprive of ecclesiastical burial those who have without doubt wilfully committed self-murder.

From the medical point of view suicide is in the majority of cases a symptom of disease of the brain. It is not now denied, however, by any competent medical authority that sane men may and do commit suicide. The brain constitution of some persons is such that when they are under the immediate influence of alcohol they always become suicidal. The next kind of case in which suicide is attempted is one on the borderland of disease. It is the man intellectually sound and not emotionally depressed who simply loses for the time his normal love of life, ceases to have any fear of death, suffers from the *tedium vite* of the ancients, and for trivial causes or for no outward cause at all, attempts his life. Some such men are in Hamlet's frame of mind: 'To be or not to be? That is the question.' A man in this state, which is often a hereditary one, cannot always be reckoned insane, and yet he is in an abnormal state of brain and mind. The mass of suicides are committed or attempted by persons either insane or on the verge of insanity. The two forms of insanity in which suicidal impulses are most frequent are melancholia and alcoholic insanity. Four-fifths of all patients suffering from melancholia have suicidal feelings, and two-fifths of them make actual attempts on their lives. It is a risk that should be considered and provided against in every case of melancholia and in every case beginning to suffer from alcoholism or alcoholic insanity. The tendency to suicide is very hereditary. Suicide may be carefully contrived and planned for months, or it may be done through a momentary morbid impulse. It may be done, and commonly is done, from insane delusions, such as that the patient is going to be killed and tortured, that he is going to be tied, that his food is poisoned, that he is too great a sinner to live and must make expiation, that he is the cause of evil to all around him, that he cannot recover, &c. Physicians especially guard against suicide with patients who are very much afraid they are to be put to death, and who therefore might be supposed to be too much afraid of dying to do any harm to themselves. Prolonged sleeplessness will sometimes lead to suicidal feelings through brain exhaustion. Suicidal feelings are sometimes the very first symptom of insanity, before anything mentally wrong is suspected and before any watching or precautions are therefore taken. Attempts at suicide are sometimes made while the patient is quite unconscious or in a state of altered consciousness, so that there is no recollection of it afterwards. Sometimes it is suggested by the sight of a weapon or water or any such means of destroying life. When the suicidal desire is strongly present it is a mistake to suppose that the patient's former religious sentiments, or his sense of duty, or his obligations to those dependent on him, or any other rational motive can be depended upon to prevent his committing the act.

The modes of committing suicide vary in different countries, in the two sexes, and in different professions. Suicide is much more common among men than among women, being in the proportion of 3 or 4 to 1; and this applies to all countries and races. As to age, 'suicide augments in the two sexes in direct ratio with age,' at least up to the seventieth year; there are instances of suicide at five years of age, and also over ninety. The critical periods of life, adolescence, the climacteric, pregnancy, parturition, nursing, and senility all increase the tendency to suicide, just as they increase the tendency to insanity. Suicide in all civilised countries is becoming more common year by year. Physical diseases, notably those that are very painful and those that are slow and chronic, increase the

number, as does increased consumption of alcohol, especially spirits. The religion of a people seems to exercise a marked influence on the number of suicides. There are more in Protestant than in Roman Catholic countries. But the social circumstances of each country need to be taken into consideration. Suicide is most common among the widowed and least frequent among the married. The military profession furnishes much the largest proportion. It is commoner among town-dwellers than in the country.

See the articles INSANITY, EUTHANASIA, HARA-KIRI, and SUTTEE. The suicide of Scorpions (q.v.) and snakes, often asserted, has been proved to be impossible.

Suidæ, a family of even-toed, non-ruminant Ungulates, including pigs, hogs, or boars, the Babiroussa, and the wart-hogs (*Phacocheirus*). The snout is mobile but truncated; the feet have four toes, of which two reach the ground; the upper canine teeth curve more or less outwards or upwards; the molars bear rounded tubercles; the stomach is almost simple. In distribution they are entirely confined to the Old World, the American pigs or peccaries belonging to the family *Dicotylidæ*.

Suidas, the reputed author of a *Lexicon*, though when he lived, or who he was, or whether he was even called Suidas, no one can say; but it is customary to place him about the 10th or 11th century. The *Lexicon* bears unmistakable evidence of having gone through many hands; and though we can fix the date when several of the articles *must* have been written, it is impossible to ascertain whether they are the composition of the first compiler or of a later editor. The work is a sort of cyclopædia, giving an explanation of words, and notices of persons, places, &c., in alphabetical order. It possesses almost no literary or critical merit, but is valuable for its numerous extracts from ancient writers, whose works in many cases have perished. The first edition appeared at Milan (1499); since then the best editions have been those of Kuster (3 vols. 1705), Gaisford (3 vols. Oxf. 1834), Bernhardy (2 vols. Halle, 1834), and I. Bekker (1854).

Sui Juris, in Roman law, the condition of a person not subject to the *Patria Potestas*. The *paterfamilias* was the only member of a family who was *sui juris*, all the rest being *alieni juris*, including sons, unmarried daughters, the wife, and the wives and children of the sons of the *paterfamilias*. A son or unmarried daughter became *sui juris* on the death of the *paterfamilias*. In his father's lifetime a son could only become *sui juris* by emancipation.

Suir, a river of Ireland, flowing 85 miles southward and eastward, chiefly along the boundary of the counties of Tipperary, Waterford, Kilkenny, and Wexford, past Clonmel, Carrick, and Waterford, till it meets the Barrow, and immediately afterwards falls into Waterford Haven. It is navigable by barges as far as Clonmel.

Suite, a series of dances arranged for instruments in the same or relative keys, and usually preceded by a prelude.

Sukhum Kale, a fortified seaport town of the Caucasus, on the east coast of the Black Sea, 70 miles N. by W. of Poti. It stands on the site of the ancient Milesian colony of Dioscurias, and since 1809 has been alternately in the hands of the Turks and the Russians; the latter held it from 1877. It is now capital of Abkhasia, within the republic of Georgia.

Sukkur, a town on the right bank of the Indus, 28 miles by rail S.E. of Shikarpur; it is connected by rail also with Karachi (Kurrachee), and is the terminus of the Bolan Pass Railway to Afghanistan. The river is crossed by a magnificent

cantilever bridge (1889), or rather by two bridges (one with a span of 820 feet), resting upon the fortified island of Bukkur in the middle of the channel. New Sukkur, which grew up after the British occupied (1839) the fort on Bukkur, has considerable trade in silk, cloth, cotton, wool, opium, saltpetre, sugar, brass utensils, piece-goods, metals, wines and spirits. Pop. (1834) 4000; (1872) 13,318; (1921) 42,759. Old Sukkur, about a mile away, has a good many old tombs in its immediate vicinity. One of the largest irrigation projects ever attempted is now being executed at Sukkur. It includes the construction of a barrage across the Indus, and of new canals on each side of the river. The work is expected to occupy about 12 years and to cost over £13,000,000. The scheme when completed will enable some 3½ million acres of waste land to be added to the area under cultivation, to the great benefit of the people of Sind.

Suleiman Pasha, Turkish general, was born in Rumelia in 1838, entered the Turkish army in 1854, fought in Montenegro, Crete, and Yemen between that date and 1875, and in the intervals of peace taught in the Military Academy at Constantinople, and finally presided over it as director. He greatly distinguished himself as a corps commander against the Serbians in 1876, and was in 1877 nominated governor of Bosnia and Herzegovina. When the Russians declared war (1877) against Turkey Suleiman checked them at Stara Zagora, and destroyed his army in heroic but vain attempts to force them from the Shipka Pass. In October he was appointed commander-in-chief of the army of the Danube, but failed to accomplish anything, retreated behind the Balkans, and suffered defeat near Philippopolis (January 1878). He was condemned to be degraded and imprisoned for fifteen years. The sultan pardoned him, and he died at Bagdad 11th August 1892. Personally brave, he seems to have been a corrupt and designing traitor.

Suliman or **SULAIMAN HILLS**, a mountain-range upwards of 350 miles in length, running in a straight line from north to south, and forming the boundary between Baluchistan and the Panjab. The highest summit of the range, Takht-i-Sulaiman (Solomon's Throne), 11,295 feet high, was first ascended by a European, Major Holdich, in 1883. The general appearance of the range is rocky, precipitous, and bare of trees.

Sulina, one of the lower branches of the Danube (q.v.), in Rumania. The town of Sulina, on its south bank and near its mouth, is a great transshipping port and naval base, with 10,000 inhabitants. It was bombarded by the Russians in 1877.

Suliotcs, a tribe who inhabited the valley of the ancient Acheron, in Epirus, included in Greece since the war of 1912-13, are a mixed race, being partly of Hellenic and partly of Albanian origin. They are the descendants of a number of families who fled from their Turkish oppressors to the mountains of Suli (whence they derive their name) near Parga during the 17th century. In this corner of the Turkish empire they prospered, and towards the close of the 18th century numbered 560 families, inhabiting 90 hamlets. For several years they heroically resisted the attempts of the Turks to deprive them of their independence. But vanquished at length (1803), they retreated to the Ionian Islands, where they remained till 1820, when Ali Pasha, finding himself hard pressed by the Turks, invoked their aid. The Suliotcs, eager to return to their home, threw in their lot with him, but were ultimately forced to surrender their stronghold of Suli to the Turks, and again to flee

from their country. About 3000 of them took refuge in Cephalonia, though large numbers preferred to skulk in the neighbouring mountains. Though they took a glorious part in the war of Greek independence, their country was not included by the treaty of 1829, nor by the extension of 1881, within the Greek boundary line. Nevertheless most of them established themselves in Greece, where their leaders were raised to important offices. See Perrihaebos' *History of Suli and Parga* (1815; Eng. trans. 1823).

Sulla, **LUCIUS CORNELIUS**, surnamed by himself **FELIX**, a scion of the illustrious house of the Cornelii, was born in 138 B.C. His limited patrimony was sufficient to secure him a good education, and his youth was spent not more in the pursuit of pleasure than in the study of the Greek and Roman authors. The liberality of his step-mother increased his slender means, and enabled him to aspire to the honours of the state. As quaestor in 107 under Marius in Africa he crowned a series of important successes by inducing Bocchus, the Mauritanian king, to surrender Jugurtha, whom he brought in chains to the Roman camp (106). The war of the Cimbric and Teutonic (104-101) saw Sulla again serving under Marius, whose jealousy, however, drove him to take a command under the other consul, Quintus Catulus. In 93 he was praetor, and in 92 propraetor in Cilicia, where the senate sent him with special orders to restore Ariobarzanes to the throne of Cappadocia, from which he had been expelled by Mithridates. After achieving a complete success, Sulla returned to Italy in 91. The private hatred of Marius and Sulla began now to take on a political aspect, as the aristocratic tendencies of the latter grew prominent. Their long-smouldering animosity was on the point of bursting forth, when the breaking out of the Social War hushed all private quarrels for the time. The aged Marius had now the deep mortification of finding his military achievements thrown into the shade by the brilliant successes of his rival. The expectations of Marius were dashed to the ground when the senate bestowed on Sulla, after his consulship in 88, supreme command in the Mithridatic war. Marius rushed headlong into treason and civil strife. Then followed the expulsion of Sulla from Rome, his triumphant return at the head of his devoted legions, the overthrow of the Marian party, and the first proscription. By the beginning of 87 Sulla was able to embark for the East. During the four years he spent there he won the victories of Chéronée (86) and Orchomenus (84) against Archelaus, the general of Mithridates. Next he crossed the Hellespont, crushed Fimbria, who had obtained the command of the army sent out by the Marian party (which, in Sulla's absence, had again got the upper hand in Italy), forced Mithridates to sue for peace, then sailed for Italy and landed at Brundisium (83). The victory over the Samnites and Lucanians at the Colline Gate brought the struggle to a close (82), and Sulla was now master of Rome and Italy. Then followed his dictatorship, and the period of the proscriptions (81)—a virtual reign of terror, in which of senators were slain perhaps from one to two hundred, of knights between two and three thousand. During the next two years several very important constitutional reforms were carried, mostly reactionary, and tending to increase the authority of the senate. The restoration of the *judicia* to the senate, the abolition of the functions of the *comitia tributa*, the withdrawal from the tribunes of the right to summon the *comitia*, the doubling of the number of the senate, the annual election of twenty quaestors, the enactments that no man should be praetor without having been quaestor, or consul without having been praetor,

and that *tribuni plebis* should be eligible for no other office, the institution of *quaestiones* without appeal confined to special classes of crimes—these were some of the provisions of a legislation, with a few exceptions, doomed to fall within ten years. In 79 Sulla resigned the dictatorship and retired to his estate at Puteoli, where, surrounded by buffoons and dancers, he indulged to the last in every sensual excess of which his exhausted frame was capable. He died in 78, at the age of sixty. His monument in the Campus Martius bore an inscription, attributed to Sulla himself, which said that none of his friends ever did him a kindness, and none of his foes a wrong, without being largely requited.

See Oman's *Seven Roman Statesmen* (1902).

Sullivan, SIR ARTHUR SEYMOUR, was born in London, 13th May 1842. He studied music under Sterndale Bennett and Goss, and at Leipzig, and had his music to *The Tempest* performed at the Crystal Palace in 1862. He then produced the cantata *Kenilworth* in 1864, the overtures *In Memoriam* (1866), *Marmion* (1867), and *Di Ballo* (1869), the oratorios *The Prodigal Son* (1868) and *The Light of the World* (1873), a Festival Te Deum for the Prince of Wales's recovery in 1872, and at Leeds in 1880 and 1886 *The Martyr of Antioch* and *The Golden Legend*. To the general public, however, he is better known by his hymn tunes, his songs, and still more his tuneful and popular operas and operettas. The latter began with *Cox and Box* in 1866, and include the long list given already in the article on W. S. Gilbert (q.v.); they are notable for an orchestration full of subtle and humorous touches that render his operas of special interest to musicians. The fertility and technical resource squandered on these productions were devoted to higher work in the grand opera of *Tianhoa* (1891). He was the first principal (1876-81) of the National Training School for Music, was made Mus. Doc. of Cambridge in 1876 and of Oxford in 1879, received the Legion of Honour in 1878, and in 1883 was knighted. He died 22d November 1900, and was buried in St Paul's.

Sullivan, BARRY, tragedian, born at Birmingham in 1824, first appeared at Cork in 1840, played at Edinburgh and elsewhere, and at the Haymarket in London as Hamlet in February 1852. He visited America in 1857-60, and Australia in 1861-66. He was afterwards for a while lessee of the Holborn Theatre; but he was more popular in the provinces, especially in Ireland and the west of England. He died at Brighton, 3d May 1891.

Sully, MAXIMILIEN DE BÉTHUNE, DUC DE, the famous minister of Henry IV. of France, was the second of the four sons of François, Baron de Rosny, and was born at the château of Rosny near Mantes, 13th December 1560. At an early age he was committed to the care of Henry of Navarre, head of the Huguenot party, narrowly escaped the St Bartholomew massacre (1572), and accompanied Henry in his flight from court (1576). He took an active part in the war, had command of the artillery at Coutras (1587), and helped materially to decide the victory. He reached Ivry but an hour and a half before the battle, but was fortunate enough, though severely wounded, to capture the white standard with black crosses of Mayenne. He approved of the king's politic conversion, and throughout the whole of the reign remained his most trusted counsellor. His first task was to repair the ruinous finances of the realm, and to this gigantic labour he gave himself with an energy and persistence that entitle him to rank with Richelieu and Colbert among the few great ministers of France. Before his time not half the nominal sum raised from taxes

reached the treasury, the whole administration being an organised system of pillage; but Rosny made a tour through the provinces armed with absolute authority, personally examined the accounts, discovered the actual delinquents, and dismissed or suspended them, besides compelling them to disgorge their ill-gotten gains into the treasury. All this he effected with iron rigidity and persistence, heedless of the clamour and hatred of all the army of dishonest tax-gatherers and revenue-farmers, however high in station. In 1596, according to Henri Martin, the disposable revenue of the state was but nine millions of livres; in 1609 it was no less than about twenty millions, with a surplus as great in the treasury, and the arsenals and fleet besides in an excellent state of equipment. He brought actual order out of chaos, and would have done yet more for France but for the vast expenditure of the pleasure-loving king and his mistresses. Yet Sully was no far-seeing or philosophical financier, but only a dexterous master of expedients. He made no great innovations, but, if not a genius of creation, he was undoubtedly one of order. He distrusted manufactures as a source of prosperity, his main economic ideas summed up in his well-known aphorism, 'Labourage et pâturage sont les deux mannelles qui nourissent la France.' His own honesty has been impugned by hasty writers, but, even if he himself grew rich in his years of office, there is absolutely no proof that he ever robbed his master.

In February 1601 he became grand-master of the artillery, and in March 1606 he was created Duke of Sully. After the assassination of his master he was forced to resign the superintendence of finance, but was allowed to retain the care of the woods and the artillery, and was even presented by Marie de Médicis with a reward of 300,000 livres. But his reign was at an end, and ere long he retired to his estate, surviving till December 22, 1641. In his retirement his *Memoirs* were compiled by his secretaries, and submitted to him, being actually composed in the awkward and tedious fashion of a narrative addressed to himself. Here naturally his own actions are put in the most favourable light; yet, although the judicious student will by no means accept the whole as completely historical, the work remains a document of priceless value for the reign of Henry IV. Chapter vi., treating of the remorse of Charles IX. after St Bartholomew, was copied from an earlier MS., doubtless entirely Sully's own work, and is an admirable example of direct and vigorous writing. The first and second folio volumes were printed under Sully's own eye (undated, but really in 1634); the third and fourth volumes were printed at Paris in 1662. These last contain the famous anticipation of the League of Nations (see PEACE and INTERNATIONAL ARBITRATION). The scheme was no doubt Sully's rather than Henry's, although it may well be that its germ may have been found in the careless talk of the king with his trusted minister as they paced together the broad walk of the Arsenal gardens.

Sully was a harsh and unamiable man, of vast self-esteem and little humour; but his unpopularity was a natural enough fruit of his inflexibility of principle. His devotion to the interests of France and the person of the king it is absolutely impossible to gainsay.

The full title of his work is its best description: 'Mémoires des sages et royales Économies d'Etat, domestiques, politiques et militaires de Henri le Grand, l'exemplaire des rois, le prince des vertus, des armes, et des lois, et le père en effet de ses peuples français; Et des Servitudes utiles, obéissances convenables et administrations loyales de Maximilien de Béthune, l'un des plus confidents familiers et utiles soldats et serviteurs du grand Mars des Français; Dédiés à la France, à tous les bons soldats et tous peuples français.'

Marbault, secretary of Sully's chief rival, Du Plessis-Mornay, wrote a severe criticism on the *Mémoires*—the foundation of the unhistorical and calumnious article on Sully in the *Historiettes* of Tallemant des Réaux. The singular form in which the *Mémoires* was cast proved so intolerable to the 18th century that the Abbé de l'Écluse in 1745 re-edited the whole in ordinary form of narrative, but modernised and spoiled the work. The original text may be found in the collection of Michaud and Poujoulat (vols. xvi.-xvii.). See Sainte-Beuve's *Causeries du Lundi*, vol. viii.; also the books by Legouvé (1873), Gourdauld (3d ed. 1877), Bouvet de Cressé (1878), Dusieux (1887), and (Hailley (1888)); also Ritter's study of the *Mémoires* (Munich, 1871).

Sully-Prudhomme. RENÉ FRANÇOIS ARMAND (1839-1907), a great French poet, was born at Paris, and after the early death of his father was brought up by his uncle, a notary, for his own profession. He studied the sciences, law, and philosophy, but soon devoted himself entirely to letters, and in 1865 published his first volume of poems, *Stances et Poèmes*, which had the good fortune to gain and to deserve the praises of the veteran critic Sainte-Beuve. One poem, the 'Vase brisé,' at once became widely popular. Later volumes, *Les Épreuves*, *Croquis Italiens*, *Les Solitudes*, *Impressions de la Guerre*, *Les Destins*, *Les Vaines Tendresses*, *La France*, *La Révolte des Fleurs*, extended his fame as a poet of great delicacy of feeling, as well as subtlety and depth of thought. His finest poems are steeped in a serene but penetrating melancholy, and almost all reveal sincerity of inspiration, nobility of aims, and austere beauty of form. But he was ever a thinker wrapped in a poet's robe, and the things nearest his heart were the graver questions of life and death, of good and evil. Masterpieces of analytic subtlety are his didactic poems *La Justice* (1878) and *Le Bonheur* (1888). Other works are an accurate but somewhat harsh metrical translation of the first book of Lucretius (new ed. 1886); *L'Expression dans les Beaux Arts*, a contribution to the history of art; and *Réflexions sur l'Art des Vers* (1892). His *Œuvres Complètes* appeared in five volumes, 1882-88. He was elected to the Academy in 1881.

See Brunetière, *Poésie Lyrique et Littérature Contemporaine* (1894-95); Jules Lemaitre, *Les Contemporains* (1896); Gaston Paris, *Penseurs et Poètes* (1897); and studies by Hémou (1907) and Zyronski (1907).

Sulmona, the ancient Sulmo, a city of the Paeligni, lies 75 miles E. of Rome direct (107 by rail). It stands 1322 feet above sea-level, and has a cathedral of 1119, and some interesting mediæval churches and other buildings, but no Roman remains are preserved. Here were born Ovid and Pope Innocent VII. The ruins of the hermitage of Pietro di Morrone (afterwards Pope Celestine V.) lie on the mountain-side a few miles out of the town, adjacent to those of a Roman villa wrongly attributed to Ovid; and below is the former mother monastery of the Celestines (q.v.), now a prison. Pop. (1921) 18,797.

Sulphates. See SULPHURIC ACID; for sulphides and sulphites, SULPHUR.- SULPHITE PULP is wood pulp prepared with a solution of a sulphite by an alkaline earth that contains an excess of sulphurous acid, important in paper-making.

Sulphocyanates. See THIOCYANATES.

Sulphonal, a synthetical hypnotic now largely used, of complex composition, with the formula $(CH_3)_2C(SO_2C_2H_5)_2$. It forms colourless tasteless crystals, very slightly soluble in cold water. For sleeplessness it is given in doses of 15 to 45 grains, but opinions differ as to the place it will ultimately take in medicine.

Sulphonic Acid. See DYEING.

Sulphur is one of the most important of the non-metallic elements; S, atom. number 16, atom. wt. 32.06, sp. gr. of rolled sulphur 1.98, and of amorphous sulphur 1.957; sp. gr. of vapour 6.617 at 482° C., and 2.2 at 1040° C., atmospheric air being the unit of comparison for the vapour. At ordinary temperatures it exists as a solid, brittle, tasteless, and inodorous body, of a characteristic yellow colour, and insoluble in water. A piece of solid sulphur, heated to a temperature of 239° (115° C.), fuses into a thin yellow liquid; while in closed vessels it may by further heat be distilled, the boiling-point being about 836° (446° C.), and at this temperature it yields a deep yellow vapour of sp. gr. 6.617. When the sulphur-vapour comes in contact with cold air it condenses in the form of a fine yellow powder, known as *Flowers of Sulphur*. If fused sulphur be rapidly cooled it solidifies into a compact mass, of a granular crystalline texture; and if, in its liquid state, it be allowed to run into cylindrical wooden moulds, we obtain the ordinary roll-sulphur, or common brimstone. If allowed to cool slowly, it crystallises in long, glistening, deep yellow, oblique prisms, with a rhombic base, which, however, soon lose their most characteristic properties. As native sulphur is frequently met with in yellow crystals, whose form is derived from the octahedron with a rhombic base, it is obviously a dimorphous substance. Sulphur exists in several allotropic forms, red, black, or brown. When sulphur is heated it melts and forms a mobile amber-coloured liquid, which, by continued heat, gradually darkens, at the same time becoming more viscid, until a temperature of 356° (180° C.) is reached. Even though the heat be still continued, the temperature remains stationary for a time, but eventually it rises gradually to 500° (260° C.), the melted sulphur becoming less viscid. If at this stage it is poured into cold water it forms a tenacious ductile mass, which can be drawn out into threads having a certain amount of elasticity. In the course of a few hours these become brittle, and are seen to be crystalline in structure and in no way different from the original sulphur.

Sulphur is a bad conductor of heat, and the mere heat of a warm hand often causes it to crackle or even to fall to pieces, from the unequal expansion. It is an insulator of electricity, and becomes negatively electric by friction. It is slightly soluble in alcohol, ether, and the fatty oils; its best solvents being the bisulphide of carbon and chloride of sulphur. When it is heated in the air it takes fire at about 470° (243° C.), burning with a blue flame, and becoming converted into sulphur dioxide, whose pungent suffocating fumes are characteristic of sulphur. This element is second only to oxygen in its powerful affinity for other elements, with most of which it unites, and often in several proportions. With most of the metals it combines very readily, and in some cases with a development of light and heat; thus, silver and copper burn in sulphur-vapour just as iron-wire or zinc-foil burns in oxygen. In consequence of its power, with the aid of heat, of forming sulphurous acid with the oxygen of the air, and thus rendering the latter incapable of supporting combustion, burning sulphur may be usefully employed for the extinguishing of fire—as, for example, in chimneys.

Sulphur occurs very widely distributed in the mineral kingdom, partly free and partly combined with other elements. The free sulphur is either found pure in regularly formed crystals, or intimately mixed with earthy matters. Sulphur is usually plentiful in volcanic districts; most of what is used in Europe has been obtained from Sicily, but of late large quantities are recovered from the waste of soda manufacture, and sulphur has been actually exported from Newcastle

to Italy (see SODA, p. 500). Sulphur is found in many parts of the United States, and some Californian deposits have been utilised to a small extent, but have been unable to compete with Sicilian sulphur. In the form of sulphide, sulphur occurs abundantly in combination with iron, copper (iron and copper pyrites), lead (galena), zinc (blende), &c., the bisulphide of iron (or iron pyrites) furnishing most of the sulphur that is employed in the manufacture of sulphuric acid. Many of the metallic sulphides occur native, and form highly valuable ores. They are all solid at ordinary temperatures, and, with the exception of those of potassium, sodium, calcium, strontium, barium, and magnesium, are insoluble in water; they are, moreover, conductors of electricity. Many of them, especially of those that occur native, exhibit very brilliant and characteristic colours. The same metal may have several sulphides, and in general there is a sulphide for each oxide. The sulphides are, however, sometimes the more numerous. Sulphur is still more extensively distributed in the form of sulphates, as in the sulphates of lime, magnesia, baryta, &c. In the vegetable kingdom sulphur is a constituent of albumen (q.v.), and of the volatile irritant oils of mustard, garlic, asafoetida, &c.; moreover vegetable juices contain it in the form of certain sulphates. In the animal kingdom it is not only a constituent of the albuminous, fibrinous, and gelatinous tissues, but of the hair, saliva, bile, urine, &c.

The grosser impurities of sulphur are removed by crude processes of fusion and distillation at or near the place from whence it is obtained. What is called refined sulphur is purified by distillation in a large cast-iron still, and condensed in a receiver kept cool. When the vaporised sulphur is condensed in a large chamber it is obtained in the form of sublimed sulphur, or flowers of sulphur; but as the walls get hot it melts and collects on the floor, and is run into cylindrical wooden moulds, from which, when cool, it is taken out as roll or stick sulphur. The residue left in the retort is a mixture of sulphur with various impurities. Under the name of black sulphur, or *Sulphur vivum*, it is used in veterinary medicine, and for the purpose of dressing mouldy hops. Sulphur is thrown down from certain of its compounds (as from a strong solution of a polysulphide of calcium, sodium, or potassium) by dilute hydrochloric acid; it falls as a grayish-white, very fine, light powder, known in *Materia Medica* as milk of sulphur, or precipitated sulphur. The most common impurities met with in ordinary commercial sulphur are selenium and realgar (bisulphide of arsenic). Flowers of sulphur frequently exhibit a slight acid reaction, in consequence of a little sulphurous acid clinging to them. By rinsing them with water this impurity is at once removed.

Sulphur is extensively employed in the arts and manufactures, as in the manufacture of some matches, gunpowder, &c. When converted into sulphurous acid it is employed as a powerful bleaching agent, as also for the destruction of insects, fungi, &c.; but its chief consumption is in the manufacture of sulphuric acid.

The eight compounds of sulphur and oxygen, when combined with water, present the characters of acids. These acids have this composition:

Hyposulphurous acid.....	$\text{H}_2\text{S}_2\text{O}_3$
Sulphurous "	H_2SO_3
Sulphuric "	H_2SO_4
Thiosulphuric "	$\text{H}_2\text{S}_2\text{O}_4$
Disulphic "	$\text{H}_2\text{S}_2\text{O}_6$
Trithionic "	$\text{H}_2\text{S}_3\text{O}_6$
Tetrathionic "	$\text{H}_2\text{S}_4\text{O}_6$
Pentathionic "	$\text{H}_2\text{S}_5\text{O}_6$

We shall here notice the most important members of this group—the second, third, and fourth; the

third, *Sulphuric Acid*, is discussed in a special article. (The last four derive the essential part of their name from the Greek *theion*, 'sulphur'.)

Sulphurous Anhydride, or *Sulphur Dioxide*, SO_2 , occurs under the ordinary relations of temperature and pressure as a colourless gas, possessing the suffocating odour of burning sulphur. In its concentrated form it is quite irrespirable, and in a diluted state it excites cough. It not only is incapable of burning, but it rapidly extinguishes the flame of burning bodies; it supports the combustion of some metals. It is very freely soluble in cold water, which at 32° (0° C.) takes up nearly 69 times its volume of the gas, while at 75° (24° C.) it only takes up 32 volumes; the solution known as *Aqueous Sulphurous Acid* having at first the same smell and taste as the gas, but soon absorbing oxygen from the air, and becoming converted into sulphuric acid. By the action of cold sulphurous acid may be condensed to a colourless transparent limpid liquid, which freezes at -105° (-76° C.), forming a transparent crystalline solid. The specific gravity of the gas is 2.247 (atmospheric air being the unit), and that of the liquid is 1.49 (water being the unit), the solid being considerably heavier. Although dry sulphurous acid gas and dry oxygen when mixed exert no action on one another, there are many conditions under which sulphurous acid rapidly absorbs oxygen, and is converted into sulphuric acid—e.g. if the gas be dissolved in water; a similar action takes place under the influence of hydrated nitric acid, iodic acid, and certain metallic oxides. Hence sulphurous acid is a powerful reducing or deoxidising agent. This gas is a common and abundant product of volcanic action, and is occasionally met with in solution in the springs in volcanic regions. It may be prepared artificially by simply burning sulphur in the air or in oxygen gas, or by heating in a flask 4 parts of flowers of sulphur mixed with 5 parts of powdered black manganese, sulphurous acid and sulphide of manganese being the products, as shown by the equation $\text{S}_2 + \text{MnO}_2 = \text{SO}_2 + \text{MnS}$. In consequence of its solubility in water this gas should be collected over mercury. In addition to the uses of sulphurous acid as a bleaching agent, it is valuable both as a disinfectant agent and as a powerful antiseptic. But by far its most important use is in the manufacture of sulphuric acid. In combination with bases this acid forms the *sulphites*—a class of salts which, apart from the sulphite of soda, are of little importance, except for their power when moist of extracting oxygen, and thus acting as reducing agents. The salts of the sesquioxide of iron are reduced by them to salts of the protoxide.

Thiosulphuric Acid, $\text{H}_2\text{S}_2\text{O}_3$, formerly called Hyposulphurous Acid, is, as yet, only known in a state of combination with bases; for on attempting to separate the acid from the base the former becomes decomposed into sulphur and sulphurous acid. The most important of its salts is the *Hypo-sulphite of Soda*, $\text{Na}_2\text{S}_2\text{O}_3 + 5\text{H}_2\text{O}$, described in the article SODIUM. This and other soluble hypsulphites may be easily recognised by the facility with which they dissolve the haloid salts of silver, forming a solution of an extremely sweet taste, and containing a double hypsulphite of silver and soda, with an admixture of chloride, iodide, or bromide of sodium. It is this power of dissolving those salts of silver which are insoluble in water that renders the hypsulphite of soda useful in photography.

With hydrogen sulphur forms two compounds: (1) *Persulphide of Hydrogen*, an oily liquid, having the smell and taste of sulphuretted hydrogen; (2) *Sulphuretted Hydrogen*, H_2S , known also as Hydro-sulphuric Acid and Sulphydic Acid, a natural gaseous constituent of many Mineral Waters (q.v.),

as for instance Harrogate and Strathpeffer in Great Britain. It is formed spontaneously wherever organic compounds containing sulphur undergo putrefaction, as in stagnant sewers and cesspools and in waters charged with organic matter and sulphates. By acting on sulphide of iron with dilute sulphuric acid, sulphate of iron is produced and sulphuretted hydrogen liberated.

Sulphuretted hydrogen is a poisonous colourless gas, with the nauseous odour of rotten eggs. By pressure it may be liquefied and solidified. It is soluble in one-third of its volume of water; but the solution does not keep well unless preserved from contact with air. It is readily combustible, burning with a blue flame, and forming water, sulphurous acid, and usually a little sulphur. It has a weak acid reaction, but combines readily with bases forming sulphides. It is very poisonous, birds perishing in air containing $\frac{1}{1000}$ part, and dogs in air containing $\frac{1}{100}$ part of the gas. Owing to its presence in illuminating gas silver becomes tarnished in rooms where gas is burned, while librarians find the bindings of their books become corroded by the sulphuric acid eventually produced by the combustion of the gas. From its property of forming insoluble sulphides with most metals, sulphuretted hydrogen is the sheet anchor of the analytical chemist. These insoluble sulphides again are some of them produced in an acid solution, and some only in an alkaline one. It follows that by first acidifying the solution to be analysed and then adding the sulphuretted hydrogen certain metals will be removed as insoluble precipitates, while others will have been unaffected. On now adding an alkali a second portion will be removed, and so a working method of separating the metals can be devised. The simplest test for sulphuretted hydrogen at the mouth of a drain is the use of blotting-paper soaked in solution of acetate of lead. This rapidly turns brown in presence of the gas.

Sulphur combines with carbon to form *Bisulphide of Carbon*, CS_2 , a colourless, inflammable liquid, heavier than water, and having a disagreeable odour and taste. It is soluble in alcohol, but not in water, and it is a powerful solvent of fats, sulphur, phosphorus, and india-rubber. Owing to its high refractive power it is used in the construction of prisms. It may be obtained by heating fragments of charcoal to bright redness in a porcelain tube, and passing sulphur vapour along it. Its vapour when freely inhaled exerts an anæsthetic action similar to that of chloroform and ether. Workmen in caoutchouc or other manufactures in which bisulphide of carbon is used as a solvent suffer from prolonged exposure to its vapour, which produces headache, loss of appetite, impairment of vision and hearing, and causes general derangement of health by its deleterious action on the nervous system.

Sulphur combines with chlorine in several proportions, the most important of these compounds being the *Dichloride of Sulphur*, SCl_2 , and the *Chloride of Sulphur*, S_2Cl_2 . Both of them are liquids, and are formed by the direct action of the combining elements. The chloride is a yellow liquid which is decomposed by contact with water—sulphur, hydrochloric, and other acids being produced. It is capable of dissolving about 67 per cent. of sulphur at an ordinary temperature, and, like bisulphide of carbon, is extensively employed in vulcanising india-rubber. The dichloride of sulphur is formed by saturating the chloride with chlorine; a deep-red liquid, resembling the previous compound in most of its properties; it is decomposed by the sun's rays into the chloride and free chlorine.

Sulphur seems to have been known from the earliest times, and sulphuric acid was most probably known to the Arabians; the English manufacture of sulphuric acid dates, however, only from the 18th century. Sulphur is used for various purposes in medicine. It is given internally either as sublimed sulphur (flowers of sulphur) or as precipitated sulphur (milk of sulphur), in somewhat large doses, as a mild cathartic—generally combined with jalap and cream of tartar. The *Confection of Sulphur* of the Pharmacopœia is composed of sulphur, cream of tartar, and syrup of orange-peel rubbed together—the dose being from half an ounce to an ounce, or from one to two tablespoonfuls. In small doses sulphur is of great value in cases of atonic gout and chronic rheumatism. The external use of sulphur in the form of ointment has been already noticed in the article ITCH. It is also used externally in other cutaneous disorders, particularly in lepra and psoriasis; its application in the form of vapour is often of service.

Sulphuric Acid, H_2SO_4 , is the chemical name of the liquid commercially known as *Oil of Vitriol*—so called from its having been first produced by the distillation of green vitriol (sulphate of iron). It is an odourless, dense, oily-looking liquid, sp. gr. 1.842. When pure it is colourless, but usually it is of a straw to brown colour, derived from impurities which have fallen into it and been charred. It has all the properties of a typical acid, being intensely corrosive and changing vegetable colours. Exposed to the air it absorbs water, and when mixed directly with water great heat is evolved, the liquids contracting in bulk. It does not evaporate at ordinary temperatures, and dilute solutions spilt on cloth gradually become stronger till the acid begins to destroy the fibres of the cloth. Oil of vitriol is not the only hydrate of sulphuric acid. Three others are known to exist. When the fuming oil of vitriol of Nordhausen is exposed to a low temperature a white crystalline substance separates, which is a hydrate, pyrosulphuric acid, containing half as much water as the common liquid acid; its formula is $\text{H}_2\text{SO}_4\text{SO}_3$, and its fusing-point is 35°C . Again, a mixture of 49 parts of the strong liquid acid and 9 parts of water freezes at 8.3°C . and crystallises into splendid rhombic prisms, from which property it is often termed *glacial sulphuric acid*, with sp. gr. 1.780. Lastly, when a very dilute acid is concentrated by evaporation *in vacuo*, at $212^\circ (100^\circ \text{C})$, till it ceases to lose weight, there will be a resulting compound, consisting of 40 parts of the real acid and 27 of water, and represented by the formula $\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$. The compound formerly known as *anhydrous sulphuric acid* possesses none of the characteristic properties of an acid; see SULPHURIC ANHYDRIDE.

Sulphuric acid in its free state is a very rare natural product; although in combination with bases it is common in the animal and vegetable, and abundant in the inorganic kingdom. In plants it exists in the juices, and in animals in the blood and its derivatives chiefly in the form of sulphates of the alkalies; while in the mineral kingdom it occurs as gypsum (sulphate of lime), heavy spar (sulphate of baryta), celestine (sulphate of strontia), &c. It may be prepared on a small scale by boiling sulphur in *aqua regia* or in nitric acid, the sulphur becoming gradually oxidised into sulphuric acid. As a general rule, however, the commercial acid is employed even for laboratory experiments. In order to obtain the acid in a pure form, suitable for medical use or medico-legal analysis, it must be redistilled with sulphate of ammonia in a retort containing a few slips of platinum foil, the first and last portions being rejected. The distillation is attended with violent

concussions, partly owing to the high specific gravity of the acid, and partly owing to its high boiling-point, and this convulsive action is moderated mechanically by the platinum slips. Sulphuric acid thus prepared according to the directions of the British Pharmacopœia may be regarded as perfectly pure, presuming arsenic is not present. Strong sulphuric acid has comparatively little action on the metals except at a high temperature, when it dissolves them, and at the same time undergoes partial decomposition; the metal being oxidised by a portion of the acid which becomes decomposed into oxygen and sulphurous acid, and then uniting with a portion of undecomposed acid to form a sulphate. Silver, copper, mercury, arsenic, antimony, bismuth, tin, lead, and tellurium are thus acted on. Gold, platinum, rhodium, and iridium are not affected by the acid even at a boiling temperature. The more oxidisable metals, such as zinc, iron, nickel, and manganese, are readily soluble in the dilute acid, water being decomposed and hydrogen liberated, while the oxygen of the water unites with the metal; and the metallic oxide, at the moment of its formation, combines with the sulphuric acid to form a sulphate.

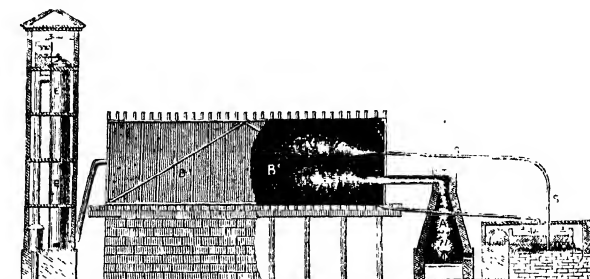

The *sulphates*—or salts formed by the combination of sulphuric acid with a base—are generally composed, as in the case of green vitriol, $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$, of 1 equivalent of acid and 1 of metallic oxide, with or without water of crystallisation. With the alkalis this acid also forms acid salts, as bisulphate of potash, and in a few cases—copper, for example—it forms basic salts. The insoluble sulphates, such as that of baryta, may be obtained by precipitating a soluble salt of the base by a soluble sulphate; thus, nitrate of baryta and sulphate of soda yield an insoluble sulphate of baryta and nitrate of soda, which remains in solution. The soluble sulphates may be prepared by dissolving the oxide or carbonate in dilute sulphuric acid, in those cases in which the metal itself is not readily attacked by the acid. Sulphuric acid and the soluble sulphates are easily detected by their yielding, with a solution of a baryta salt, a white precipitate of sulphate of baryta insoluble in acids.

Sulphuric acid is prepared on a large scale by three distinct processes—viz. by the distillation of green sulphate of iron—the original process of Basil Valentine (15th century); by the oxidation of sulphurous acid through the agency of nitrogen peroxide; and by the contact process. The first process is chiefly employed at Nordhausen in Germany. The sulphate of iron is distilled in earthen retorts, and the acid passes over into a receiver containing a little ordinary sulphuric acid, forming a brown fuming oily liquid, of about sp. gr. 1.900. This acid is known in commerce as Nordhausen acid, and is chiefly used for dissolving indigo.

The second method is that mainly followed in Great Britain, the germs of which were likewise discovered by Valentine. He observed that when the fumes of burning sulphur were collected under a bell jar, slightly moistened with water, a small quantity of liquid was deposited. This liquid, which was simply sulphuric acid, on being concentrated from its solution by boiling was long sold

as oil of sulphur at prices as high as 2s. 6d. per ounce. About the year 1740 the French chemists Lefèvre and Lévrier suggested that, by the use of nitre along with the sulphur, the operation might be conducted in close vessels, and a much greater quantity of acid might be produced. This idea was acted on in England by Dr Ward, who established works at Twickenham and Richmond, conducting his manufacture by burning the mixed sulphur and nitre in large stoppered glass receivers, into each of which a small quantity of water was first introduced. The substitution, in 1746, by Dr Roebuck of Birmingham, of lead chambers in place of the glass vessels may be regarded as essentially the establishment of the process of manufacture followed at the present day.

The first stage in the manufacture of sulphuric acid is the preparation of sulphurous acid by the burning of sulphur or of iron pyrites. Previous to the year 1838 Sicilian sulphur was almost exclusively used in the manufacture, but in that year

A, sulphur-burner, or furnace; B, lead chamber, shown in section at B'; C, steam-boiler; D, leaden pan; E, coke tower; S, steam-pipe, n, nitre pot.

the establishment of a monopoly of the sulphur trade by the Sicilian government, and its consequent increase in price, diverted the minds of manufacturers to the employment of iron pyrites (sulphide of iron). Iron pyrites is now much more used than sulphur, and the only hindrance to its universal adoption is the presence of foreign matter in the pyrites, the most deleterious being arsenical compounds; and it has hitherto been found impracticable to free the sulphuric acid wholly from the arsenious acid which renders it inapplicable for many purposes.

When sulphur is the material used for producing the sulphurous acid it is burned in an oven or 'burner' (A) of brickwork, having a sole or bottom of iron, termed the 'burner-plate.' Under this a small fire is at first lighted, which is allowed to go out after the sulphur has ignited. A little above the sulphur a small pot, called the nitre pot, n, is either placed on a stand or hung from the roof, filled with a quantity of either nitrate of soda or nitrate of potash, with sulphuric acid sufficient for its decomposition—8 or 10 lb. of the nitre with 5 or 6 lb. of sulphuric acid being allowed for every cwt. of sulphur. The decomposition of the nitre by the action of heated sulphuric acid furnishes nitric acid fumes, which go over into the chamber along with the sulphurous acid. The sulphurous acid readily abstracts from the nitric acid the additional oxygen required for its conversion into sulphuric acid, reducing the nitric acid to nitric oxide, NO. Nitric oxide in its turn quickly converts itself into nitric peroxide, by the abstraction of additional oxygen from the air that is constantly entering the chamber through the burners. Again, in the presence of moisture which is supplied by a

sulphuric acid, and again nitric oxide; which is ready once more to seize upon the oxygen of the air, and would continue so acting and reacting *ad infinitum*, were it not carried forward and out by the chimney.

The chamber is an immense box or room of lead, bound together with a strong framework of timber, and generally raised on arches several feet above the ground. Chambers vary in size from 60 to 140 feet in length, and from 20 to 40 feet in width and height. Curtains of lead proceeding alternately from the bottom to near the top, and *vice versa*, are very frequently used; they serve to retard the progress of the gases, and thus ensure the transformations desired. The floor of the chamber is covered with water, into which the sulphuric acid falls as it is formed; and when this solution attains a certain strength it is tapped off for concentration. When the gases reach the chimney, on account of the reactions of the nitrous compounds already explained, a large amount of nitrous acid would not only be wasted, but would also be deleterious to the neighbourhood, were steps for its recovery not adopted. This recovery is usually effected by means of a tower filled with coke, E, down which a constant stream of strong sulphuric acid trickles, the acid absorbing the nitrous fumes in their way upwards. Instead of a single chamber, curtained off or not as the case may be, sometimes three or five distinct chambers, connected by pipes, are employed, those communicating directly with the burners being termed working chambers, and the others receiving chambers, the last either acting as or communicating with a condenser or chimney.

When iron pyrites is used as the source of sulphurous acid suitable burners are used. In England these are arched chambers about four feet each way, on plan with furnace-bars placed a little above the ground. There are also the necessary doors and air holes. The pyrites is broken into pieces and spread in layers on the bars, which are previously heated to redness, and the heat evolved by the burning sulphur is thereafter sufficient for the fresh charges. The exhausted ore is frequently sufficiently rich in copper for its extraction; indeed, when there is as little as 2½ per cent. present in pyrites it is now recovered. In consequence of strong sulphuric acid absorbing both sulphurous acid and nitrous acid, the acid requires to be drained off from the chamber while the solution is comparatively weak, at which strength—viz. of a specific gravity of about 1.4—it is used for some purposes in the arts under the name of 'Chamber Acid.' This is concentrated by evaporating in lead pans, D, till it reaches the specific gravity of 1.6; then boiling in a platinum retort, on which strong acid does not act, even at high heat, or in large flint-glass retorts. In the process introduced in 1859 by Mr Glover the gaseous sulphuric acid from the sulphur or pyrites burners is not conducted direct to the lead chamber, but is first passed through a Glover's or denitrating tower, and there purified of nitrogen compounds, which are saved for use in the lead chamber.

The contact process consists in passing a mixture of air and sulphur dioxide over heated platinum; the platinum acts as a catalyst and brings about the union of the sulphur dioxide and oxygen forming sulphur trioxide, and by the action of water sulphuric acid is formed.

The manufacture of sulphuric acid is a very extensive industry; immense quantities of it being consumed in the manufacture of Soda (q.v.), in that of bleaching-powder, in calico-printing and dyeing, and in fact in most chemical operations

both in the manufactory and the laboratory. In medicine, a dilute sulphuric acid formed by gradually mixing the strong purified acid with water, or aromatic sulphuric acid (known also as *elixir of vitriol*) prepared by mixing sulphuric acid, rectified spirit, tincture of ginger, and spirit of cinnamon, is almost always employed. In doses of from ten to thirty minims, properly diluted, these preparations exert a strong astringent power, and are serviceable in all forms of passive hemorrhages, and in checking inordinate discharges when they arise from debility. Poisoning with this and other irritant acids is noticed at POISON.

Sulphuric Anhydride, SO_3 , is obtained by distilling fuming Nordlaussen sulphuric acid, a fibrous mass of silky crystals being deposited in the receiver. It may also be prepared by the distillation of anhydrous bisulphate of soda or by direct union. It is a tough solid, melting at 18.3°C ., and possessing none of the properties of an acid, not even affecting the skin. In contact with moisture much heat is developed, and it then possesses the corrosive properties of sulphuric acid. There are two forms of this compound, the α form, a liquid, and the β form, a solid.

Sulphuric Ether. See ETHER.

Sulphurous Acid. See SULPHUR.

Sulphur-root, a plant of the Umbelliferae, *Penicellum officinarum*, with small yellow flowers, long stamens, and linear leaflets. A rare inhabitant of the salt marshes of Essex and Kent, it was once highly esteemed as a medicinal plant, like *P. ostruthium* (mastwort), which grows in moist meadows, and has white flowers and ornate leaflets. Another rare British species is *P. palustre*. See also PARSNIP, DILL.

Sulpicians, an order of priests for training young men for the church, founded in 1645, and named from the church of St Sulpice (q.v.) in Paris.

Sulpicius Severus (363-410), a Christian historian, born in Aquitaine, who wrote a *Historia Sacra* from the Creation downwards, and a *Life of St Martin* (q.v.) of Tours.

Sultan (Arab., Turkish, and Persian *Sultān*), a Mohammedan ruling prince, as of Morocco, Zanzibar, or Egypt. The word was especially used of the Sultan of Turkey, who called himself Sultan of Sultans. The name of *Sultana* is given to the mother, wife, or daughter of a sultan. The old English form of the word was Soldan or Sowdan.

Sulu Islands, an archipelago stretching from Borneo north-eastwards to the Philippines. The 300 islands, most of them mountainous and all covered with luxuriant vegetation, have a total area of above 1000 sq. m. and a total pop. of 173,000. The inhabitants, Malays by race and Mohammedans by religion, were the terror of the neighbouring seas, owing to their bold piracy, until the Spaniards conquered them in 1876. The Spaniards evacuated Sulu in 1899, and by the 'Bates Agreement' the sultan of Sulu recognised the sovereignty of the United States. For a number of years the Americans were regarded with unconcealed hostility, but in 1913 the U.S. Philippine Commission created Sulu a civil department with Mindanao, and careful policy seems to have established peace. In 1920 Sulu and Mindanao came under the bureau of non-Christian tribes. The capital is the town of Sulu, officially called Joló, a picturesque town enclosed by a wall. The chief occupations are agriculture, fishing, and stock-raising, and there is a considerable production of sugar. The adjacent pearl-beds are very prolific, and pearls and the Sulu pearl-shell (*Manila pearl*) are sold in great quantities to European buyers.

Much hardwood is cut, including teak, and fruit is grown in abundance. Copra, dried fish, and abaca are exported, and rice, textiles, petroleum, iron, flour, &c. imported. See S. Y. Orosa, *The Sulu Archipelago and its People* (1923).

Sumach (*Rhus*), a genus of small trees and shrubs of the family Anacardiaceæ. They have small inconspicuous flowers in panicles or in corymbs, and the fruit a small, nearly dry drupe. The species are numerous, and are diffused over almost all parts of the world, except its coldest regions and Australia; some of them are useful in the arts and in medicine, and some are remarkable for their poisonous properties.

Venetian Sumach (*R. Cotinus*), known also as Wig Sumach, or Wig Tree, is a native of the south of Europe and west of Asia, and is often planted in Britain as an ornamental shrub. It has simple leaves, and hairy corymbs of fruit, which have a sort of resemblance to periwigs. The twigs and leaves dye yellow (see FUSTIC), and are used in tanning. The bark has been used as a substitute for Peruvian Bark. The seed resembles the almond in flavour. The very acid fruit of the Sicilian or Elm-leaved Sumach (*R. Coriaria*)—a native of the countries

Sumach (*Rhus Cotinus*), showing leaves, flowers, and fruit.

around the Mediterranean, with pinnate leaves, not unfrequent in British shrubberies—has been used as a condiment, and the seeds and the leaves medicinally as tonic and cooling. This species is also used for tanning and dyeing. Similar to this in its properties is the Virginian Sumach, or Stag's-horn Sumach (*R. typhina*), a native of eastern North America, and common in British shrubberies, which has the branches curiously crooked, and covered when young with a soft velvety down. It has pinnate leaves, with numerous leaflets, and is valuable as an astringent and refrigerant. The milky juice which exudes from incisions made in the bark affords a varnish. The flowers supply abundance of honey. The Smooth-leaved Sumach (*R. glabra*), a very similar species, also North American, has very acid leaves, and this species is sometimes troublesome as a weed. Of the acid and poisonous species the most important is the Poison Ivy (*R. Toxicodendron*) of North America, a shrub from 1 to 3 feet high (when it is also called Poison Oak), or a climber, with leaves of three leaflets, and a milky juice, which becomes black on exposure to air. The leaves have been used in medicine as a stimulant of the nervous system. Similar to this in properties are the Poison Sumach (*R. venenata*), with from 7 to 13 leaflets, also known as Poison Elder or Swamp Dogwood, and other North American species, the juice of which is very acid; even the emanations are injurious to some persons, who, from standing close to these plants, or from handling them, experience a cutaneous eruption with violent itching. The Varnish Sumach (*R. vernicifera*), a native of the mountains of Sze-chuan and Hupeh, yields a varnish much used in Japan for lacquer-work. *R. Metopium*

yields in great abundance a gummy resin, which in a pure state is yellow in colour, and of a hard brittle consistence. *R. succedanea*, a native of Japan, yields a tallow used instead of beeswax. See WAX.—The name Tanners' Sumach is given to the unrelated *Coriaria myrtifolia*, a shrub of the south of Europe. All parts, especially the sweet fruits, are extremely poisonous. *Coriaria* by itself forms the widely distributed family Coriariaceæ, related to Empetraceæ.

Sumatra (so called probably from the ancient town of Samudera in the north) is the largest of the Great Sunda Islands, and, after Borneo, of the Malay Archipelago, having an area not much less than that of Spain, calculated on very imperfect data at 163,000 sq. m. (or, including the numerous and important islands off the coasts, 178,000 miles). Towards the middle it is crossed by the equator, and it extends from 5° 40' N. lat. to 5° 59' S.

Barisan, or Chain Mountains, consisting of several more or less parallel ranges (7000 to nearly 12,000 feet high), with intervening plateaus and valleys—forms the framework of the island, which has a bold and frequently precipitous coast towards the west, but has been carried eastward by the formation of vast expanses of alluvial ground. Slates and clay-schists of high antiquity, with granite not so frequently visible, form the original kernel of Sumatra, which has been subsequently modified by Carboniferous strata, long afterwards by Tertiary breccias, sandstones, marls, and coal-beds, and still further by very extensive Post-tertiary deposits. Volcanoes have played a large part in embossing the surface. Of the numerous cones along the Bukit Barisan ranges about a dozen are still active, including Indrapura (the culminating peak of the island, 11,800 feet), Merapi (the most restless), Pasaman or Mount Ophir. In 1883 the southern end of the island was involved in the Krakatau (q.v.) eruption. The mountain-lakes, which are characteristic of the island, are largely of volcanic, and more especially of craterial origin; of these the most important are the Singkarah, the Korintji, the Ranau, and the Tobah. Towards the west the rivers of Sumatra are of necessity short and rapid, but several of the eastward streams, the Rokan, Siak, Indragiri, Djambi, and Palembang or Musi, grow to imposing rivers in their passage through the plains, and, being navigable for considerable distances, are important means of internal communication. The rivers are fed by an abundant rainfall; the average precipitation at Deli, for example, is 83 inches per annum. The clouds descend much lower than in other islands of the archipelago. The division of the seasons is of course quite opposite in the two halves of the island, lying respectively north and south of the equator. The N.W. monsoon is the prevailing wind over the southern portion; in the north the winds are varied. Hailstorms are not infrequent in the higher regions of the island. The Sumatra flora is exceptionally rich. Vast areas of the mountain regions are covered with virgin forest, a striking contrast to the vast prairies of alang (or lalang), that vigorous grass which seizes on every clearing not occupied by human industry. Though it only explored a small portion of the western side of the island, the Dutch expedition of 1877-79 collected 400 varieties of timber. The vegetation—contours of the island descend much lower than those of Java. In Java, for instance, the oaks do not grow below an altitude of 4500 feet; in western Sumatra they come down to within 500 or even 100 feet of sea-level. The humid climate and volcanic soil produce ideal conditions for agriculture. Rice,

sugar (from cane and the Arenga palm), coffee, pepper, coconuts and copra, sago, maize, sweet potatoes, yams have long been among the principal cultivated products. Introduced in 1863, the tobacco of the Deli district, grown by Dutch planters with coolie labour from China and Java, has become favourably known both in European and American markets. Since the beginning of the 20th century rubber-growing has become an industry of first importance, the climate being very suitable; the area under rubber, excluding extensive native plantations, is nearly half a million acres. Other recent introductions are the oil-palm (*Elais guineensis*) and Tea (q.v.); and there are a number of cinchona-tree estates. Other products are gums, mangrove bark, gambier, nutmegs, timber, rattan, fibres, and vegetable oils and fats. Boring for petroleum, especially in the districts of Perlak, Djambi, and Palembang, has come to be by far the most important mineral industry. There is an important coal-mining centre at Umbilin. It is a government undertaking, and was united with the west coast by rail in 1891. The iron deposits known to exist in the SE. are undeveloped. Tin is mined on several islands off the coast, notably at Banka, Billiton, and Singkep. Other minerals—gold, silver, precious stones, &c.—are found, but are of little importance, and the manufacturing industry is negligible. The chief town on the east coast is Medan (pop. 45,000), a town of rapid growth, with its port at Belawan-Deli. Padang (38,000), on the west coast, has its port at Emmahaven. There are railways in the west and north east, with a total length (including light railways and steam tramways) of 950 miles.

The Sumatran fauna is of peculiar scientific interest, and is clearly separated from that of Java. The birds and snakes are in the main Bornean. The Bornean forms, however, are almost entirely confined to the eastern side of the island; as soon as the naturalist crosses the Barisan Mountains he finds himself in a new region. The Orang-utan (of limited range and not abundant) and the *bru* (Malay name) or Meester Kees (Dutch), employed by the natives to gather their coconuts, are the most noteworthy of the numerous apes. The true tiger, the bimaug or Malay bear, the much-hunted rusa deer, the dainty kanchil deer, the panther, the Malay hog, the tapir, the two-horned Sumatran rhinoceros, the Sumatran elephant, and the Sumatran hare are characteristic forms. Among the commonest birds are Argus pheasants, hornbills, goatsuckers, and grakles (one species of the latter largely kept in cages for their parrot-like powers of speech). Both the python (15 to 20 feet long) and the cobra are of frequent occurrence, and the crocodile swarms towards the coast and ascends the rivers as far as the foot of the mountains. Sumatran butterflies are famed for their size and beauty.

Sumatra is peopled in the main by tribes of the Malay stock, differing very markedly, however, in degree of civilisation, custom, and language. An earlier non-Malay element is more or less distinctly represented. The chief races to be found are the Malays, the Battas (q.v.) or Bataks, the Lampongs, Redjangs, Lebongs, Achinese, &c. All these have their own languages, although generally Malay is understood all over. Hindu influences, which have left their mark in ruins of temples, religious customs, language, alphabets, &c., began to tell on Sumatra at a period prior to the 7th century. In the 13th Mohammedanism was introduced. The island became known in 1508 to Europeans through the Portuguese Lopez de Sequeira, whose fellow-countrymen were not long in founding trading stations on the coasts. The Portuguese were ousted by the Dutch towards the close of the

16th century. Begun in 1620 by their East India Company, the permanent Dutch occupation was not completely carried out round the coast till 1881, and much of the interior is still semi-independent and unexplored. The Dutch possessions were in the hands of the British between 1811 and 1816, and portions down till 1825. The residency of the East Coast was established in 1873; the government of the West Coast in 1819; and the residencies of Bencoele, Palembang, and Lampong respectively in 1824, 1825, and 1857. Atjeh, or Achin, (q.v.), only subdued after a long war (1875-79) and not pacified for many years later, was formed into a government in 1881. The total population of Sumatra in 1920 was 5,852,135 (Achin, 736,000; West Coast, 1,522,000; East Coast, 1,197,000; Bencoele, 257,000, &c.). Among the more important centres of population are Padang (38,000), Bencoele (9000), Palembang (74,000), Medan (45,000), and Djambi (11,311).

For literature on Sumatra, see *Aardrijkskundig Woordenboek van Ned. Ind.* (1869); Kan in *Tijdschrift van het K. Ned. Aard. Gen.* (1889). See especially Marsden's classical work, *The History of the Island of Sumatra* (1783); the Memoir of Sir Stamford Raffles; Veth, *Midden-Sumatra* (1882); Kieistra, *Atjeh Oorlog* (1885-86); Wallace, *Malay Archipelago*; Forbes, *A Naturalist's Wanderings in the E. Archipelago* (1885); Hagen, *Die Pflanzen und Thierwelt von Deli auf der Ostküste Sumatras*, in *Tijds. van het N. Aard. Gen.* (1890); D. G. Stibbe (ed.), *Encyclopedie van Nederlandsch-Indië* (1922); A. Cabaton, *Java and the Dutch East Indies* (trans. 1911); A. S. Walcott, *Java and her Neighbours* (1914).

Sumbawa, one of the chain of the Sunda Islands to the east of Java, lies between Lombok (on the west) and Flores (on the east). Area, including the adjacent islands, about 5200 sq. m.; pop. about 75,000. The Sumbawan natives are of Malay race, but there are also Buginese and Macassar immigrants, and wild mountain tribes. They are divided between four native rulers, who owe allegiance to the Dutch governor of Celebes. The islands are mountainous but fertile, and yield rice, tobacco, cotton, sandalwood, &c. In 1815 an eruption of Tambora, the loftiest peak on the island, whereby the altitude was decreased from 14,000 to 7670 feet, depopulated the kingdoms of Tambora and Papekat, 12,000 lives being lost, and great damage done to the whole island by the ashes.

Sumér, Sumir. See BABYLONIA.

Summer Isles, a group of twenty rocky islets off the west coast of Scotland, near the entrance of Loch Broom, an inlet in the north-west of Ross-shire. The largest, Tanera, measuring 1½ by 1½ mile, rises 406 feet.

Summer Time, a device first adopted by Act of Parliament in 1916 and now governed by an act of 1925, whereby during the summer months the time throughout the country is advanced one hour beyond Greenwich Mean Time. The legal duration of Summer Time is from 2 A.M. on the day next following the third Saturday in April (or, if that day is Easter Day, then one week previous) to 2 A.M. on the day next following the first Saturday in October. The same limits for Summer Time are in use in France and Belgium. The measure was at first one of war emergency, calculated to save light and fuel by bringing an extra hour of daylight into the ordinary working day. Its success, however, in spite of much opposition, mostly from agricultural interests, justified its continuance as a regular institution. Although only adopted in this country in 1916 the scheme—or a similar one—was suggested in 1907 by William Willett (1856-1915), a Chelsea builder, and even got to the stage of a Parliamentary Committee, before being abandoned.

Summons, in English law, means generally a writ or order directed to a party to appear and answer some complaint before a court or judge. All actions in the High Court now begin with the issue of a writ of summons. A summons is usually the first step in summary proceedings before magistrates. In Scotland the first writ in an action is called a summons; and the term is also in use in the colonies and in the United States.

Sumner, CHARLES, an American statesman conspicuous from 1845 onwards till his death, was born in Boston, January 6, 1811. The founder of the family in America was William Sumner, a native of Oxfordshire in England, who settled in Massachusetts about 1635. Charles Pinckney Sumner, of whose nine children Charles and his twin-sister Matilda were the eldest born, held the post of sheriff of Suffolk county from 1825 till shortly before his death in 1839, and was highly respected for his probity and independent spirit, despite his stiff and formal manners and his outspoken anti-slavery sentiments at a time when such opinions were generally unpopular and were rarely expressed by persons in official station. Educated at the Boston Latin School and at Harvard College, where he graduated in 1830, Charles Sumner entered the law-school in the following year, and in 1834 was admitted to the bar. An enthusiastic student of the principles of law, he had little taste for the ordinary routine of office work, and hence, though occasionally engaged in important cases, he failed to secure a remunerative practice or to acquire reputation as a pleader. He found more congenial employment as a lecturer on legal topics and a contributor to law journals and compilations. In private life he was greatly esteemed for his sincerity and earnestness, his general cultivation, his stainless character, and his cheerful and kindly demeanour, though too devoid of humour, wit, and playful fancy to become a favourite in ordinary social circles. In December 1837 he went to Europe, where he remained till May 1840, pursuing with his habitual assiduity the study of jurisprudence at the Sorbonne and elsewhere, widening the general range of his knowledge, and cultivating the acquaintance, especially in England, of the most eminent men, of whom his letters at this period, published since his death, give many graphic sketches and lively anecdotes. On his return to Boston he resumed his professional practice, but with even less liking for the drudgery of its details than he had before evinced. Abstract discussion had stronger attractions for him, and he first came into prominence by a civic oration, on July 4, 1845, which, under the title of 'The True Grandeur of Nations,' was simply a vehement denunciation of war, as 'utterly and irreconcilably inconsistent with true greatness.'

It was because the current of events was then bringing to the front a subject involving the deepest moral considerations that Charles Sumner was drawn into the vortex of political life. A member of the Whig party by descent and associations, he took but a languid interest in politics until the threatened extensions of negro slavery over newly-acquired territory awakened a spirit of resistance in the free states. Despite the efforts to stifle agitation by party leaders and all who feared for the results, the growth and preponderance of the slave power, with the foundations on which it rested, became the absorbing question of the day, entering like a wedge into established political combinations and thrusting aside all other issues. Sumner was at one with the Abolitionists in asserting the inherent and total sinfulness of slavery; but unlike them he maintained that the constitution did not recognise property in man, and that slavery, a purely

sectional institution, could be combated in the political arena, and so crippled by legislation that it would necessarily dwindle and become extinct. In 1848 he joined with others holding similar views in the formation of the Free Soil (q.v.) party, in which his abilities, learning, high character, and social standing gave him a prominence which he cannot be said to have sought by any purely ambitious efforts. Nominated for congress in the same year, he was easily defeated by the Whig candidate, R. C. Winthrop; but in April 1851, after a protracted contest, he was elected to the national senate as the successor of Daniel Webster, by the combined Free Soil and Democratic votes of the Massachusetts legislature. The post thus gained he continued to hold during the remainder of his life, being re-elected in 1857, 1863, and 1869. At the outset he stood alone in the senate as the uncompromising opponent of slavery, and his elaborately prepared speeches, characterised alike by their studied array of facts and arguments and their bold denunciatory tone, excited universal attention, and were perhaps equally effective in winning support in one section and inflaming hostility in the other. The latter spirit found vent in an act which produced a more startling and profound impression throughout the northern states than any speech could have made. On the 22d May 1856, while sitting at his desk in the senate chamber after an adjournment, Sumner was suddenly assaulted by Preston S. Brooks, a member of congress from South Carolina, and by repeated blows on the head with a heavy cane prostrated on the floor in a state of insensibility. His injuries were in fact so severe as to incapacitate him for public life during nearly four years, while his vacant chair was pointed to as the most eloquent reminder of the violent and lawless animosity against which the advocates of freedom must prepare to contend. He resumed his seat at the close of 1859, and in June 1860 delivered a speech on the question of the admission of Kansas as a free state, which he published under the title of *The Barbarism of Slavery*.

But the predestined course of events no longer needed any impulse from oratory, and the attempts to arrest it by conciliatory offers, in which Sumner naturally took no part, only pointed more plainly to the inevitable collision. The secession of the southern states left the Republican party in full control of both houses of congress, and in March 1861 Sumner was elected chairman of the senate committee on foreign affairs. His interest in domestic affairs was still centred on those in regard to which moral principles could be adduced as the proper basis of political action. He was urgent for the emancipation of the slaves, and not less strenuous, after this had been secured, in obtaining for the coloured race the fullest civil and political equality with the whites. He supported the impeachment of President Johnson, regarding it as a continuation of the struggle for the overthrow of slavery, and he was foremost in opposing President Grant's project for the acquisition of San Domingo, on the ground that the assent of Bacz, the president of that republic, had been given in opposition to the wish of the inhabitants. His conduct on this occasion led to his exclusion in 1871 from the chairmanship of the committee on foreign relations, and his continuous and acrimonious censures on Grant's administration brought about a rupture with the leading politicians of the Republican party which was rendered complete by his support of Greeley as candidate for the presidency in 1872. But, although the result of the election left him in the ranks of a discontented minority, his course had been too evidently dictated by principle to allow of his sinking in esteem with the mass of the party, and the breach was gradually

closing when his death, at Washington, on the 11th March 1874, obliterated all asperities, and left only the remembrance of his great services and distinguished career.

Sumner's position in the field of politics was in some respects unique. From first to last he was an independent rather than a partisan. Nature had given him neither the submissive temper of the follower nor the tact, the shrewdness, the persuasive eloquence, and the skill in the management of men and of affairs which are the requisites of leadership. Expediency had no place in his thoughts, flexibility in his disposition, or snavity in his methods or language. Had it been otherwise he might, on the death of Lincoln, have succeeded to the highest place in the national confidence and regard. For his position was a commanding one, owing to his unimpeachable integrity, his unflinching courage, his singleness of purpose and consistency of action, his freedom from every suspicion of intrigue or self-seeking, and his identification both as a victim and a victor with the cause to which he had devoted all his energy and talents. In person he was tall and well proportioned, and, though his features were rugged, the expression of his countenance was engaging. His speeches lacked the charm of spontaneous eloquence, but they were effective as essays or lectures, and furnished his supporters with an arsenal of arguments and illustrations. That his frequent violence in public debate sprang from no bitterness of spirit is attested by his freedom from vindictiveness, his cordiality in private intercourse, and the warmth and fidelity of his friendships. His nature was too open to admit of misconception, and the poet Longfellow, with whom he lived in intimacy, described him as the whitest soul he had ever known.

See his *Works* (15 vols. 1870-79); his *Memoirs and Letters* by Pierce (4 vols. 1877-93); and shorter Lives by Anna Davies (1892), Storey (1900), and Haynes (1909).

SUMNER, JOHN BIRD, Archbishop of Canterbury, was born in 1780, and educated at Eton and Cambridge. Successively rector of Mapledramham (1818), Bishop of Chester (1828), and Primate of all England (1848), he was distinguished for his conciliatory disposition and moderate views, and wrote works on *Apostolical Preaching*, *The Moral Attributes of the Creator*, and *Evidences of Christianity*. He died 6th September 1862.—His brother, CHARLES RICHARD (1790-1874), was Bishop of Winchester, and his Life was published in 1876.

Sumptuary Laws (Lat. *sumptus*, 'expense'), laws passed to prevent extravagance in banquets, dress, and private expenditure. They abound in ancient legislation. The Locran legislator, Zalenus, 450 B.C., ordained that nobody should drink undiluted wine; and in Solon's code there were many sumptuary enactments. At an early period in Roman history the Censors, to whom was entrusted the superintendence of public and private morality, punished with the *notatio censoria* all persons guilty of luxurious living; but as the love of luxury grew with the increase of wealth and foreign conquest various legislative enactments were passed with the object of restraining it. The Lex Orchia, 187 B.C., limited the number of guests to be present at a feast; the Lex Fannia, 161 B.C., regulated the cost of entertainments. There were also the Lex Didia, Lucretia, Cornelia, Emilia, and others, most of them passed in consequence of the practical disregard of the similar laws that had preceded them; but they all seem to have been habitually transgressed in the later times of the Republic. Julius Cesar, Augustus, and other rulers also made laws against luxury.

Sumptuary laws were in great favour in the

legislation of England from the time of Edward II. down to the Reformation. Statute 10 Edward III. chap. 3 narrates that 'through the excessive and over-many costly meats which the people of this realm have used more than elsewhere many mischiefs have happened; for the great men by these excesses have been sore grieved, and the lesser people, who only endeavour to imitate the great ones in such sorts of meat, are much impoverished, whereby they are not able to aid themselves, nor their liege lord, in time of need as they ought, and many other evils have happened as well to their souls as their bodies; and enacts that no man, of whatever condition or estate, shall be allowed more than two courses at dinner or supper, or more than two kinds of food in each course, except on the principal festivals of the year, when three courses at the utmost are to be allowed. All who did not enjoy a free estate of £100 per annum were prohibited from wearing furs, skins, or silk, and the use of foreign cloth was allowed to the royal family alone. Act 37 Edward III. declares that the outrageous and excessive apparel of divers people against their estate and degree is the destruction and impoverishment of the land, and prescribes the apparel of the various classes into which it distributes the people; it goes no higher than knights, but there are minute regulations for the clothing of women and children. This statute, however, was repealed the next year. In France there were sumptuary laws as old as Charlemagne, prohibiting or taxing the use of furs; but the first extensive attempt to restrict extravagance in dress was under Philip IV. By an edict of Charles VI. no one was allowed to exceed a soup and two dishes at dinner. Frederick the Great and other German princes endeavoured to suppress the use of coffee as a harmful luxury. Sumptuary laws continued to be introduced in England in the 16th, in France as late as the 17th century; and burial in woollen, prescribed by English law from 1678 till 1815, was akin to them, though its primary object was to lessen the importation of linen. The Scottish parliament attempted to regulate the dress of the ladies, to save the purses of the 'poor gentlemen their husbands and fathers'; and statutes were passed against superfluous banqueting, and the inordinate use of foreign spices 'brought from the parts beyond sea, and sold at dear prices to monie folk that are very unwill to sustain that cost'. Neither in England, Scotland, nor France do these laws appear to have been practically observed to any great extent: in fact, the kings of France and England contributed far more, by their love of pageantry, to excite a taste for luxury among their subjects than by their ordinances to repress it. Froude has suggested that such statutes may have been regarded, at the time when they were issued, rather as authoritative declarations of what wise and good men considered right than as laws to which obedience could be enforced. Enactments of this kind have long been considered to be opposed to the principles of political economy. Most of the English sumptuary laws were repealed by 1 James I. chap. 25; but regulations of a similar kind survive in the university statutes of Oxford and Cambridge. There is a trace of the same principle in the present-day taxation of luxuries—wine and spirits, tobacco, tea, and coffee (though mainly with a view to regulating the incidence of the tax), and in the duties on male servants, armorial bearings, &c. And one reason sometimes urged for the suppression of the liquor traffic is the diminution thereby to be effected in wanton waste and pernicious luxury. In Montenegro strong laws were passed in 1883 against gloves, umbrellas, and non-national costumes.

Sumter, FORT (named after General Thomas Sumter, 1734-1832, an active partisan leader of the revolutionary war), an American fort associated with both the beginning and the end of the civil war, was built of brick, in the form of a truncated pentagon 38 feet high, on a shoal, partly artificial, in Charleston Harbour, $3\frac{1}{2}$ miles from the city. On the secession of South Carolina in December 1860, Major Anderson, in command of the defences of the harbour, abandoned the other forts, and occupied Fort Sumter, mounting sixty-two guns, with a garrison of some eighty men. The attack on the fort was opened by General Beauregard on April 12, 1861, and it surrendered on the 14th: this event marked the beginning of the war. The Confederates strengthened it, and added ten guns and four mortars. In April 1863 an attack by a fleet of monitors failed. In July batteries were erected on Morris Island, about 4000 yards off, from which in a week 5000 projectiles, weighing from 100 to 300 lb., were hurled against the fort; at the end of that time it was silenced and in part demolished. Yet the garrison held on amid the ruins, and in September beat off a naval attack; and in spite of a forty days' bombardment in October-December 1863, and for still longer in July and August 1864, it was not till after the evacuation of Charleston itself, owing to the operations of General Sherman that the garrison retired, and the United States flag was again raised, April 14, 1865; an event soon followed by the evacuation of Richmond and the Confederate surrender.

Sun, the star which governs, warms, and illuminates the earth and the other bodies forming the solar system. Early observations were necessarily confined to records of its motions and eclipses, by means of which predictions were made even in ancient Chaldaea, Egypt, and China (see *ASTRONOMY*). The apparent motions of the sun, determining the amount of light and heat received at different parts of the earth, naturally give us our principal time-measures (see *DAY, YEAR, SEASONS*). For long the observation of these formed perhaps the chief part of astronomy. But when Copernicus showed that the sun was really the centre of our system, and Galileo discovered the moons of Jupiter, the idea of a community of nature between the sun and our world—the earth circling around the sun as the moons around Jupiter—began to take firm root in men's minds. Newton's discovery of the law of gravitation greatly aided this process. The idea that the sun shone because it was composed of mysterious fiery elements faded away, and men began to ask after its real constitution, and seek the secret of its stores of energy.

(1) *The sun's distance* was the first problem to be attacked. Aristarchus of Samos, realising that the moon shone by reflected light from the sun, argued that the moon would be exactly half full when the directions of the sun and earth as seen from the moon were at right angles. From measures of the angular distance between the sun and the moon, when the moon appeared to be half-full, he concluded that the sun was eighteen times as distant as the moon. The method is right in principle, but in practice it is not possible to say when the moon is exactly half-full with sufficient precision. This value was generally accepted till the time of Kepler, who showed that the distance must be at least three times as great. The first determination which approaches to what is now known to be the distance was made between 1670 and 1680 by Cassini. He found the sun's distance indirectly from a determination of the distance of Mars when in opposition and therefore nearest the earth. The relative distances of the planets from the sun are known by Kepler's Laws (q.v.), and thus the measure of the distance between any two

is sufficient to give the absolute distances of all. To obtain the distance of Mars, observations to determine its Parallax (q.v.)—or displacement among the stars due to its being seen from different standpoints—were made simultaneously at Paris and Cayenne in South America. The equatorial horizontal parallax of the sun—i.e. the angle subtended by an equatorial radius of the earth—was thus found to be $9\cdot5''$, corresponding to a distance of 87 million miles. Flamsteed obtained $10''$, Picard $20''$, and Lahire $6''$ by the same method. It was pointed out by Halley in 1716 that the transits of Venus might be used to determine the sun's distance. At rare intervals this planet passes between the earth and the sun, and may be seen crossing the sun's disc as a black spot. At these times Venus is only 25 million miles from the earth, and seen from widely different stations on the earth its projection on the sun's disc will be different. In the diagram E is the earth, V Venus, and S the sun. An observer at A, a station on the

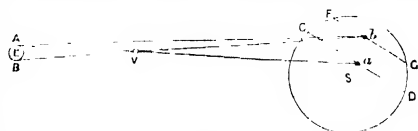

Fig. 1.

northern part of the earth, will see the planet projected on the sun at a , while a southern observer will see it at b . The observer at A sees the planet move along the chord (CD), and by his observation of the exact duration of the transit, the length of (CD) can be determined in minutes and seconds of arc, as the motion of Venus is known. Similarly, from the observations of the observer at B the length of FG is determined. The angular distance ab between these two chords can then be calculated. This is the angle aAb . From the triangle AVb, A and b being very small angles, it follows that $b:A = AV:Vb$, and the ratio of $AV:Vb$ is known. Hence the angle AAb , or the angle subtended by AB at the distance of the sun, is found, and thus from the calculated distance of AB in terms of the earth's radius, the parallax of the sun is found. The parallax deduced by Encke in 1824 from the observations of the transits of 1761 and 1769 was $8\cdot6''$, corresponding to a distance of 95 million miles. The next transit of Venus (1874) was carefully observed by expeditions sent all over the world by various governments; but the results were disappointing from the observational difficulties of determining the times at which the transits began and ceased, because of the great brightness of the sun.

In the year 1877 Sir David Gill made observations of Mars near opposition from the island of Ascension. Owing to the earth's rotation the observer is carried between morning and evening from one side of the earth's centre to the other. This difference of position serves as a base for the measure of parallax. With a heliometer Gill made a series of measures of the position of Mars with respect to neighbouring stars, and thus determined its parallax. The year 1877 was chosen because, owing to the eccentricity of the orbit of Mars, it was then unusually near the earth. Very accurate results were obtained, but it was seen that the greatest source of error arose from Mars having a sensible disc and not being, like the stars, a point in the telescope. Accordingly, in 1888 and 1889, Gill made at the Cape observations of the small planets Victoria, Iris, and Sappho, and deduced from them the value $8\cdot802''$ for the sun's parallax, corresponding to a distance of 92,874,000 miles. In 1898

a small planet, Eros, was discovered which comes much nearer the earth than any other planet. In 1900 extensive series of observations were made by many observatories, mainly photographic, to utilise the opposition of Eros to determine the solar parallax. The result derived by Mr Hinks from these numerous observations is 8.806"; this result agrees with Gill's to less than 50,000 miles in the deduced distance of the sun.

The methods we have described may be classified as 'trigonometrical' or 'surveying' methods. The sun's distance may be found by two wholly different methods. In 1675 the Danish astronomer Römer discovered that the eclipses of Jupiter's satellites by the shadow of Jupiter took place earlier than their predicted times when the earth was nearer than its mean position to Jupiter, and later when it was farther from its mean position. From these observations he determined the velocity of light. This procedure may now be reversed, since the velocity of light has been measured with all necessary accuracy by physicists in their laboratories. The Constant of Aberration (q.v.), which has been carefully determined, also gives the ratio of the velocity of the earth in its orbit to that of light. Thus the earth's velocity may be determined, and as its orbit is described in a year the distance from the sun follows readily. It is also possible by spectroscopic observations of stars to determine the ratio of the earth's velocity to that of light, and the solar parallax has been found with considerable accuracy in this way by Küstner and by Hahn.

The other methods may be described as 'gravitational.' An inequality in the sun's motion due to the fact that the earth each month moves round the centre of gravity of the moon and itself; an inequality each month in the movement of the moon depending on the sun's parallax; and the motion of the node of the orbit of Venus on the ecliptic due to the earth's attraction, all furnish means of determining the sun's distance.

(2) The sun's motion in space is ascertained in two ways. Analysis of the proper motions of Stars (q.v.) gives the direction of the motion, and its amount can be roughly determined from a knowledge of stellar parallaxes. The velocity is found more accurately from a comparison of spectroscopic determinations of the velocities of stars in the line of light, and the direction may also be obtained in this way. The direction of the sun's motion is towards the point in the sky whose R.A. is 18 h. and Dec. +30°. The amount is 12½ miles a second, or four times the distance from the earth to the sun in one year.

(3) The rate at which the sun is radiating heat is determined by measuring the amount received on a given surface exposed perpendicularly to the sun's rays. Pouillet in 1837 concluded that 1.76 calories were received per minute on a square centimetre. As much heat is absorbed by the earth's atmosphere, allowance is made for this as far as possible by taking the observations on a high mountain. The latest result is 2.25 calories, or sufficient to raise one cubic centimetre of water by 2.25° centigrade. If the radiant energy received from the sun could be transformed into mechanical energy, it would amount to three horse-power for every square yard exposed to the sun. The rate at which energy is being radiated from the sun's surface is easily calculated from the above figures to be approximately 100,000 calories per minute for each square centimetre. This would be sufficient to melt a layer of ice on the sun's surface 50 feet thick in one minute. The mechanism by which this radiation is maintained is by the constant flow of heat from the sun's interior to its surface, partly by radiation and partly by convective currents.

The temperature of the sun varies very rapidly

near the surface. From arguments based on Stefan's law that the radiation varies as the fourth power of the temperature, Wilson and Gray and Very have found by comparison of the heat received from platinum raised to a known temperature, with that received from the sun, a temperature of approximately 6000° centigrade. A similar result has been derived from the position of the maximum intensity of the continuous light in the solar spectrum, and recently by Saha from the nature of the absorption lines. These results give the temperature at which the surface of the sun, considered as a perfect radiator, would need to be maintained for the same amount of heat to be received by the earth.

The radiation of heat from the sun takes place at a rate which would reduce its temperature by about 2° centigrade annually. It is known from geological evidence that the sun's temperature cannot be diminishing at anything like this rate. Heat is acquired by the contraction of the sun under the effect of gravitation, and a shrinkage which would be too small to be detected in the diameter of the sun would be sufficient to compensate for the immense amount of heat radiated into space for a few million years. Taking the estimate of the age of the earth as a thousand million years, it is found that contraction is wholly insufficient to supply the loss of energy by radiation. At the high temperature of the interior, which is of the order of a million degrees centigrade, it is supposed that some of the internal energy of the atoms may be liberated and find its way to the sun's surface in the form of heat.

(4) The Solar Spectrum (q.v.) consists of a bright band crossed by dark lines. The dark lines are the source of our knowledge of the chemistry of that gaseous layer of the sun where the absorption which has produced them has taken place. From careful maps of the solar spectrum by Rowland, and comparisons with the spectra of terrestrial elements, it is found that the sun contains hydrogen, oxygen; carbon, silicon; sodium, potassium, magnesium, calcium, strontium, barium; aluminium, chromium, iron, nickel, cobalt, manganese; lead, zinc, tin, copper, silver, palladium; titanium, vanadium; scandium, yttrium, zirconium, lanthanum, cerium, erbium, ytterbium, europium, neodymium, gallium, and dysprosium. The principal elements not found in the solar spectrum are nitrogen, phosphorus, sulphur, fluorine, chlorine, bromine, and iodine; we cannot affirm that they are not present. Helium is in the spectrum of the sun's chromosphere, not in the ordinary solar spectrum.

(5) The surface of the sun may be examined visually by the use of dark glasses in front of the eyepiece of the telescope, or some other means of diminishing the light; by drawing the eyepiece a little out of focus and projecting an image of the sun on a screen; or by photography, with suitable means for securing sufficiently short exposures. It is found that the sun becomes less bright as the limb is approached; this holds especially for blue light, and is therefore most conspicuous in photographs. The existence of a *darky layer* above the sun's surface is indicated in this way. The sun's surface or *photosphere*, when examined under sufficiently steady atmospheric conditions, presents a mottled appearance, compared by Langley and Janssen to *rice grains*. The separate grains are about 400 miles in diameter, and may be hypothetically considered as the tops of long columns in which heated matter from the sun's interior rises to the surface. The *reversing layer* is a term applied to the part of the photosphere near the surface, where the absorption takes place which produces the Fraunhofer lines in the spectrum.

One of the earliest discoveries made after the

invention of the telescope was the existence of spots on the sun. Occasionally these are sufficiently large to be seen with the naked eye when protected from excessive glare by fog or dark glass. They have three well-marked areas, distinguished by different degrees of blackness—the *penumbra*, the *umbra*, and the *nucleus*. In their neighbour-

hood bright patches known as *faculae* are usually observed. Sun-spots are not found in all parts of the sun's surface, but only between the limits of 5° and 45° of solar latitude, both north and south of the equator. Sometimes the sun has many spots, and at other times is entirely free from them. In 1843 Schwabe of Dessau announced the important discovery that these periods of spot-activity occurred at regular intervals of ten years. Wolf in 1852 corrected this to 11.2 years. This is a mean period, as the individual periods vary considerably. Associated with this period is a drift of the spots in latitude. At sun-spot minimum the few spots there are occur either near the equator or far from it. As the number of spots increases the number near the equator becomes less, and those at a distance are in a lower latitude. These changes are associated with changes in the form of the sun's *corona*, and, what is very remarkable, with the frequency of magnetic storms and *aurores* on the earth's surface—magnetic storms being frequent at sun spot maximum. Some evidence has been brought forward by Mr Maunder in support of the hypothesis that electrified particles shot out from sun-spots reach our atmosphere and start magnetic storms.

In the spectra of sun-spots a large number of lines have been identified as due to titanium oxide, magnesium hydride, and calcium hydride. The existence of these compounds shows that spots are at a lower temperature or higher pressure than the reversing layer. In 1898 Hale proved that the apparent widening of certain lines in the spectra of spots was in some cases a doubling of the lines. He showed that this arose from the circular polarisation of the light from the spots, and established by experimental evidence that the phenomenon was what is known as the 'Zeeman' effect due to the existence of an intense magnetic field in sun-spots. How this arises has not yet been ex-

plained, but the tentative hypothesis of the rotation of electrified particles round the spot has been put forward. Photographs taken in the monochromatic light (see below) of the red hydrogen line *H α* show that vortical motion exists in the neighbourhood of spots. The existence of other phenomena which bear on the sun's physical condition has been revealed by total solar eclipses. At these times the immediate surroundings of the sun, which are usually invisible owing to the glare produced by the diffusion of sunlight in the atmosphere, are disclosed. Two remarkable features, the *prominences* and the *corona*, have been discovered in eclipses. The prominences are great tongues of flame which stand out from the sun's surface, sometimes reaching distances of 50,000 miles. Janssen discovered in the eclipse of 1868 that the spectrum of a prominence consisted of bright lines, and not, like that of the sun itself, of a bright band crossed by dark lines. Prominences, therefore, consist of luminous gas, of which hydrogen is often a main constituent. Janssen and Lockyer showed how the spectra of prominences could be observed without an eclipse. They argued that if the continuous spectrum of the sun were weakened by high dispersion, the spectrum of the prominences which is concentrated in a few bright lines would be visible. Soon afterwards it was found that by widening the slit slightly the forms of the prominences could be seen in monochromatic light.

By bringing different parts of the sun's limb tangential with the slit of a spectroscope, the existence of a layer all round the sun of the same constitution as the prominences was discovered. To this the name of *chromosphere* has been given. Although this can be studied at all times, the movements near the beginning and end of an eclipse are most favourable. It is found that the spectrum of the chromosphere is not the solar spectrum with bright lines in place of absorption lines, but differs in important particulars: the presence of lines due to helium, the long series of hydrogen lines in the ultra-violet part of the spectrum; and that the spectra of the metallic lines resemble that given by the electric spark, while the solar spectrum corresponds more nearly to that of the arc. The regular examination of prominences shows that they are of two kinds—quiescent and eruptive. The former are generally found on the sun's limb, and are taken out of sight by the sun's rotation. The latter shoot up with amazing rapidity, sometimes moving hundreds of miles in a second. Quiescent prominences are usually found in the polar regions of the sun; while eruptive ones are found in the spot zones, and vary in their numbers periodically with the spots.

The *corona* is of an entirely different character from the prominences. The instant an eclipse becomes total it is seen as an aureole surrounding the eclipsed sun. It is of pearly-white colour, and is brightest near the moon's dark limb. It is of complex form, and streamers from it can sometimes be seen extending to a distance of several diameters from the sun. The corona shows a faint, continuous spectrum such as would be given by incandescent solids or liquids, and in addition a number of bright lines due to incandescent gas. The continuous spectrum may indicate that part of the light from the corona is reflected sunlight, but the existence of Fraunhofer lines in it has not been certainly established. None of the bright lines have been

Fig. 2.—Sun-spot, 13th August 1911.

identified in the spectra of terrestrial elements, and they are attributed to a hypothetical gas—*coronium*. The corona is of different shape in different parts of the sun-spot cycle. At sun-spot minimum the

taken in the light of K—a line in the violet due to calcium vapour. It is found that the sun, especially in the neighbourhood of spots, is covered with white patches, called *floculi* (fleeces) from their appearance, due to clouds of calcium vapour.

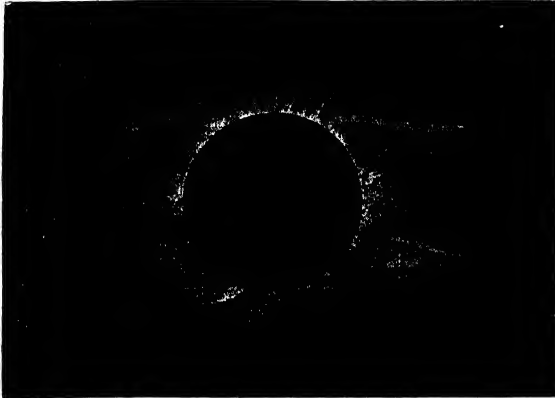

Fig. 3.—The Sun's Corona on 18th May 1901, drawn by Mr H. Morgan from Photographs taken at the Eclipse by the Expedition from the U.S. Naval Observatory.

extension is greatest in the direction of the sun's equator, while at maximum it extends irregularly from all points of the sun's disk.

The photography of the prominences was accomplished by Hale and Deslandres. They devised an instrument known as a spectroheliograph. In this instrument light falls on a slit and a spectrum is formed. All the light of the spectrum is cut out, except a very small amount, by a second slit; thus, for example, all the light except that corresponding to the red line of Hydrogen (H α) is cut out. If

Fig. 4.—Calcium flocculi.

now the whole apparatus is moved parallel to itself different parts of the sun are successively seen in the light of wave-length peculiar to H α , and when the movement is perfected photographs may be taken in light of this wave-length. Not only the prominences round the edge of the disk, but the surface of the sun, may be photographed in this way. Special interest attaches to photographs

The structure of the sun is thus seen to be extremely complicated. The lowest part emits a continuous spectrum; this passes through an absorbing layer where the dark Fraunhofer lines have their origin. Next there is a dusky layer which cuts off a great deal of the light, especially that of short wave-length, the existence of this layer being shown by the diminishing brightness of the sun as the edge is approached. Above these are the flocculi, or clouds of calcium. Then we reach the chromosphere, with its bright line-spectrum, and outside this the corona. In addition there are the more local phenomena of spots, faculae, and prominences.

(6) The rotation of the sun was discovered by Galileo from the motion of spots across the disk. The axis of the sun is fixed in direction, and inclined at an angle of 7° to the perpendicular to the ecliptic. From June 3 to Dec. 5 the plane of the ecliptic is north of the sun's equator, and the north pole of the sun is on the visible side of the sun, the south pole being visible the other half of the year.

The position of the sun's axis was fixed with precision by Carrington from a study of sun-spots between 1853 and 1861. He also made a very careful study of the rotation of the sun. The sun does not rotate like a solid body. At the equator a complete revolution takes place in twenty-four and a half days, but at 30° from the equator in twenty-six and a half days. The paucity of spots in high latitudes makes it impossible to determine the period of rotation for all latitudes of the sun by the movements of spots. In 1891 Diner determined spectroscopically the law of rotation for all latitudes to within 15° of the poles. Other observers have obtained very accurate results by this method, especially Adams, at the Solar Observatory at Mount Wilson in California. The rate at which the sun rotates in different solar latitudes is:

Latitude.	Time of Rotation.
0°	24·5 days.
20°	25·5 "
40°	27·5 "
60°	29·6 "
80°	30·6 "

These results, obtained spectroscopically, are confirmed by the motions of spots, faculae, and flocculi. Spectroscopic results from hydrogen lines which have their origin probably at a somewhat higher level show polar retardation of not more than half this amount. There is no wholly satisfactory explanation of this remarkable law of rotation.

These tabular data may be convenient:

Equatorial horizontal parallax	8·80".
Angular diameter	Max. 32' 36", Min. 31' 32".
Mean distance	92,000,000 miles.
Diameter	866,000 miles.
Volume	1,306,000 times that of the earth.
Mass	332,000 " "
Force of gravity at surface	27·6 " "
Density	1·41 times that of water.
Period of rotation at equator	24·5 days.
Velocity of rotation	1,285 miles per second.
Inclination of axis to plane of the ecliptic	82° 45'.
Longitude of node of equator on ecliptic (1900)	73° 40'.
Surface in square miles	2,800,000,000,000.
Energy radiated from each sq. ft. of surface	= 10,000 horse-power.

Sun-animalcules. See HELIOZOA.

Sunart, LOCH, a picturesque sea-inlet in the west of Argyllshire, winding 19½ miles eastward from the north entrance to the Sound of Mull.

Sunbirds (*Nectariniidae*), a family of Passerine birds related to the Honey-eaters (q.v.), having long, slender beaks and a protrusible and deeply cleft tongue. In general appearance and habits they resemble the Humming-birds of America, with which, however, they have no real affinity. They are birds of brilliant plumage, glittering with metallic lustre. They are confined to the hotter regions of the Old World, being particularly abundant in Africa and southern Asia and extending to North Australia, but the species commonly have a limited range. Captain Shelley in his monograph on the Sunbirds (Lond. 1876-80) subdivides the family into three sub-families, (1) *Neo-drepaninae*, (2) *Nectariniinae*, (3) *Arachnotrocininae*. They are all of small size, although none are so small as the smallest humming-birds; they rival humming-birds in brilliancy of plumage, and like them they feed on the juices of flowers, which they suck by their long bill, occasionally hovering in the air before a flower when feeding, but generally hopping about or clinging to the smaller twigs and flowering branches; small insects and their larvae and spiders are, however, their principal food. Some of the nectar-sucking species pollinate the flowers they visit. They have a feeble chirping note.

Sun-bittern (*Eurypyga helias*), so called from the brilliant many-coloured markings on its plumage, a South American bird about the size of a small curlew, long-legged and long-necked, which usually struts in a solemn balanced manner, but at times goes through a series of poses somewhat like the Argus (q.v.). It is found from Brazil north-west into Central America.

Sunbury, capital of Northumberland county, Pennsylvania, on the Susquehanna River (here, a mile below the junction of its branches, crossed by a bridge), 53 miles by rail N. of Harrisburg. It contains flour-mills, dye-works, foundries, and other works. Pop. (1920) 15,721.

Sun-cracks, superficial markings frequently seen on the surfaces of thin bedded flagstones and argillaceous sandstones. They are believed to have been formed in the same way as the fissures which are produced upon the mud-flats of tidal rivers or estuaries by the drying and shrinking of the deposits during their temporary exposure at low tide. The cracks are of course filled up by new deposits when the mud-flats are again overflowed. Not infrequently the material filling the sun-cracks is of harder consistency than the rock in which they occur. When the bed overlying the cracks is removed a cast of these often projects from its under surface, or frequently the casts remain in the moulds so as to form a series of polygonal ridges ramifying over the whole surface of the exposed stratum.

Sun-cult. There is no reason to believe that men have worshipped the sun itself on a wide scale. The worship of the disc of the sun, instituted by Akhenaton of the eighteenth dynasty of Egypt, is practically the only instance of the sort.

Wherever found, with this exception, the cult is not that of the sun, but of a sun-god. This cult is invariably carried on by men calling themselves Children of the Sun, who can be traced in all parts of the world. In most places they have vanished, but they still persist in Japan, the emperors of which are descended from Amaterasu, in this case a sun-goddess. The royal family of Egypt after the beginning of the fifth dynasty, the most important ruling families of India, including the family of Buddha, the Incas of Peru, and many others, were of solar descent. The sun-cult evidently originated in Egypt at Heliopolis, which is assumed to be the home of the Sothic calendar. Prior to the fifth dynasty there are but few signs in Egypt of a solar cult; but the kings of the fifth and succeeding dynasties were the Children of the Sun, having Re, the sun-god of Heliopolis, as their actual father. This family of Children of the Sun eventually, it would seem, spread throughout a large part of the world, and everywhere claimed that they were born of the union of the sun-god and a woman, often a virgin. The marriage of brother and sister, or of mother and son, was a common characteristic of this family wherever they went. The ritual of the sun-cult was, in Egypt, based on that of Osiris, the first king who was mummified. The sun-god was supposed to die every night, and every morning the king, his son, had to perform the necessary rites to bring him to life again.

Sunda Islands, a name that bears in geography two interpretations. (1) It is applied, but not very correctly, to the long chain of islands which stretches from the Malay Peninsula south-east to the north coast of Australia, beginning with Sumatra and ending with Timor. (2) In the more proper sense of the term it means the islands that lie between the east end of Java and the north side of Timor, namely Bali, Lombok, Sumbawa, Flores, Sandalwood Island, and some smaller ones. These have been already treated of in separate articles.

Sunda Strait is a passage, from 70 to 90 miles in breadth, lying between Sumatra and Java and connecting the Indian Ocean with the Sunda Sea. Several islands stud its waters, as Krakatao (q.v.), Princes Island, Steers, and Calneijer.

Sundarbans, or SUNDERBUNDS, the lower portion of the delta of the Ganges in British India, extending from the mouth of the Hugli on the west to the mouth of the Meghna on the east, a distance of 165 miles, and stretching inland for half that distance. The total area is estimated at 7550 sq. m. The region is entirely alluvial, is intersected by a network of anastomosing streams, and contains a vast number of swamps and morasses. Next the sea is a wide belt of dense jungle and underwood, the haunt of the tiger, leopard, rhinoceros, buffalo, wild hog, deer, monkeys, python, cobra, and numerous sea-birds and birds of prey. Behind this belt the land is cultivated, the fields being enclosed with embankments. Rice is the staple crop, though the people also grow pulses, vegetables, jute, and sugar-cane. Besides rice the principal products of the region are timber and fish. There are no villages, the population being thin and scattered. The chief highways are the water-courses, shown in the map at CALCUTTA. Part of the area is liable to be swept by destructive 'typhoon waves' or high tides caused by cyclones.

Sunday. See SABBATH.

Sunday-schools, as we know them in modern times, sprang from the efforts begun in 1780

by Robert Raikes (q.v.), a printer in Gloucester. Although systematic and wide-spread attention to the religious training of children is of modern date, still some attention was bestowed upon it in early times. The father acted as teacher and priest towards the children in patriarchal times; there was provision for the training of children in the knowledge of the law in the Jewish economy. Ezra read and had the law explained 'before the congregation both of men and women and all that could hear with understanding' (Neh. viii.). There were religious schools in connection with the synagogues in New Testament times. The Mishna says, at five years of age 'let children begin the Scriptures, at ten the Mishna, and at thirteen let them be subjects of the Law.' In the apostolic age teachers were set over the young and ignorant. Mosheim says 'the Christians took all possible care to accustom their children to the study of the Scriptures, and to instruct them in the doctrines of their holy religion.' Clement of Alexandria and Origen did duty as catechists. The classes of Catechumens (q.v.) were intended for the instruction of candidates for church fellowship; instruction was given on Sundays just previous to public worship, and the scholars were mostly adults. At the Reformation Luther (1529), finding the people fearfully ignorant, opened schools for children for catechising. Knox (1560) did the same in Scotland. St Charles Borromeo (q.v.), Archbishop of Milan, founded Sunday-schools in his diocese, which still exist, but these were chiefly secular. Sunday-schools are noticed in an ordinance of Albert and Isabel in 1608 as then existing in the Catholic Netherlands. The magistrates were enjoined to see to their establishment and support in all places where not already set afoot. Both Richard Baxter and the Rev. Joseph Alleine (1634-68) were in the habit of gathering young people together for instruction; and there were many irregular and isolated attempts in the same direction in different parts of Britain. But it was Raikes who founded and consolidated the modern Sunday-school system and gave the subject publicity through his journal and other organs of public opinion. There is no doubt that his philanthropic work in Gloucester gaols had impressed him with the direct connection between ignorance and crime. One day, in 1780, he had gone to hire a gardener in a low suburb of the town near the Severn, where the people were mostly employed in a pin-factory. He was grieved at seeing the groups of wretched ragged children at play in the streets, and on inquiry was informed that on Sunday 'the street was filled with a multitude of wretches, who, having no employment on that day, spent their time in noise and riot, playing at chuck, and cursing and swearing in a manner so horrid as to convey to a serious mind an idea of hell rather than any other place.' To check this he engaged four women, who kept dame-schools, to instruct as many children as he should send them on Sunday in reading and the church catechism, for which they were to receive one shilling each for their day's service. In this work he was assisted by the Rev. Thomas Stock, of St John's parish. The children gathered into the first Sunday-schools

girls were separately taught, and once a month they were publicly catechised in church as to their religious knowledge. In a short period a visible improvement was effected in both the manners and morals of the children. One employer of labour said 'the change could not have been more extraordinary had they been transformed from the shape of wolves and tigers to that of men.' More than three years after its foundation the scheme was noticed in Raikes's *Gloucester Journal* (November 3, 1783); but it was a letter by Raikes, quoted in the *Gentleman's Magazine* in 1784, which first drew general attention to the subject. In 1784 the first Sunday-school was established in London by the Rev. Rowland Hill. Numerous schools sprang up in all the principal towns, and a society under high patronage was formed in London in 1785 for the establishment and support of Sunday-schools throughout the kingdom, which in fourteen years spent £4000 in payment of teachers. By 1789 there were already 300,000 scholars throughout the kingdom. Hannah More (q.v.) started a school in 1789, and Sydney Smith one at Netheravon. Adam Smith wrote that 'no plan has promised to effect a change of manners with equal ease and simplicity since the days of the apostles;' and Cowper and John Wesley likewise approved of the system.

One great impediment to the early prosperity of the Sunday-school was the expense of hiring so many teachers. But several young men banded themselves together to teach the children gratuitously: the example spread, and soon the teaching was almost universally gratuitous. One authority says gratis teaching began at Oldham. A higher class of teachers offered their services; the schools ceased to be filled by the very poorest alone; handsome buildings were erected in connection with the different churches and chapels, or by general subscription, and that system was organised which covered the land with schools. The secular teaching, which in certain instances included writing and arithmetic, was not of a very high order; but it placed the key of knowledge in the hands of multitudes who would otherwise have been unable to read.

The establishment of The Sunday-school Union in 1803 gave a powerful impetus to the extension of Sunday schools in England. In increased attention paid to the training of teachers, grading of the classes, and the provision of schemes of lessons suitable to the various stages of the scholars' mental growth, much valuable pioneer work was done by Mr G. Hamilton Archibald and others.

Sunday-schools were introduced into Wales in 1789 by the Rev. Thomas Charles of Bala (one of the founders of the Bible Society, q.v.), and were much appreciated even by adults—in one class at Banzor every pupil wore spectacles. The Sunday-school was known in Scotland in 1756, but it was not till 1786, when the Society for Promoting Religious Knowledge was formed, that it was publicly recognised, nor till 1795, when the Gratis Sunday-school Society was originated, that schools became general. At first they met with considerable opposition from both the civil and ecclesiastical authorities. The names of Dr Chalmers, James Gall, and David Stowe deserve mention in connection with the progress of Sunday-schools in Scotland. In Ireland Sunday-schools had been partially anticipated by Dr Kennedy, in County Down, in 1770; but it was not till 1785 that the system pursued by Raikes was adopted. The Sunday-school Society for Ireland was established in 1809.

In the United States, as in Great Britain, there were isolated attempts at Sunday-school teaching before the example of Raikes reduced it to a system. The Methodist Bishop Ashbury (q.v.) is said to have planted the first American Sunday-

one required, both children, and even men, women, and their hair combed.' Owing to the total ignorance of the scholars the teaching was of an educational nature at first; the little folks learned their letters, and to spell and read. The schools opened at 8 A.M., by 8.30 lessons were begun; afterwards the children went home, or to forenoon service, and in the afternoon to school again at the close of the church service till 5.30 P.M. Boys and

school in Hanover county, Virginia, in 1786. The Methodist Conference in 1790 resolved to establish Sunday-schools for white and black children. A Sunday-school Union was formed at Philadelphia in 1791 which employed paid teachers; the New York Union was formed in 1816; and the American Sunday-school Union in 1824, which sprang from the Sunday and Adult School Union (1817). The Congregationalists, Methodist Episcopalians, Presbyterians, and Baptists have also organisations. Dr Vincent, one of the founders of Chautauqua (q.v.), and Mr Jacobs originated the International Series of Lessons (1873). The Sunday-school is an invariable adjunct to the work of the missionary. Roman Catholics have also Sunday-schools.

H. Archibald, *The Organisation and Grading of a Sunday-school* (1904), *The Junior Department* (1907), *The Sunday-school of To-morrow* (1909), and *The Modern Sunday-school* (1926); E. Archibald Johnston, *The Primary Department* (1924).

Sunday Society, an institution founded in 1875 'to maintain and enhance the importance of the English Sunday,' included amongst its members Dean Stanley, Huxley, and Tyndall, and addressed itself zealously to secure and maintain the opening of museums and galleries on Sundays. It was in direct response to an appeal by the society that in 1908 the National Gallery and the Wallace Collection were opened on Sundays throughout the year. Others followed. The Sunday National League, aiming to promote intellectual and elevating recreation on Sundays, had been established as early as 1855. A Sunday Lecture Society was founded in 1869, and succeeded in proving that its lectures (by Huxley, Carpenter, and others), together with sacred music, were not an infraction of the Sunday Act.

Sunderland, a seaport, municipal, county and parliamentary borough of Durham, situated at the mouth of the Wear, 13 miles N.E. of the city of Durham, and 12 SE of Newcastle-upon-Tyne. A monastery was founded by Benedict Biscop (q.v.) on the north side of the river in 674. Bede, who was a member of this establishment, called the river the Wiri. Towards the close of the 12th century Wearmouth became a borough, but until the discovery of coal in the district it does not appear to have been a place of much importance. It was in 1396 that the first exportation of coal from Sunderland took place, while the first mention of shipbuilding on the Wear occurs in 1346. The borough received its charter of incorporation from Bishop Morton in 1634. It was about 1669 that letters patent were granted for the building of a pier and lighthouse, the harbour at that time being almost un navigable. There was no bridge over the Wear at Sunderland until 1796, when Rowland Burdon, M.P., advanced a large sum towards that object, and an iron structure with a span of 236 feet was thrown across the river. The bridge was remodelled, widened, and improved in 1859 by Robert Stephenson. In 1839 the North Dock was opened, and in 1860 the South Dock, while in 1880 a lock was constructed to connect the docks with the south outlet.

Sunderland is an extremely progressive commercial centre. Its geographical position in the midst of the coal and metalliferous-ore area, and its proximity to sea, river, and railway communication have secured for it immense advantages. From the harbour entrance, by means of the north half-tide basin, vessels have direct passage into the docks. Concrete piers, faced with granite, afford adequate protection to the harbour entrance. A

water area of 211 acres is covered by the harbour entrance, the south outlet, and the docks. There are seven graving docks, a huge pontoon—capable of lifting 7000-ton vessels—and warehouses, store-houses, cranes, &c., elaborately fitted for the handling of goods; especially noteworthy are the arrangements for the shipment of coal. Steam-trawlers and other fishing-vessels land cargoes near the entrance to the river at the Fish Quay, in direct railway communication with all parts of the country. Shipbuilding on Wearside has long been famous, all kinds of vessels up to 15,000 tons gross being turned out; there are excellent facilities for repairs, refits, &c., as well as good engineering works for every type of engine. Besides the yards supplying ship fittings, there are foundries, breweries, collieries, potteries, and brass, iron, glass, paper, chemical, and electrical works.

As a town, Sunderland is well laid out. The more important buildings include the Theatre Royal (1853); Workmen's Hall (1872); Public Library, Museum, and Art Gallery (1879); Town Hall (1890); Technical College (1901); Quarter Sessions and Police Court Buildings (1907); Queen Alexandra Rail and Road Bridge between Deptford and Southwick (1909); and the Training College (1922). Of the many churches in the borough, the most interesting is that of St Peter, Monkwearmouth; remnants of the original church (674) are retained in parts of the western tower and western wall of the nave; while there are fine stained-glass windows, also some good carving. Sunderland is a healthy town, owing to its proximity to the North Sea. It possesses no less than seven public parks, with the usual recreations; Barnes Park has an area of 33 acres. Roker, Sunderland's seaside suburb, is situated on the north side of the river about a mile from the centre of the town. The bathing is good, the beach being protected with piers, and there are parks, promenades, &c. Sunderland returns two members to parliament. Pop. of parliamentary borough (1851) 67,394; (1881) 124,760; (1901) 159,359; (1921) 173,742, of whom 159,100 were in the municipal and county borough. Havelock was born at Ford Hall, Bishopwearmouth (1795); Jack Crawford, the hero of Camperdown (1775-1831), at Sunderland; and other natives were Clarkson Stanfield, R.A., Tom Taylor, Sir Joseph Wilson, and Swan the electrician.

Sunderland, ROBERT SPENCER, EARL OF, was born in 1640, and in September 1643 succeeded his father, who fell at the first battle of Newbury, having three months before been created first earl. After serving as ambassador to several courts, in 1679 he became Secretary of State, and at first united with Essex and Halifax in opposing Shaftesbury, who wished to set Monmouth on the throne, and favoured the exclusion of the Duke of York. He encouraged Charles II. to persevere in the degrading French alliance, and, with the Duchess of Portsmouth, to whom he attached himself, negotiated a treaty by which, in consideration of an annual French pension, Charles was to assemble no parliament for three years. Before the year was out a new triumvirate, consisting of himself, Hyde, and Godolphin, succeeded to the confidence of Charles. The treaty with France was broken off, and Sunderland, who was now afraid of the Whigs, engaged the king in a more popular alliance with Spain. After the dissolution of the last of the exclusion parliaments he lost his office; but the duchess remained faithful to him in disgrace, and in 1682 he was, 'upon great submission made to the Duke [of York], again restored to be Secretary.' He remained in office until the accession of James II., when his influence in the ministry became greater than ever. Although there is reason to believe he gave some encouragement to Monmouth

in his rebellion, he managed, with consummate art, to win James's entire confidence, and in 1685 became prime-minister. He alone was entrusted with a knowledge of the king's intention to establish Catholicism as the national church; and in 1687 he privately conformed thereto, and afterwards openly professed his conversion. His influence was so great that James would grant no favour until he had asked the question: 'Have they spoken to Sunderland?' and when told that this nobleman got all the money of the court, he would reply: 'He deserves it.' Yet we find him about this time in correspondence with William of Orange. With profligate but masterly dexterity he contrived to deceive both James and Barillon, and to keep them in ignorance of the events that were passing in Holland. When William arrived in England Sunderland went to Amsterdam, whence he wrote to the new monarch, claiming his favour and protection on the ground that he had all along been in his interest. In 1691 he was allowed to return to England, and to kiss the king's hand; in 1695 William spent a week at his house at Althorp. He had changed, it was said, his religion, in the late reign, in order the more effectually to ruin King James; and it was generally believed that he had rendered King William, when Prince of Orange, some signal services, which no one else could have done. This belief gained credit from the favour now shown him. He was made Lord Chamberlain, and as such took his seat at the head of the council table. After directing affairs as the acknowledged head of the government, he resigned office in 1697, and retired to Althorp, where he died, 28th September 1702. By his wife, Anne, daughter of the second Earl of Bristol, he left CHARLES SPENCER, third earl, who was born in 1675, and whom Evelyn describes as a youth of extraordinary hopes, very learned for his age, and ingenious. From 1706 to 1710 he was Secretary of State in the reign of Queen Anne, and under George I. he rose to be all-powerful; but in 1721, being accused of receiving £50,000 worth of the fictitious stock distributed by the directors of the South Sea Scheme (q.v.), in order to bribe the government, he was acquitted only by an inconsiderable majority and that from party considerations, and the indignation of the public made him resign his office. He died on 19th April 1722, not without suspicion of having intrigued, after his fall, for the restoration of the Tories, if not for the return of the Pretender. Sunderland was a type of the political morality, or rather immorality, of a disgraceful age, when the greatest statesmen made no scruple of sacrificing either their own party or the interests and dignity of the nation to personal ambition. His title descended to Charles, his second son, who succeeding in 1733 to the honours of his maternal grandfather, John Churchill, the earldom of Sunderland became absorbed in the dukedom of Marlborough. The third son, John, was father of the first Earl Spencer (q.v.).

Sundew. See INSECTIVOROUS PLANTS.

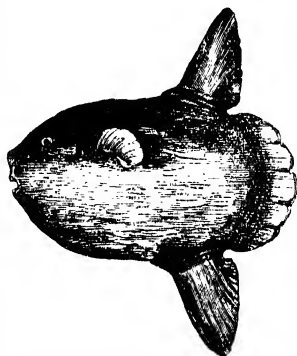

Sun-dial. See DIAL.

Sundsvall, a seaport of Sweden, on a bay of the Gulf of Bothnia, 80 miles N. by W. of Stockholm, and 290 miles by rail E. by S. from Trondhjem in Norway, has ironworks and saw-mills, and a large trade in iron and timber. Pop. 17,000. The town was almost entirely destroyed by fire in 1888.

Sunfish (*Molidae*), a family of Teleostean fishes in the sub-order Plectognathi, nearly related to 'Globe-fishes' (*Tetrodontidae*) and 'porcupine-fishes' (*Diodontidae*). Two genera, *Orthogoriscus* (or *Mola*) and *Ranzania*, are distinguished; both are

occasionally represented off British coasts. The body, unlike that of globe-fishes and porcupine-fishes, is non-inflatable; it is laterally compressed, truncate posteriorly, without a caudal fin; the dorsal and ventral fins are strongly developed and pointed; the skin is rough or tessellated; the very young stages (formerly referred to a distinct genus, *Molacanthus*) are armed with spines. The Sunfishes have a wide distribution, occurring usually near the surface in the open sea, but sometimes descending to great depths. One of the best known forms is the cosmopolitan Short or Rough Sunfish,

Orthogoriscus mola, often found on the south coasts of England and Ireland. It may attain a length of 8 feet and a weight of 1800 pounds. In the young the vertical axis is as high as the longitudinal axis is long, but in the adults the latter increases a little in proportion. The spinal cord is only about as long as the brain, if the slender filum terminale is not counted in. There are only 17 vertebrae. The fish sometimes swims about in a leisurely way near the surface, with its high dorsal fin projecting out of the water; and to this habit of sunning itself, if not to the somewhat circular shape, the name Sunfish may refer. The food seems to consist of larval fishes, pelagic crustaceans, jelly-fishes, and the like; and it is an interesting fact that the very young *Lepidosteus* stages of the common eel are found in the Mediterranean in the stomach of Sun-fish. The flesh is white and well-flavoured, somewhat resembling that of the skate. There is much oil in the liver, and this is in repute among sailors as an external application for the cure of sprains and rheumatism. For another Sun-fish, see OPAH; and for another (the basking-shark), see SHARK.

Short Sunfish (*Orthogoriscus mola*).

Sunflower (*Helianthus*), a genus of Compositae, having large flowers; the florets of the ray strap-shaped, without stamens or pistils, yellow or orange; the florets of the disk tubular, perfect, yellow or purplish brown; the heads solitary or in corymbs, with an involucre of numerous leaves; the fruit compressed, with a pappus of two or more deciduous scales. The species are numerous, all natives of America; large herbaceous plants, with opposite or sometimes alternate undivided leaves. The Annual Sunflower (*H. annuus*), common in flower-gardens, is a native of tropical America, where it sometimes attains a height of 20 feet. The stem is thick and rough; the heads solitary, and from 1 foot to 2 feet in diameter, nodding; the leaves heart-shaped-ovate. This plant is now cultivated in almost all parts of the world, and in south-eastern and central Europe is a field-crop, the seeds being valued as food for cattle, cage-birds, and poultry, and for their oil, little inferior to olive-oil, and the residual cake (a cattle-food). An acre of good land produces about fifty bushels of seed, each bushel yielding a gallon of oil. The seeds are also used like almonds for making demulcent and

soothing emulsions; and in some parts of Europe a bouilli is made of them which is used as food for infants.

Sunflower
(*Helianthus annuus*,
var. *multiflorus*).

Russians eat them like nuts, and American Indians make bread of them. The flowers abound in honey, and are much frequented by bees. The leaves are good fodder for cattle. The stems and husks are used for fuel, and yield much potash. A profusely flowering garden variety, *H. multiflorus*, is referred to the same species. The error that the flowers turn with the sun is mentioned by Gerarde (1597), who adds, 'the which I could never observe, although I have endeavored to finde out the truth of it.'—The Jerusalem Artichoke (q.v.) is of this genus.

Sungei Ujong, a native state of the Malay Peninsula under British protection, with which Jelebu was united in 1888. In 1895 Sungei Ujong rejoined the confederation known as Negri Sembilan ('Nine States'), to which it had once belonged, comprising Sri Menanti, Johol, Rembau, and Tampin; and in 1896 Negri Sembilan became one of the Federated Malay States.

Sunnim. See COLONNA.

Sunn. See CROTALARIA, FIBROUS SUBSTANCES.

Sunnites, the name commonly given to orthodox Muslims, because in their rule of faith and manners the Sunna (pron. *Soomna*), or traditional teaching of the Prophet, is added to the Koran. According to Islam the human mind is incapable of attaining light in law or religion but through the Prophet, and all expressions of God's will are equally important. Reason and conscience are here of no value; memory is all. Hell-fire is the award due alike to him that prays without being properly washed and to him that denies the word of the Prophet. Accordingly during the Prophet's life his counsel was eagerly and continually sought; and after his death his example and sayings were collected as of infinite value. After the death of the four rightly guided khalifs, Abu Bekr, Umar, Othman, and Ali, intimate friends of the Prophet, fearful uncertainty arose and gradually occasioned the four schools of the four orthodox Imams. The first of these was Abu Hanifa, born in Basra of a noble Persian family. He taught in Kufa on the Euphrates. He logically deduced from the Koran all religion and law; for the Koran says (Sura 16: 91) 'to thee we have sent down the book which clears up everything.' Consequently, when the Koran says (S. 2: 20) 'for you have I created the whole earth,' it follows that to Muslims belongs all the property of unbelievers. Hence the propriety of piracy and aggressive war against them. In his school arose the famous legists of Iraq, and his system, the most widely spread of the four, now prevails in the Turkish territories. He would never hold any office under government, fearing the doom due according to prophetic tradition to every giver of a wrong decision, namely, to be plunged into hell from a height of forty days' journey. He died in 767 in prison, where the khalif had confined

him for refusing to be Cadi over the new capital Bagdad.

In 795 died Malik ibn Anas in his eighty-fourth year at Medina, where he was born and had lived all his days. There, surrounded by traditions of the Prophet, he had taught after the custom of Medina. This had been impossible to Abu Hanifa, residing amid a partly foreign people and a very complex civilisation. Malik gathered from the Koran and from local traditions of Mohammed his *Muwettaa*, or Beaten Path, a complete body of law and religion. He never announced any such tradition without a previous ablution. On his death-bed he regretted with tears that he had ever used his own judgment in pronouncing an opinion on a point of law, and wished that he had been flogged and reflogged every time. His system was established in North Africa by African students, who found Medina the most convenient school, and in Spain by his Berber pupil Yahya 'bn Yahya. The third orthodox imam was Ash-Shafi'i of the Korashi tribe, and descended from the Prophet's grandfather, Abdul-Muttalib. He was born, it is said, on the day of Abu Hanifa's death. He taught in Cairo, and there he died in 820. He was an eclectic, but leaned more to the traditional precedents of his teacher Malik than to the deductive method of Abu Hanifa. His system prevailed in Egypt, and was not uncommon eastward. It still flourishes in the Asiatic islands.

The use of reason and Greek philosophy had by this time wrought such laxity in faith and in public and private conduct that rigid puritanism was a natural concomitant. Its exponent was Ibn Hanbal, the fourth orthodox imam, who died in 855 in his native city Bagdad, beyond which his system never had much power. He was a pupil of Ash-Shafi'i, whose lectures, however, he would never allow his own pupils to attend. Tradition and Sunna had now immensely increased, and by these alone the Hanbalites were guided. They are now almost extinct, but were strenuous in their early days, when they would break into festive meetings in Bagdad, beat the singers, break the musical instruments, and pour the wine into the streets. The bulk of tradition had now made editing indispensable, and those huge masses of it began to appear under which the Muslim mind has been crushed to death. As Ibn Hanbal said, 'the punishment of the learned man in this world is blindness of heart.' Abu Hanifa had used only 18 traditions, Malik 300. Ibn Hanbal used 30,000. These were mainly collected by his friends and pupils. One of these, the excellent Abu Da'ud Iuleiman, travelling in many Muslim lands, collected half a million, which he sifted down to 4800. Another, Yahya 'bn Main, spent a large fortune and wore out his last pair of shoes in collecting 600,000. Helpers copied as many more for him. 'I copied quantities of traditions to the dictation of liars,' he said, 'and heated my oven with them, whereby my bread was well baked.' But of the six accepted collections the standard one was made by Al Bukhari, a friend and pupil of Ibn Main. He taught in Bagdad, and like the best Muslim theologians was a Persian. He died in 870. Of the 600,000 traditions heard by him he admitted only 7275, whereof the half are probably genuine. Till he had washed and performed two rekas of prayer he never inserted any tradition. An edition by Krehl appeared at Leyden in 1862-72, in 3 vols. The collection by his Muslim pupil is better arranged, and is more used. The sources of tradition were Ayesha, the first four khalifs, and the six companions of the Prophet, of whom Abu Horaira, a manifest liar, was more prolific than any other. Through one of these channels to Mohammed the *isnad* or pedigree of every tradition

had to be traceable. Worth or internal evidence counted for nothing. The work of collecting was begun too late. The real origin of most traditions was the requirements of interested parties, conscious mendacity, or gossip, specially in the standing camps of Arabs required in every conquered land. The matter is called Hadith, events, tradition, and is much more entertaining than the Koran. Besides the legal and religious utterances of Mohammed, which are generally in one or two sentences, it embodies endless nonsense about his life and miracles, although Mohammed disowned all miracles but his own inspiration, about spirits, the beginning of the world and its end. Whatever in the Hadith can be imitated or obeyed is Sunna, method; compulsory for guidance if connected with religion, but redundant or collateral, though praiseworthy, if giving mere details of such things as the Prophet's mode of standing and sitting. Its object is to make needless all appeals to reason and conscience. In legislation it is much less used than formerly; but, like the Koran, it is infallible and unalterable, and its only independent expounders are the four orthodox imams. Legislation merely means a declaration by the Sheikh-ul-Islam and his council of ulema or doctors that this or that agrees with the Koran or tradition. Reformation of law or religion from within is impossible.

Sunstroke (otherwise called Heatstroke, Heat Apoplexy, Heat Asphyxia, Coup de Soleil, Erythimus tropicus, and Insolation) is a very fatal affection of the nervous system, which seldom occurs in Great Britain, except in extremely hot summers, but is very common in India and other tropical countries. The symptoms of the disease are liable to be greatly modified in different cases. Two contrasted forms are recognised. In the *cardiac* the heart is chiefly affected, and the symptoms are weakness, faintness, dimness of sight, giddiness, &c. Death may take place either suddenly or more gradually from failure of the circulation. If recovery occur it is complete. This form may be caused by the sun's rays (sun-stroke), or may occur in close hot places (heat stroke). In the *cerebro spinal* form, or *seriasis*, the symptoms usually come on more gradually; nausea and giddiness may be present at first; but the most striking feature of the disease is deep unconsciousness or coma, with a pungently hot skin and extremely high temperature—106° F. or upwards. Even those who recover from this form of the disease are apt to suffer for a long period, or it may be permanently, from severe headache, epilepsy, enfeebled mental power, or other nervous disorders. Intermediate varieties are also met with, forming links between these two extremes. The mortality from sunstroke is about one in four of those affected. In the cases that terminate favourably a gradual remission of the symptoms takes place; and when the skin becomes cool and moist, and sleep has been procured (phenomena which usually occur within thirty-six hours of the attack), the patient may be regarded as out of danger.

The predisposing causes of sunstroke are (1) an unusually elevated degree of temperature; (2) heavy or nudely tight clothing, particularly if it interfere with the free expansion of the chest; (3) a contaminated atmosphere from overcrowding; (4) all debilitating causes, such as prolonged marches, previous disease, intemperate habits, &c. Death sometimes occurs so suddenly that there is little opportunity for treatment, but the general indications in these cases are the cold douche, from a height of three or four feet, keeping the surface wet and exposed to a current of air, the exclusion of light as far as possible, and the free employment of stimulants. In less rapidly fatal cases the outer clothing should be removed, and the douche

applied, as before, over the head and along the spine. Relaxation of the pupil is the first favourable sign. In the cardiac form, where the seizure is of the nature of a severe faint or syncope, and also in the cerebro-spinal form if the pulse flags, the douche must be replaced by the mere application of cold to the head, and it may be necessary to apply hot bottles, &c., to the extremities. The extremities and chest should be stimulated with mustard poultices. If the breathing threatens to fail, recourse should be had to artificial respiration. If injurious effects persist long after partial recovery, the patient should be removed to a cooler climate.

Sun-Yat-Sen, son of a Cantonese Christian convert, born in 1867, studied medicine for five years at Hong-kong, promoted an unsuccessful rising at Canton in 1895, and fled to Japan and the United States. He was kidnapped a month after reaching London at the Chinese Legation, and freed only on the intervention of Lord Salisbury (1896). He was in China preaching reform during the Boxer troubles; returned to America and Europe to collect money from his countrymen abroad; and, once more in China, became the soul of the revolution at Hanyang (1911) which issued in the establishment of the Chinese republic, of which he was chosen provisional president. He withdrew in favour of Yuan Shih-kai; but a breach came in 1917. From 1921 Dr Sun maintained himself on the whole—though driven out for a time in 1922–23—as head of a Southern Chinese republic at Canton, and leader of the more democratic element. His influence waned however, and he died 12th March 1925. See CHINA, and a book on him by Cantlie and Jones (1912).

Suomenlinna, or SVEÅBORG, fortress of Hel-singfors (q.v.).

Suomi. See FINLAND.

Supererogation, WORKS OF (Lat. *opera supererogatoria*), a class of works which, in the Roman Catholic system, are described as not absolutely required of each individual as conditions to his eternal salvation. The doctrine is based on the distinction between *præcepta* and *consilia evangelica*, the former including the common duties of all, the latter (called also 'Counsels of Perfection') establishing a merit. Roman Catholics found this definition on the distinction between what they believe to be commanded and what they hold to be only counselled, for an example of which they appeal to the words of our Lord to the young man in Matthew, xix. 21, which distinguish one class of works which are necessary in order to 'enter into life,' and a further class which must only be done if we 'would be perfect.' Roman Catholics do not profess to recognise in works of supererogation any distinctive essential quality by which they differ, whether in their physical or their moral entity, from other works, and in virtue of which, by their own nature, the individual may found upon them a personal claim to reward. For works of supererogation, as for all supernaturally good works, they hold that the assistance of God's grace is indispensably necessary; and they do not ascribe to them any merit, except that which arises from God's own free and gratuitous promise. In one word, the only distinctive characteristic of a work of supererogation lies in its not being supposed to be prescribed or commanded as absolutely necessary for the salvation of the individual, and its being done for the sake of greater perfection; and the doctrine which teaches the possibility of such works is, according to Catholics, a necessary consequence of the unequal fervour and unequal degree of holiness which exist even in the class of the virtuous servants of God. The main difficulty

comes in at the next step—the claim that a further consequence of this doctrine is that God may accept the superabundant works of one in atonement for the defective service of another. Hence in the theory of indulgences, along with what they regard as the infinite and inexhaustible treasure of the merits of our Lord, Roman Catholics also regard, although in a degree infinitely inferior, the superabundant merits of the saints as forming part of that ‘treasure of the church’ which is applied in the form of indulgences. See INDULGENCE.

Superfotation, or the circumstance of two distinct conceptions occurring in the same woman at a considerable interval, so that two fetuses of different ages—the offspring possibly of different fathers—may co-exist in the uterus, is a subject of great interest both in a scientific and in a medico-legal point of view. Two centuries ago there was a universal belief in not only the possibility but the comparative frequency of this occurrence. Early in the 19th century it was as universally disbelieved; and now again (owing to the investigations of various inquirers) we are returning to the belief of our ancestors. The cases described as instances of superfotation may be arranged in three classes; but it is only to the cases of the third class that the term superfotation is truly applicable. The first class includes the numerous undisputed cases in which two mature children, bearing evidence, from their different colours, that they are the offspring of different parents, are born at the same time. (In the slave states of America it was by no means uncommon for a black woman to bear at the same time a black and a mulatto child—the former being the offspring of her black husband, and the latter of her white lover; and the converse has occasionally occurred—a white woman at the same time bearing a white and a mulatto child.) There is no difficulty in accounting for these cases, which may be examples of nearly contemporaneous conception rather than true superfotation. The second class includes those cases in which a twin has aborted, leaving its fellow undisturbed in the uterus, to be matured and born in due time, or in which twins have been produced at the same time, one of which was fully formed, while the other was small and apparently premature, from being ‘blighted’ or arrested in its development at an early period, or in which the birth of two children, both mature or nearly so, is separated by a short interval. Cases of these kinds are by no means rare; but there is no reason for believing that the infants were conceived at different periods.

The third class only presents serious difficulty. A case of genuine superfotation may be defined as one in which a woman bears two (or more) mature children, with an interval of weeks or months between the birth of each; or, if she part with the whole contents of the uterus at the first delivery, the difference of the ages of the fetuses, or the mature child and the fetus, as the case may be, must be unmistakable, and there must be the absence of all marks of blight of the latter, so as to leave no doubt that, had it remained in utero, it would have gone on to perfect maturity. Several apparently well-authenticated cases are on record where a second living child has been born two, three, or four months after the first; and these seem inexplicable on any hypothesis except that a second conception has taken place during the progress of the first pregnancy. Cases of double uterus occasionally occur; and in the absence of clear evidence to the contrary it is possible that a second conception may have taken place in the unoccupied division.

Superheated Steam. See STEAM, STEAM.

Superintendent is, especially in the Lutheran Church, a clergyman who exercises supervision over the clergy and churches of a district, but without claiming episcopal rank or authority. In the Reformed Church of Scotland, without infringing Presbyterian polity, there were superintendents from 1581 till the introduction of Episcopacy in 1610.

Superior. See CASUALTIES, FEU.

Superior, in Wisconsin, at the west end of Lake Superior, and opposite Duluth, ships iron and copper ore, is a great grain-market, and has ship building, flour milling, and many manufactures. Pop. (1890) 11,983; (1900) 31,091; (1920) 39,671.

Superior, LAKE, the largest body of fresh water on the globe, is the highest and most western of the great lakes lying between Canada and the United States. It is bounded on the N. and E. by Ontario, on the S. by Michigan and Wisconsin, and on the NW. by Minnesota. Greatest length, 412 miles; greatest breadth, 167 miles; area, 32,200 sq. m.—nearly that of Ireland. The surface of the lake is 601½ feet above the level of the sea, and its mean depth about 475 feet; its maximum depth is 1008 feet, or 406 feet below the level of the sea. Its surface has an elevation of 20½ feet above that of Lakes Huron and Michigan; this difference occurs in the rapids of St Mary's River, the only outlet (see SAULT STE MARIE), where the average discharge is 86,000 cubic feet per second. Lake Superior, being situated very near the watershed between Hudson Bay and the Mississippi, receives no rivers of importance, although hundreds of small rivers pour themselves into it, the largest the St Louis and the Nipigon. Its aggregate drainage area (including its own area) is 82,800 sq. m. (Compare the articles on the four other lakes of the system, and those on Victoria Nyanza, Baikal, &c.) Near Dog Lake (318 miles by rail E. of Port Arthur) a short portage connects streams flowing to Lake Superior with others flowing north to Hudson Bay. The Sault Ste Marie Canal (¾ mile, opened 1895) gives continuous navigation from the head of Lake Superior to the sea, 2384 miles.

The bold northern coast is fringed with rocky islands, some rising from deep water to 1300 ft. above the lake. The largest island is Isle Royale, which is 44 miles long. The southern shore is generally lower and more sandy, with occasional ridges of limestone. Keweenaw Point (q.v.) projects far into the lake. At Grand Isle Bay, about 100 miles W. of Sault Ste Marie, are the Pictured Rocks, cliffs of sandstone from 50 to 200 feet high, in many places presenting fantastic forms, and marked by numerous vertical bands and blotches of red and yellow. The boundary line between Canada and the United States is drawn through the centre of the lake from its outlet to the mouth of Pigeon River, but is diverted so as to include in the United States Isle Royale.

The water of Lake Superior is singularly pure and transparent. It never freezes over, but the shore ice prevents navigation in winter. The lake also is subject to very violent storms; waves have been observed, during protracted autumn gales, 15 to 18 feet high. It has the small tides common to the great lakes (see MICHIGAN), and also the swishes seen in Swiss lakes—a regular series of small waves, or pulsations, at intervals of about ten minutes.

The rocks around the lake are very ancient, belonging principally to the Laurentian and Huronian systems of the Azoic series, overlaid in some places, especially on the south side, with patches of the Lower Silurian (soft sandstones). There is everywhere much evidence of glacial action. On the north side, both on the islands and shores, copper and silver are worked, especially at Thunder

Bay; while the copper and red hematite iron ores of the south side are celebrated (see COPPER). The principal towns on the Canadian side are Sault Ste Marie and Port Arthur, and on the other side the American Sault Ste Marie, Duluth, Superior, and Marquette. The Canadian Pacific Railway skirts parts of the northern shore.

Superphosphates. See PHOSPHORUS.

Suppé, FRANZ VON (1820-95), an Austrian composer of light opera, born at Spalato in Dalmatia, who was music director in Vienna theatres.

Supple Jack, a name given in the southern United States to *Berchemia rotundifolia*, a twining shrub of the family Rhamnaceæ, which is found as far north as Virginia. It has oval leaves, small flowers, and violet coloured berries. Some of the tropical American *Paullinias* are also called Supple Jack. The same name is also given in the West Indies and tropical America to *Serjania lucida*, a shrub of the family Sapindaceæ (q.v.), with a long, flexible, woody stem, which climbs to the tops of the highest trees, and is used for walking-sticks.

Supply. See DEMAND AND SUPPLY.

Supply. COMMISSIONERS OF, so called because they were originally appointed for the purpose of levying and collecting the land tax or cess offered as 'supply' to the sovereign, were long the chief county authority in Scotland for administrative and rating purposes. They were first appointed by the Act of Convention of 1667, and in order to qualify them to act they required formerly to be possessed of £100 Scots of yearly valued rent in property, superiority, or liferent. Until 1854 they were individually named in acts of supply; but since the passing of the Valuation Act in that year they have consisted of all owners of lands and heritages (other than houses) of the annual value of £100, of owners of houses of the value of £200 a year, of the eldest sons of owners of lands of £400 annual value, and, in the absence of their constituents, of the factors of owners of £800 a year, together with the sheriff and sheriff-substitute and certain representatives of the burghs within the county. It was by them that the general business of the county used to be conducted; they executed the statutes regarding its administration and finance; under the County General Assessment Act of 1868 they raised by rate the money necessary to meet the general expenditure of the county; they prepared annually a valuation roll of all lands and heritages within the county; they appointed the county officials; and in each county, with the exception of Orkney and Shetland, they maintained a force of police. By the Local Government (Scotland) Act, 1889, all these powers and duties were transferred to and vested in the County Council. Under the Act of 1889 the Commissioners of Supply still meet annually in May on the same day as the County Council. They transact no business, however, other than electing a convener and appointing certain of their number to sit with representatives of the County Council on a standing joint committee which superintends the police and the capital expenditure of the county. For a parliamentary Committee of Supply, see PARLIAMENT.

Supporters. See HERALDRY.

Suppuration is a morbid process which gives rise to the formation of Pus (q.v.), which, as is well known, is one of the commonest products of inflammation. The fluid portion of pus is agreed by all to be derived mainly from the liquor sanguinis; but with regard to the origin of the pus-corpuscles there has been a singular fluctuation of opinion. Before 1850 it was generally held that they

developed in the fluid exudation of an inflammation by aggregation or growth of granules contained in it. This doctrine was replaced by that of Virchow (1858), who believed that they resulted from rapid multiplication of the cells of the irritated tissue. In 1867 Cohnheim, repeating accurate but neglected observations made in England more than twenty years before, showed that during inflammation (q.v.) white blood-corpuscles escape from the capillaries, and make their way through the tissues; and he maintained that these, and not fixed tissue-cells, give origin to pus-corpuscles. At present Cohnheim's view is generally regarded as the true explanation in the majority of instances; but it is maintained by some pathologists that at least in some cases many of the corpuscles arise from multiplication and alteration of the cells of the inflamed tissue, an opinion which at the present time has been found to be very largely the case.

With regard to the causes which lead to suppuration there has been almost as great a change of current opinion during the same period. It used to be regarded as the natural result of any kind of severe irritation, and a necessary incident in the healing of the great majority of wounds. But when Lister demonstrated the possibility of preventing it in many cases by Antiseptic (q.v.) methods, and when micrococci were found in the pus of many abscesses, even where there had been no visible breach of surface, it became clear that microscopic organisms play an important part in the process. The experiments of some observers indeed led them to conclude that though some of the results of inflammation may be unmanifest, suppuration cannot take place without their presence and activity. It has been shown, however, (1) that dead micro-organisms can excite suppuration; (2) that a fluid in which they have grown, even when completely freed from solid particles can do so - i.e. that their influence depends, at least in part, not on the organisms themselves, but on chemical products of their growth; (3) that certain chemical irritants (e.g. mercury, turpentine, croton-oil) experimentally introduced into the tissues of animals with the most complete antiseptic precautions do lead to suppuration. Such conditions, however, can hardly occur except as the result of a carefully planned experiment; and in cases coming under the care of the surgeon it may be assumed that where suppuration is present it is due to micro-organisms.

Suppuration must thus be regarded as one phase of that effort of the organism to resist the causes of disease which takes so prominent a place in pathology at the present day. But though essentially a defensive process, it very frequently becomes harmful, and leads to serious results. If suppuration takes place beneath a surface which does not participate in the morbid change, or which is capable of resisting it for a time, an abscess is formed; when pus-cells are poured forth from an exposed surface we have an ulcer.

See INFLAMMATION; Liver on inflammation, and Metchnikoff (1892); Walker's *Pathology of Inflammation* (1904); and treatises on pathology such as those of Barlow, Green, MacFarland, Reesman, and Adam (1901-10).

Supralapsarian. See PREDESTINATION.

Supra-renal Capsules. two small, flattened, glandular bodies of a yellowish colour, situated, as their name implies, immediately in front of the upper end of each kidney (q.v.). In weight they vary from one to two drachms. They belong to the class of ductless glands, and on making a perpendicular section each gland is seen (like the kidney) to consist of cortical and medullary substance, surrounded by a fibrous investment which is intimately connected with the subjacent structure,

and is continuous with the fibrous stroma which pervades the organ. In the cortical portion the cells are arranged in rows or columns, and are polyhedral in shape, while in the medullary portion the stroma forms a network, in the meshes of which groups of cells of more irregular outline are found. The blood-vessels and nerves of the glands are exceedingly numerous. Their function is somewhat obscure, but they produce an internal secretion—adrenalin—which is associated with the maintenance of tone in the walls of blood-vessels, and thus with their contraction and the arrest of hæmorrhage. In 1855, however, Dr Thomas Addison showed that a rare form of disease, characterised by progressive debility and emaciation, with increased pigmentation of the skin (known as *Addison's Disease*, or *Bronzed Skin*), is associated with disease of these organs. It has since been proved that only one particular form of degeneration leads to this result; cancer, sarcoma, &c., have no similar consequence.

Supremacy, ROYAL. The term supremacy is, in politics, chiefly used with regard to authority in matters ecclesiastical. From the time of Pope Gelasius (494 A.D.) to the Reformation the pope exercised a very extensive authority, judicial, legislative, and executive, over all the churches of western Europe, somewhat undefined in its limits, varying in different countries and at different periods; and this continues to be more or less recognised in all countries whose inhabitants are in communion with the Church of Rome. The Statutes of Provisors (q.v.) and Pœnninire (q.v.) asserted in some measure the authority of the sovereign; but at the English Reformation the papal supremacy was abolished, and 26 Henry VIII. chap. 1 declared the king and his successors to be the 'only supreme head on earth of the Church of England.' A document was at the same time drawn up by the government, in which it was explained that the recognition of this headship of the church implies only that the king should have such power as of right appertaineth to a king by the law of God, and that he should not take any spiritual power from spiritual ministers, or pretend to 'take any power from the successors of the apostles that was given them by God.' In 1535, the year in which this act was passed, Bishop Fisher of Rochester, Sir Thomas More, and others were beheaded for denying the king's supremacy. On Elizabeth's accession it was thought prudent, while again claiming the supremacy in all causes, as well ecclesiastical as civil, to keep that designation in the background. By successive statutes the oath of supremacy was appointed to be taken by the holders of public offices along with the oath of allegiance and of abjuration; these three oaths were consolidated into one in 1858; and now the oath of supremacy is not explicitly imposed on members of parliament. See OATH, ENGLAND (CHURCH OF), HENRY VIII.

Supreme Court of Judicature. in England, comprises the Court of Appeal (q.v.) and the High Court of Justice, with its four divisions—Chancery, Common Law, Bankruptcy and Probate, Divorce and Admiralty, all separately dealt with. In Scotland the term refers to the Court of Session (q.v.) and the Justiciary Court (q.v.).

Surabaya, or SOERABAJA, the largest city of Java, and capital of the residency of Surabaya, is situated on the north coast on the strait of Madura, over against the island of Madura. The town serves as an export centre for the rich eastern region, and has well-constructed harbour-works and a good roadstead. It is the principal naval base of the Dutch East Indies, and has a naval arsenal and

several shipbuilding-yards. Sugar, coffee, hides, and tobacco are the chief articles exported; rice and cotton are also grown in the province. Pop. 192,000.

Suraja Dowlah. See BLACK HOLE, CLIVE.

Surakarta, or SOERAKARTA, a town in the centre of Java, but connected by rail with Samarang on the north and Surabaya on the east. It is the residence of the native sultan of Surakarta, who, however, is a dependant of the Dutch government and is advised by a resident. The town (pop. 134,000) is the capital of his kingdom, a mountainous but in part very fertile region.

Surat, a city of British India, on the south bank of the river Tapti (crossed by a five-girder bridge), 14 miles from its mouth, and 160 by rail N. of Bombay. It stretches in a semicircle for more than a mile along the river, the quondam citadel (1540; government offices since 1862) forming the central feature in the line. The houses are closely packed, but the streets are clean and well paved; beyond them lie the suburbs, widespread in the midst of gardens. The chief ornaments of Surat are four handsome Mohammedan mosques, two Parsee fire-temples, three Hindu temples, the old English and Dutch factories, and a clock-tower (80 feet high). The existing city was founded early in the 16th century, and very soon after (in 1512) was burned by the Portuguese, who burned it again in 1530 and 1531. A stronger fort was erected in 1546, and Surat, already a place of considerable trade, soon rose to be one of the greatest commercial cities of India. In 1612 the English established themselves there, in spite of the opposition of the Portuguese, and shortly after they were followed by the Dutch. These last were the busiest of the European traders. Surat at this time had commercial relations with western Europe, with the great cities of Northern India, with Arabia, Persia, the coast-towns of Southern India, Ceylon, and the East Indies, silk, cotton, and indigo being the most valuable exports. Here, too, the Mohammedan pilgrims of India were wont to embark for Mecca. Shortly after the middle of the 17th century the Mahrattas began to harass the city, and they pillaged it several times before the century ran out. But towards the end of the 17th century the commerce of Surat began to decline, Bombay gradually taking its place, especially after the East India Company transferred to that city the headquarters of their government. Just previous to this change Surat is believed to have had a population of 200,000. The place was transferred to English rule entirely in 1800, and for a time it had a revival of its old prosperity and became the most populous city in India. But by a quarter of a century later it had once more declined, and in 1837 was almost wholly ruined by a disastrous fire followed by a great flood. In 1858 it began once more to revive, and flourished during the period of the American civil war, its chief export being cotton. Pop. (1811) 250,000; (1847) 80,000; (1881) 109,840; (1921) 117,434. Cotton, silk, brocade, and embroidery are manufactured.

Surbiton. See KINGSTON-UPON-THAMES.

Surcouf, ROBERT, a great French privateer, was born at St Malo, 12th December 1773, and died there, a taciturn but prosperous and corpulent boat-builder, in 1827. He preyed on the English shipping in the Indian seas during the long war, and showed extraordinary skill and courage. His greatest exploits were the capture of the Company's ships *Triton* of 800 tons (1785) and of the *Kent* (1800), almost at the end of her voyage from England to Calcutta. See Loughton's *Studies* (1887); Statham's *Privateering* (1910).

Surd. See IRRATIONAL NUMBERS.

Surety. See GUARANTY.

Surface-tension, in liquids, is that property in virtue of which a liquid surface behaves as if it were a stretched elastic membrane—say a sheet of india-rubber. We owe the idea to Segner (1751); but it was Young who, in 1805, first applied it successfully to the explanation of various physical phenomena, such as those of capillarity. The whole subject was subsequently developed in its complete mathematical form by Laplace and Gauss. The general description of the meaning of surface-tension has been given under CAPILLARITY. Here we shall refer to a few other phenomena, which require for their elucidation the assumption of a tension existing in liquid surfaces. Pure water has the highest surface-tension of any ordinary liquid except mercury. If a little alcohol be dropped on the water, the surface-tension will be diminished there. The more powerful surface-tension over the pure water will show its superiority by pulling the alcohol over the whole surface until the surface is reduced to uniformity, and equilibrium produced. Again, a piece of camphor placed on water will dart from place to place in the most capricious manner. This is due to the irregular way in which the camphor dissolves in the water, so that the surface-tension is more weakened on one side than on the other. It is the action of surface-tension that draws out all over the surface any impurities that may settle on it; and hence arises the great difficulty of getting a clean water or mercury surface. Drops of liquid, free from all but their own molecular forces, assume spherical forms, this being the only shape consistent with equilibrium under the influence of equal surface-tension at all parts of the curved surface. Ripples on the surface of any liquid progress because of the action of surface-tension, which gives rise to an inward pressure on any convex surface. The laws governing the propagation of ripples on the surface of mercury were carefully studied by Professor C. Michie Smith and Lord Rayleigh. Some very instructive experiments may be made with soap-films (see SOAP-BUBBLES); while in cohesion figures we have some very exquisite phenomena, which have been closely studied by Tomlinson. These are produced by dropping a dark-coloured liquid into a transparent liquid of slightly smaller density. Ordinary ink dropped into water will serve the purpose very well, although better effects are obtained with a solution of permanganate of potash. As the drop meets the water-surface, the action of the surface-tension pulls the under surface of the drop outwards, and transforms the drop into a vortex ring, which slowly sinks through the clear fluid. As it so sinks it breaks up into smaller rings and shoots out fantastic ramifications of rare beauty. Ultimately, of course, under the influence of diffusion, the vortex motion decays and the dark liquid mixes with the clear liquid.

Surf-bird (*Aphriza virgata*), a plover-like bird found on the Pacific coasts of North and South America, akin to sandpipers and turnstones, and sometimes called Boreal Sandpiper.—The Surf-duck or Sooter is treated at SCOTER.

Surgeons, COLLEGE OF. The present Royal College of Surgeons of England dates its origin from 1460-61, when Edward IV. 'did, at the supplication of the freemen of the mystery of barbers of the city of London using the mystery or faculty of Surgery, grant to them that the said mystery, and all the men of the same mystery of the said city, should be one body and perpetual community.' An act of 1511 prohibits any one from practising as physician or surgeon unless duly examined and admitted. Hence arose a company called the Sur-

geons of London. In 1540 the Company of Barbers of London and the Company of Surgeons of London were united; it was not till 1745 that the surgeons of London were by act of parliament separated from the barbers of London, and made a distinct corporation under the name of 'the Master, Governors, and Commonalty of the Art and Science of Surgery of London.' This company was dissolved, and in 1800 replaced by 'the Royal College of Surgeons of London.' A new charter granted in 1843 to the Royal College of Surgeons of England gave power to the council to elect not less than 250, nor more than 300, members of the college to be Fellows. By an addition to the charter, obtained in 1852, power was given to the council, subject to certain regulations, to appoint members of fifteen years' standing to the fellowship without examination. The college was likewise empowered to test the fitness of persons to practise midwifery, and to grant certificates; in 1859 it was authorised to grant certificates to dentists; in 1888 additional powers were conferred, but the duty of examining in midwifery was withdrawn; and in 1890 the council of the society was empowered to elect fifty honorary fellows.

The government of the college is vested in a Council of twenty-four members, with a president and two vice-presidents. There is a Board and a Court of Examiners for the fellowship, and examining boards for the membership. There are professorships of comparative anatomy and physiology, of surgery and pathology, and of dermatology, besides lectureships. A Hunterian Orator is appointed every second year. The museum of the College of Surgeons is incomparably the finest museum of its kind in the United Kingdom. The Hunterian Collection (see HUNTER, JOHN), which forms its basis, was purchased by a parliamentary vote of £15,000, and presented to the college in 1799. The original edifice in Lincoln's Inn Fields (the germ of the present pile of buildings) was completed in 1813. See the Calendar of the college.

THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH obtained the first charter to the 'Surgiculis and Barbouris' in 1505, and had it confirmed by James IV. next year. For a century and a half the members of the guild were sole teachers and almost sole professors of the surgical art in Edinburgh. In 1694 they obtained from the town-council a grant of the bodies of convicts and foundling infants; in 1705 the professorship of anatomy was founded; about the same date botany, chemistry, and physic were taught; in 1726 the teachers of theory of physic, practice of physic, and chemistry were constituted professors of medicine in the town's college, and from this time the constitution of the medical school in the university dates. In 1778 the College of Surgeons became a royal college. The present building, dating from 1832, possesses a fine museum. The college grants the diplomas of Fellow, Licentiate, Licentiate in Dental Surgery, a Higher Dental diploma, and a diploma in Public Health; 300 diplomas were granted in 1926, including 19 to women. The Royal College of Surgeons in Ireland was incorporated in 1786; see history by Cameron (1886).

Surgery includes all manual operations, either by the hand alone or more frequently with the aid of instruments or appliances, in injuries or malformations of the body. From very early times there has been a tendency to divide those who practise the healing art into surgeons who deal with the treatment of wounds and perform operations, and physicians who deal with internal maladies. Certain operative procedures, such as the stitching of wounds, application of splints to fractures, and opening of abscesses, are so obvious that they are practised by the most primitive

peoples. Even more elaborate processes of treatment date from a very early time; for example, splints from before 3000 B.C. have been found in 5th-dynasty Egyptian graves, and the operation of couching a cataract was known among the early Babylonians of 2000 B.C. Circumcision, castration, the removal of tumours by knife or cautery were also practised by these peoples; and instruments, such as knives, probes, forceps, saws, and trephines, have been found both in Nineveh and in Egyptian tombs.

Among the Indians, surgery as well as medicine occupied a high position. Various medical procedures came down from remote antiquity, and by the time of Sūruta (see SANSKRIT) surgery was practised with considerable skill. The instruments, numbering over 100, were finely made of steel, cleanliness and neatness were demanded of the operator, the student was taught how to make incisions by experimenting on fruits, plant stems, or leather bags. The surgeons could operate for fistula in ano, and stone in the bladder, and in extreme cases they did not hesitate to open the abdomen. The reparation of deformities, e.g. of the nose by skin-grafting, and the removal of cataract by couching, were matters in which they showed special skill.

Among the other Eastern nations, surgery was not highly developed. From several centuries B.C. Greek medical men were valued as surgeons at the Persian court. The Chinese performed some operations, e.g. castration, in a rough fashion, and made great use of acupuncture by gold and silver needles, and of the moxa or burning cone. They seem, however, to have had considerable knowledge of anæsthetic drugs.

Western surgery had attained a high degree of development in Greece by the time of Hippocrates (460-370 B.C.). Many of the treatises in the Corpus Hippocraticum show great skill especially in treating wounds and injuries of the bones and joints, for which experience was doubtless derived from the injuries that often occurred in the gymnasia and athletic schools. The surgeons undertook trephining, incision of the pleura, tapping the abdomen, nephrotomy, amputation of gangrenous limbs, numerous small operations like those for hæmorrhoids and fistula, and a host of skilful manipulative devices in dislocations and fractures. To their list of instruments belonged sponges, probes, cupping-vessels, cauteries, knives of steel, dissectors, retractors, spatule, respirators, trephines, bladders with tubes for injections, catheters, specula, forceps, and the 'scamnum Hippocraticum,' a bench provided with pegs and pulleys for various manipulative operations. Hippocrates describes healing by first intention, which he recommends, and that by pus formation. The special dangers attending wounds of the throat, groin, and large joints were well recognised, and tetanus was a much-dreaded complication. In the treatise on *Wounds of the Head* there is a masterly description of head injuries, for which trephining was very frequently practised, usually on the third day. Fractures were set with roller bandages, and splints or methods of extension were applied on the seventh day, while compound fractures were washed and dressed with wine. Lithotomy was not undertaken by the general surgeon, but left to special practitioners of that operation, and there is little about hernia in the Hippocratic writings.

The Alexandrian school contained several celebrated surgeons whose names have been recorded by other writers. Herophilus and Erasistratus were specially famous as anatomists, Philoxenus for improvements in surgical practice, Ammonius as a lithotomist. Julius Caesar, by conferring

civic rights at Rome upon medical practitioners from Egypt and Hellenic lands, greatly stimulated their immigration to that city. One of the earliest of these, Asklepiades, introduced the operation of tracheotomy. Native Roman surgery had been of a very primitive type. Cato (234-149 B.C.) had given in his *De Re Rustica* simple rules and charms for treating fractures, ulcers, retention of urine, &c. Archagathus (218 B.C.), known at first from his skill in treating wounds as 'Vulnerarius,' had been provided at the public expense with a 'taberna' for his operations, where he subsequently became so fond of the knife that he was termed by the populace 'Carnifex' or the 'Butcher,' and had to leave the city.

In the first century of the Christian era, Celsus, himself a Roman patrician, gives an admirable account of surgery as practised in his time, drawn mainly from the Alexandrian teachers. In the treatment of wounds, he recommends various sulves which contain both antiseptic and astringent substances; bleeding is valuable against inflammation; the ligature is to be used for arrest of hæmorrhage; and minute details are given for trephining, amputation, radical cure of hernia, lithotomy, stitching of the wounded large intestine (though wounds of the small intestine were said to be always fatal), urethrotomy, removal of goitre, &c. Among the contemporaries of Celsus was Heliodorus, in the reign of Trajan, who ligatured or twisted blood-vessels for arrest of hæmorrhage, performed a radical cure for hernia, and amputated by the circular or flap incision. Another contemporary, Antyllus, removed cataract by extraction and suction, and treated aneurysm by applying ligatures at either end, and opening the sac between them. A great number of surgical instruments belonging to the time of the early empire was found in the house of the surgeon at Pompeii (buried 79 A.D.); these consist of over 200 different forms of instrument, e.g. probes, sounds, spatula, artery forceps with ring catch, tooth forceps, sequestrum forceps, catheters, needles, dilating specula, saws, syringes, knives, shears, cupping vessels, arrow extractors, &c. Many other collections have been discovered elsewhere. Galen, though in early life he acted as surgeon to a school of gladiators, later practised in Rome as a physician, so that surgical references occur infrequently in his works. Leonides about his time was a skilful operator acquainted with the cæcæum, dissected out the cervical glands when enlarged, and amputated by the flap method.

In the Eastern empire surgery fairly maintained the high standard set by Celsus and his contemporaries, as may be judged from the books compiled by Oribasius (4th century) and Paulus of Ægina (7th century). The latter in his celebrated sixth book gives descriptions of lithotomy, trephining, tonsillotomy, amputation of the breast, but in describing the radical cure of scrotal hernia commits the mistake of recommending removal of the testicle, which was perpetuated by the Arab surgeons. He also gives good accounts regarding the surgery of the eye, removal of weapons, and operations on the genital organs. Military medical services were well organised, and, in addition to the ordinary medical officers with the cohorts and legion, there were, as described in the Emperor Maurice's book *On Tactics* (about A.D. 590), ambulance companies whose duty was to bring the wounded to the rear, and who were provided with water-flasks. The foundations of military hospitals in permanent camps have been discovered showing that these were spacious handsome buildings, and to them 'nosocomi' or male nurses were attached. The Arabs, from the 7th to the 13th century, followed Greek medicine, taking the

details of their operations chiefly from Paulus of Aegina, and showing little originality. Abulcasis (11th century) of Cordova was their most celebrated surgeon, and the most noteworthy character of his work on surgery lies in the numerous illustrations of instruments that it contained. A striking feature of his practice was his great fondness for cauteries of all shapes and sizes which he used for incisions, arrest of bleeding, &c.

Until the rise of the universities in the 12th century Western surgery, like medicine, was chiefly in the hands of churchmen, although various edicts were issued against this practice, culminating in that of the Council of Tours (1163), 'Ecclesia abhorret a sanguine.' Still, this did not deter highly-placed churchmen like Guy de Chauliac and Bishop Theodoric from being the most distinguished surgeons of their age. These edicts were issued largely, no doubt, because of the discredit attaching to the vagaries of the strolling and ignorant mountebanks who also practised surgery during its state of disorganisation before the rise of the universities and guilds. As a consequence of the serious injuries often inflicted by the ill-qualified, the mediæval surgeon went constantly in fear of life or limb from the vengeance of patients or their friends. Even celebrated surgeons, like Hugh of Lucca and Roland of Parma, as late as 1250 refused to operate on the injured lung of a Bolognese nobleman till thirty of his friends had given them an oath that no harm should befall them in the event of failure. Minor surgery passed gradually into the hands of the barbers, and in London a Barbers' Company was organised by the 13th century; in Paris they were united in a corporation about the same time; similarly in other cities. In time of war the great bulk of the surgical staff required was drawn from the barbers. These had later a considerable amount of special training, as in the lectures on anatomy at Edinburgh in 1505 to the 'surgeonis and barbouris,' and the similar courses at the Collège de St Côme in Paris, and of Banister to the barber-surgeons of London in 1581. Apart from the barbers we find a limited number of celebrated surgeons in the middle ages, including Roger of Palermo, who wrote a treatise on *Practical Surgery* (1180), and his pupil Roland of Parma; William Salicet (1201-77), who recommended suture of divided nerves; Lanfranc, who set up in Paris (1295), and was the virtual founder of French surgery; Henri de Mondeville (1260-1320), an early exponent of aseptic surgery; Jehan Yperman (1295-1351), the great surgeon of the Low Countries; and Heinrich von Pölspondt, who, in his *Wound-surgery* of 1460, gives the first account of gunshot wounds. The greatest name in surgery during the middle ages is that of Guy de Chauliac (1300-70), whose cultured and interestingly-written *Chirurgia magna* (1363) gives the best picture extant of mediæval surgery, and remained the authoritative work till the time of Ambroise Paré. John of Vigo uses this author extensively in his *Practica Copiosa* of 1514, wherein he is the originator of the theory that gunshot wounds are necessarily poisoned, a theory which called for the use of boiling oil in treatment of wounds, and inflicted a great deal of unnecessary suffering upon the injured.

The chief effect of the Renaissance on surgery was exerted through the revival of anatomy, of which the most striking monument is the handsomely illustrated *Structure of the Human Body*, published by Vesalius, professor at Padua, in 1543. The improved teaching of anatomy made more skilful surgery feasible, and the four great representatives of Renaissance surgery are Ambroise Paré (1510-90), who, beginning life as a barber, elevated himself by strenuous work during the

French wars to be surgeon to several kings of France, and is renowned for advocating a mild treatment of gunshot wounds and for reintroducing the ligature; Pierre Franco (1505-70), who gave the earliest known account (1556) of the relief of strangulated hernia; Gasper Tagliacozzi (1546-99), who introduced plastic surgery of the face, especially the repair of the nose; and Fabricius Hildanus (1560-1624), the 'father of German surgery,' who wrote an original work on *Six Hundred Surgical Cures and Observations*. Scultetus gives a good sidelight on the operations of his time in the illustrations of his *Armentarium Chirurgicum* (1653). In England, William Clowes, surgeon to Queen Elizabeth, wrote an excellent treatise on gunshot wounds (1591), and Richard Wiseman, who served on the royalist side through the Civil War, in his *Several Chirurgical Treatises* (1672), did for clinical surgery what his contemporary Sydenham did for clinical medicine; he was also the first to recognise the identity of tuberculosis in the bones and joints with this disease in the lungs.

In the 18th century a great school of anatomists and surgeons arose in England, of whom the brothers William Hunter (1718-83) and John Hunter (1728-93), who both founded great pathological museums, are the most famous. Indeed the great feature of the latter half of the 18th century both in England and on the Continent was the ardour with which the most distinguished surgeons developed anatomy. W. Cheselden (1688-1752), who introduced the operation of lateral lithotomy; Percival Pott (1714-88), who wrote several masterly monographs on hernia, fractures, and spinal deformity, were also well-known operators and teachers in London. In France, Petit (1674-1750) invented the screw-tourniquet, and was the first to open the mastoid process; Avel treated aneurysm by a single ligature (1710); Brunsdorff (1721-97) introduced the distal ligature; Desault and Chopart are also well-known names. In Italy, Scarpa (1747-1832) was distinguished both for his research in anatomy, his skill in orthopaedic surgery, and for the admirable skill with which he illustrated his own works. In Germany, L. Heister published his *Chirurgie* (1718), which became the most popular text-book on surgery, and is of unusual interest still for its admirable illustrations of surgical treatment at that time. A striking example of the social status of the average surgeon on the Continent during this century is found in the fact that one of the duties of the Prussian and Austrian army surgeons was to shave the officers; but a great advance in education and in status followed the founding of the Collegium Medicum-Chirurgicum and Charité Hospital in Berlin (1727), of the Josephinum or Medico-Chirurgical Academy at Vienna (1785), and of the Collegium Medicum at St Petersburg (1763).

The 19th century begins with the distinguished surgeons of the Napoleonic wars. Larrey (1766-1842), whose most interesting work was his *Memoirs of Military Medicine*, was surgeon-in-chief to the Grand Armée, the inventor of the celebrated 'flying ambulances,' and a man of immense popularity for his courage, good-nature, and humanity. Dupuytren, celebrated especially for his *Injuries and Diseases of the Bones*, Lisfranc, Delpsch, Velpeau, Malgaigne, and Nélaton carried on the development of surgery in France. The leading English military surgeon of the wars was G. J. Guthrie (1785-1856), who after Waterloo published his *Treatise on Gunshot Wounds of the Extremities requiring Amputation*, which has saved many injured limbs. In England, Sir Astley Cooper (1768-1841) occupied a great place in the public eye, achieved extraordinary success in practice,

produced books on hernia, injuries of the joints, and diseases of the testis, and was a most indefatigable dissector. Sir B. C. Brodie was the acknowledged head of the profession in London for many years, wrote a classic treatise on the *Pathology and Surgery of the Joints*, and was the pioneer of subcutaneous surgery. A. Colles, professor of surgery in Dublin, is celebrated for his description of the fracture of the forearm which bears his name, and for his *Practical Observations on the Venereal Disease* (1837). The Edinburgh school was represented by the brothers John Bell and Sir Charles Bell (1774-1842), both possessed of great artistic as well as surgical talent, and the latter celebrated as a physiologist and anatomist; Liston, who introduced many new procedures; James Syme (1799-1870), who was the first to adopt excision of diseased joints (1831) in preference to amputation; Sir W. Fergusson (1808-77), who is regarded as the founder of conservative surgery; and Lizars (1783-1860), who was one of the first to remove the lower jaw and to perform the operation of ovariectomy. In Germany, Langenbeck (1776-1851) was celebrated for his extraordinary speed in operating; and in Russia, Pirogoff (1810-81) is regarded as the greatest figure in the surgical development of that country. In America, Valentine Mott (1785-1865) greatly developed the surgery of blood-vessels, Ephraim McDowell (1771-1830) was the earliest ovariectomist, and J. Marion Sims (1813-83) became one of the greatest operators in the domain of women's diseases.

The introduction of anæsthetics inaugurated a new period in surgery by permitting longer and more elaborate operations than were possible before. In 1800 Sir Humphrey Davy had experimented with nitrous oxide gas; in 1846 the first surgical operation was performed under ether administered by Morton; and in 1847 Simpson introduced ether and, later, chloroform into obstetric practice. Surgeons had been rendered much more familiar with the bodily functions and reparative powers through the experiments of Magendie, Claude Bernard, and other physiologists. In 1847 Semmelweis discovered the nature of blood-poisoning and of child-bed fever, and his work was amplified and incorporated into practical surgery by the researches of Lister from 1865 onwards. Since this time many disinfectants and antiseptic procedures useful for different purposes have been introduced, and the harmful properties of various bacteria have been carefully studied on the foundations laid by Pasteur and Koch from 1870 onwards. It is an interesting comment on the progress of abdominal surgery that, while in 1855 we find Sir George Ballingall stating 'no man in his senses would think of enlarging the external wound for the purpose of searching out and sewing up the wounded part of the gut,' by 1881 Billroth, the pioneer of visceral surgery, for the first time excised a cancer of the stomach with success, and between 1878 and 1883 had performed various excisions of the intestine. Other pioneers of the later 19th century were Mieniez, Czerny, von Volkman, von Eschsch, von Bergmann, von Graefe in Germany; Paget, Hutchinson, MackEwen, Horsley, Spencer Wells, Lawson Tait in Britain; Kocher in Switzerland; and Bigelow, Senn, and Murphy in America. The general establishment of pathological and experimental institutes in the last decades of the 19th century did much to diffuse the knowledge of surgery and to increase the precision and safety of operations; while the discovery of X-rays in 1893 and their application in diagnosis has proved of immense assistance, particularly in regard to injuries of the bones and diseases of the alimentary tract. All these in-

fluences have contributed to swell the numbers of abdominal operations to their present great proportions.

Following upon the more accurate knowledge regarding the functions of the various parts of the nervous system that has been afforded by advances in physiology and clinical medicine, the surgery of the brain and spinal cord has reached a high degree of efficiency. In this also the help which has been rendered by X-rays in localising injuries and foreign bodies has played a considerable part. In the surgery of the urinary tract, the increased knowledge derived from advances in chemistry, the invention of ingenious instruments, such as the cystoscope, by which the interior of the bladder may be inspected, and, in a very high degree, the help of X-ray examination have brought a great degree of precision to operations on the kidney and bladder. The surgery of the eye and ear has greatly developed in the matter of finer and more successful operations for dealing with disease in these organs. Even in general surgery, the removal of tumours, the conservation of tuberculous bones and joints, the repair of bones and other tissues by grafting, and the more uniformly successful treatment of injuries have all shown a great advance. Finally, the experience of the Great War has not only effected the introduction of many new improvements in surgical technique, but has proved of great educational value to surgeons scattered throughout country districts, whereas formerly the practice of operative surgery was largely restricted to the teachers in the great medical schools.

For the bibliography of works which give the fullest and most trustworthy account of the healing art, surgical as well as medical, see the article on MEDICINE. Monographs like Wise's *History of Medicine among the Asiatics*, Young's *Annals of the Barber-Surgeons of London*, Struthers's *Historical Sketch of the Edinburgh Anatomical School*, Parker's *Early History of Surgery in Great Britain* (London, 1920), Miles's *Edinburgh School of Surgery before Lister* (London, 1918), and Cameron's *History of the Royal College of Surgeons in Ireland* may also be consulted. Special operations in surgery (Lithotomy, Ovariectomy, &c.) are dealt with under their respective heads, or in connection with the articles on such subjects as AMPUTATION, APPENDICITIS, CATARACT, DISLOCATION, EYE, FRACTURES, HIP-JOINT, SHOULDER-JOINT. There are articles on CATIETHER, FORCEPS, OPHTHALMOSCOPE, RÖNTGEN RAYS, STETHOSCOPE, TOURNIQUET, &c. See also the articles in this work on the great surgeons.

Suricate (*Suricata tetradactyla*), a South African carnivore belonging to the Viverridae, of which civet and mongoose are representatives. Body and head reach a length of 12 or 13 inches, tail 6 inches; there are only four toes, and the claws are very long, suited for burrowing. This furry, largely vegetarian, gregarious creature—in captivity an amusing and delightful pet—is also called Zenick and Meerkat (Dutch, 'sea-cat'); the latter name also given to the related *Cynictis penicillata*.

Surinam. See GUIANA (DUTCH). For the Surinam Tord, see AMPHIBIA.

Surplice (Lat. *superpellicium*, 'above the robe of fur' worn by the monks from the 9th century), a white linen garment worn over the cassock by clerks of all degrees. Its most ordinary use is for the service of the choir, and it is also employed, along with the stole, by priests in the administration of the sacraments, and in preaching. The use of the surplice was strongly objected to by the Calvinistic and Zwinglian reformers on the Continent, and by the Puritans in England, who regarded this vestment as a relic of popery, and made it the subject of vehement denunciations.

Ere ritualism became so common in England, no little stir used from time to time to be created by the use of the surplice, instead of the Gown (q.v.), in the pulpit, contrary to the more general practice in the Anglican Church. The length of the surplice varies, never in the Roman Church coming below the knees; the short Italian *cotta*, adorned with lace, dates from about the 17th century.—*Surplice-fees* are payments to the clergy by the laity when any sacred functions—baptisms, marriages, funerals—are performed for the latter's benefit.

Surra, a disease of horses in India and eastern Asia, caused by a Trypanosome.

Surrender. See CAPITULATION.

Surrey, an inland county in the south of England, is bounded on the N. by the Thames, which separates it from Middlesex, E. by Kent, S. by Sussex, and W. by Hants and Berks. Its maximum length from east to west is 39 miles; greatest breadth, 26 miles; and it contains 461,833 acres. Pop. of administrative county, with the county borough of Croydon (1921), 930,377. Far-famed for the beauty of its scenery, Surrey is traversed from east to west by the North Downs (see DOWNS), which, near Titsey on the Kentish border, rise to the height of 880 feet; on the north side of this range the land slopes gradually to the banks of the Thames—though even there plenty of high ground is to be found, as Cooper's Hill, St George's Hill, Richmond Park, and Wimbledon Common—but on the south the descent is rugged and broken up before the level of the Weald is reached. South of the main range, and about 5 miles distant from Dorking, is Leith Hill (967 feet), the highest point in the county, whilst in the extreme south-west rises Hind Head (903 feet). From all these places, as also from many others—e.g. the Hog's Back, St Martha's Chapel, and Newland's Corner (both near Guildford), Box Hill, the downs above Reigate and Epsom, and at Virginia Water—glorious views are to be obtained, a noticeable feature in the landscapes being the prevalence of commons and heath-lands—the latter chiefly in the west—scattered throughout the county. Of rivers the most important are the Wey and the Mole, both tributaries of the Thames. The soil of the northern half of the county is fertile, especially in the vicinity of London, where large tracts are occupied by market-gardens and nursery-grounds, but in the centre and southern districts the land is of a poor quality, consisting mostly of sand and chalk; it is well wooded, box-trees especially growing in great profusion, and around Farnham are hop-grounds. Croydon, Guildford, Kingston, and Reigate are—not reckoning the suburbs of London—the principal manufacturing centres and most important towns. Near the last-named extensive beds of Fuller's Earth (q.v.) are found. The county is divided into fourteen hundreds, and since 1918 has returned seven members to parliament, not including the boroughs of Croydon (2 divisions), Wimbledon, Richmond, and Kingston.

In history Surrey has played but a meagre part, the only incident of importance of which it was the scene, other than those noticed under Kingston, being a defeat of the Danes at Ockley in 851. Between the two last-named places traces of the old Roman road between London and Chichester are plainly visible, whilst on Wimbledon Common, Hascombe Hill, and near Aldershot are Roman encampments. Of buildings of an architectural or historical interest the castles of Farnham and Guildford and the ruined abbeys of Newark and Waverley most call for attention, whilst at Claremont, Outlook Park, and Sheen (now Richmond), were royal residences; nor must mention be omitted

of the quaintly-timbered old houses—many of them moated—abounding in the district around Gomsall, Godalming, and Haslemere.

See works by Manning (3 vols. 1804-14), Allen (2 vols. 1829-30), Brayley (5 vols. 1841-48), Bevan (1891), Murray's *Handbook*, and *Surrey* in the 'Victoria County History' (ed. Malden, 1902-14).

Surrey, HENRY HOWARD, EARL OF, poet, was born between 1516 and 1518, most probably in Suffolk, either at Framlingham or Tendring Hall, the eldest son of Thomas Howard (q.v.), who in 1524 succeeded as third Duke of Norfolk. In 1532 he was married to Lady Frances Vere, daughter of the Earl of Oxford, in the same year accompanied Henry VIII. to France, and afterwards spent about twelve months in study at Paris in company with Henry's natural son, the young Duke of Richmond, who was affianced to his only sister, but died an untimely death in 1536. Surrey's eldest son Thomas was born that same year, and it is interesting that the child's nativity, which still exists, foretold dark disaster to the father. It was soon after this that his romantic passion for the fair but disdainful Geraldine awoke, unless she is to be relegated to the domain of fancy in the same sense as Héloïse, Petrarch's Laura, and Tasso's Leonora. It seems certain, however, that if she had real existence she was the Lady Elizabeth Fitzgerald, the second of the three daughters by his second marriage of Gerald, ninth Earl of Kildare. But the story is surrounded with difficulties, and we are not helped by Thomas Nash's absurd account (*Unfortunate Traveller*, 1594) of how Surrey traversed Italy like a knight-errant for his mistress' sweet sake. His second son, afterwards Earl of Northampton, was born in 1539. In 1542 he was made a Knight of the Garter. Later in the same year he lay some time in the Fleet for challenging a gentleman with whom he had quarrelled, and next year he was again committed for roystering and breaking windows in the streets at night. Soon released, he went to serve in the camp before Landrecy near Boulogne, and returned in winter to complete his beautiful seat of Mount Surrey near Norwich. It was at this time that he admitted to his household the physician Hadrian Junius and the poet Churchyard. Again in 1544 Surrey went to France as marshal of the invading army, and distinguished himself at the siege of Montreuil, being severely wounded in the attempted storming (19th September). Again next year we find him holding command at Guisnes and at Boulogne, and defeated by a superior French force in the beginning of January, for which he was soon superseded by the Earl of Hertford, who, as uncle to the heir to the throne, looked forward to a regency on the king's death, and at once feared and hated the Norfolk party. For his bitter speeches against Hertford Surrey was imprisoned at Windsor in July, and on the 12th December was, like his father, committed to the Tower on a charge of high-treason. His offence was merely that he had assumed the arms of his ancestor Edward the Confessor, in conjunction with his own proper arms, a thing which by all the laws of heraldry and common usage he was perfectly entitled to do, and which, moreover, had been specially allowed the Duke of Norfolk by Richard II. His father's mistress and his own sister gave evidence against him, and, though he defended himself with singular ability at his trial at the Guildhall on the 13th January 1547, he was found guilty by the jury, condemned to death, and beheaded eight days later, 21st January 1547. His body was first buried in All Hallows-Barking, Tower Street, but was removed by his son, the Earl of Northampton, to Framlingham Church, where it rests under a stately monument of black and white marble.

Surree's character would seem to have been much less amiable than it appeared to his eulogist, Dr Nott. He was proud, headstrong, and imprudent, and his unkindness to his mother remains a blot upon his memory, however unworthy of respect she may have been. His poems seem to have circulated freely in manuscript during his lifetime, but were not printed till 1557, when they appeared, together with poems by Wyatt and others, in *Tottel's Miscellany*. They consist of sonnets, lyrics, elegies, translations, paraphrases of the Psalms of David and Ecclesiastes, besides translations in good blank verse—the first in English—of the second and fourth books of Virgil's *Æneid*, the last not given in Tottel but printed by Day (1554?). As a poet he shows grace, delicacy, a quick eye for the beauties of nature, and a sensitive ear to the harmonies of versification. His love-poetry follows Petrarch too closely, yet not without a truth and genuineness of feeling of its own. He was not only the first in English to employ the sonnet, but within his range he had mastered the difficulties of that artificial form.

See editions by Dr Nott (1815-16 with Wyatt); in 'Aldine Poets' (1831; 1866); and by Padelford (1920); Miss Willcock's study in *Mod. Lang. Rev.* (1919-22); and Berdai's *Early Tudor Poetry* (1920).

Surtees, ROBERT, born at Durham, 1st April 1779, graduated B.A. from Christ Church, Oxford, in 1800, and, after less than two years at the Middle Temple, in 1802 came into his paternal estate of Mainsforth, near Bishop Auckland. Here till his death on 11th February 1834 he largely devoted himself to the compilation of his *History and Antiquities of the County Palatine of Durham* (vols. i.-iii. 1816-23), to vol. iv. of which (1840), completed by the Rev. James Raine, a memoir by George Taylor is prefixed. To Scott's *Minstrelsy* Surtees contributed two 'ancient' ballads he himself had made—*Barthram's Dirge* and *The Death of Featherstonhaugh*. The Surtees Society, founded in 1834 for the publication of unedited MSS. relating chiefly to the northern counties, had issued a hundred volumes before the end of the century.

Surtees, ROBERT SMITH (1803-64), of Hamsterley Hall, Durham, wrote anonymously a series of inimitable sporting novels, introducing Mr Horrocks, grocer and sportsman. Among the best known are *Handley Cross* (1843, 1854); *Mr Sponge's Sporting Tour* (1853); *Ask Mamma* (1858); *Plain or Ringlets?* (1860); and *Mr Farey Romford's Hounds* (1865)—all illustrated by John Leech and 'Phiz.' See *Robert Smith Surtees* by himself and E. D. Cumming (1924).

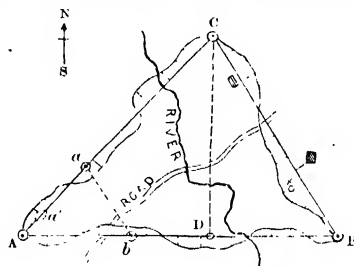

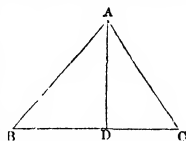

Surturbrand, a kind of Lignite (q.v.) found interstratified with basalts and tuffs of Tertiary age in Iceland and the Faeroe Islands.

Surveying. Land surveying may be considered the earliest practical application of the art of geometry or earth measurement, and must have been in some more or less rude form coeval with agriculture and the division or appropriation of the soil. In Rome surveying was considered one of the liberal arts, and the measurement of lands was entrusted to public officers who enjoyed certain privileges; and it is probable that the system of measurement practised by them was very similar to our plain surveying with the chain and cross-staff of the present day, and has been handed down to us through the feudal period. An exam-

ination of ancient records and title-deeds will show that both areas and boundary lines of the different enclosures forming fields, hundreds, town-lands, &c., are often laid down with much accuracy.

Land-surveying may be considered under the following heads: (a) Plain surveying with the chain, and without the aid of angular instruments, except the cross staff or fixed angle of 90°; (b) modern engineering surveying, in which angular instruments are used; (c) coast and military surveying; (d) trigonometrical surveying.

The fundamental rule of every description of

The line ab may be similarly booked and platted.

land-surveying, from the humblest attempt to lay down an irregular garden-plot to the trigonometrical survey of a large extent of the earth's surface, when the aid of the most refined improvements of modern science is indispensable, is simply to determine three elements of a triangle, and thence to calculate its area.

In plain surveying with the chain the three sides of the triangle, ABC, are supposed to be accessible, and are carefully measured on the ground, and then laid down or platted to scale on paper, when an accurate figure of the triangle will be obtained, on which the length of the sides can be marked. To get the area, however, it will be necessary to determine the length of the perpendicular line AD, and this is usually done (when possible) on the ground by means of a simple instrument called a cross, which consists of two sights or fine grooves at right angles to each other; which being placed on the line BC (keeping B and C visible in one of the sights), nearly opposite the angle A, is moved gradually till the angle A is intersected by the other sight. The line AD can also be laid down on the drawing, and its length found by scale and afterwards verified on the ground, or it may be at once laid down on the ground by the use of the chain alone. An improved reflecting instrument, called an optical square, is also often used for this purpose. Any boundaries along the lines or sides of the triangle, ABC, can be determined by the use of offsets or insets, as they occur on right or left of line. No matter what the form of the surface to be surveyed may be—polygon, trapezium, or trapezoid—it may thus be determined by a judicious subdivision into triangles; and when the survey is not of a very extended nature or character, and when no serious obstructions exist, chain surveying is both accurate and expeditious, especially if proof or tie lines are properly introduced for the purpose of testing the accuracy of the work.

In every description of surveying it is best to make the original triangle as large as possible, and to work from a whole downwards rather than build up a large triangle by the addition of several small ones. It would be impossible here to lay down rules to meet the many difficulties which arise in the practice of surveying; indeed the best test of a good surveyor is the ease with which he will overcome local obstructions which appear almost insurmountable to a novice, or even to a theoretical surveyor with little field practice. Where buildings or other impediments are found in the measurement of a straight line, they are generally passed by the erection of short perpendiculars sufficient to clear the obstacles, and a line parallel to the original measured as far as they exist, when the original line can be again resumed. Differences of level occurring in measuring a line where no instruments are used are generally compensated or allowed for by the judgment of the surveyor.

In registering the dimensions taken on the ground, such as sides of triangles, offsets, intersections of roads, fences, &c., and everything necessary to make a perfect delineation or plan of the surface, surveyors use what is called a field-book, the mode of keeping which varies very much with individual practice. Some surveyors use hand sketches or rough outlines of the form of the ground, and mark the dimensions on them, while others use the ordinary form of field-book, or a combination of the two methods, which perhaps is the best when any difficult complications happen on the ground, such as the frequent occurrence of buildings, enclosures, water, &c., along the line. In the ordinary field-book the centre column, commencing from the bottom, represents the length of any line or side of a triangle, and the figures in the column the distance at which the offsets to the right or left are taken, or where roads, streams, fences, &c., cross the line, or buildings adjoin the same. We give herewith the field-book of the assumed survey of the triangle ABC, with the different offsets and insets on its sides, and where roads, fences, streams, &c., cross them, the detail of which can be obtained by subdividing

the triangle into smaller internal ones. The figure can thus be laid down from the book, and its area calculated by the formula $\frac{AB \times CD}{2}$, and the off-

sets and insets calculated, and added or deducted.

Ponds, plantations, and enclosures of different kinds may be surveyed with a chain, especially if their form be such that they can be conveniently included in the area of a triangle, the correctness of which being proved by proper tie-lines, the form, area, &c., may be ascertained by offsets, or rather insets from the sides.

See ORDNANCE SURVEY, LEVELLING, MENSURATION, THEODOLITE, CONTOUR, &c.; and for the United States Coast Survey, see CHART.

Surya, in Hindu Mythology, the sun-god.

Sus, (1) a river and district of Morocco (q.v.), between the Atlas and the Anti-Atlas.—(2) A port (Fr. *Sousse*) of Tunis, 75 miles SE. of the capital. Pop. 20,000.—(3) See SUSA.

Susa, the same as the Shushan of Daniel, Esther, &c., a town of Persia, identified with the modern Sus, anciently the capital of Elam (mod. *Khuzistan*), and one of the most important cities of the old world. Excavation has yielded objects down to 60 metres below ground level, proving that a high civilisation had its seat there. This civilisation appears full grown at Susa, and its origin and date alike are disputed. Some derive it from Egypt; others see in it a source of Egyptian culture and bring it from Central Asia. It has been dated 10,000 B.C. and 4500-4000 B.C. The 'proto-Elamites' were in an age of copper and stone. Their wheel-made thin pottery, painted in lustrous black with geometrical designs and conventionalised animal forms, is of great beauty and shows very great skill. It has since been found at various sites in Mesopotamia. After a period of desertion Susa was again inhabited, this time by Sumerians or kindred folk, who made an inferior pottery, realistic and often polychrome, as well as stone sculptures and cylinder seals. In the 7th century Elam plays its part in history with Assyria (q.v.) and Babylonia (q.v.). After the sack of Susa by Assur-bani-pal, followed by the fall of the Assyrian power, it was brought by Cyrus under Persian rule; and the Achaemenian kings raised it to the dignity of a metropolis of the whole Persian empire, having there a strong citadel and one of their treasure-houses. At the Macedonian conquest Alexander is reported to have found in it vast treasures, together with the regalia. On Babylon becoming the principal city of Alexander and his successors, Susa gradually declined, but seems still to have contained enormous wealth when it fell into the hands of Antigonus (315 B.C.). It was attacked by Molon in his rebellion against Antiochus the Great, and held out bravely for a long time against the Arab invaders at a later date. They, however, destroyed the fortifications. The ruins of the ancient city, the palace described in Esther among them, cover a space of about three square miles. The principal existing remains consist of four spacious artificial platforms above 100 feet high. Traces of a gigantic colonnade were laid bare by Loftus.

See De Morgan, *Mémoires de la déléation en Perse* (1900 et seq.); *The Cambridge Ancient History*.

Susa, a city of Northern Italy, on a tributary of the Po, at the foot of the Cottian Alps, 33 miles by rail W. of Turin. It has a Romanesque cathedral of 1029 (S. Giusto) with a fine brick campanile, together with other interesting mediæval buildings, and a triumphal arch erected by the Romanised Segusian king Cottius to Augustus in 7 B.C. Its importance is largely due to its position guarding the Cenis pass. Pop. (1921) 4594.

Susak, the Yugoslav (Slovenian) suburb of Fiume.

Susannah, HISTORY OF, *The Judgment of Daniel*, also *Susannah and the Elders*, are the different titles of a well-known story, which forms one of three apocryphal additions to the book of Daniel; the other two being *The Song of the Three Holy Children* and *The History of Bel and the Dragon*. It relates how Susannah, the wife of Joacim, and daughter of Hilkiah, celebrated alike for her beauty and her virtue, was falsely accused of adultery by two of the elders, whose own unchaste proposals she had spurned; and how, being condemned to death on their evidence, she was saved by the wise young Daniel, who made the elders confound each other in separate examination, and doomed them to the same fate they had designed for her. In most MSS. this story precedes the first chapter of the Book of Daniel, and so we find it in the old Latin and Arabic versions; but the Septuagint, the Vulgate, the Complutensian Polyglot, and the Hexaplar Syriac place it at the end of the present book, and reckon it as the 13th chapter. There are two Greek versions varying considerably—that of the LXX and that of Theodotion. There is no satisfactory evidence that it ever had a Hebrew or Aramaic original at all. Africans had a controversy with Origen on the authenticity of *Susannah* and *Bel and the Dragon*, and pointed out that their original could only have been a Greek one, as the example of paronomasia in the words of Daniel depended on the Greek. Porphyry based his attack on Daniel partly on the Greek origin of *Susannah*. Jerome is careful to distinguish it from the rest of Daniel, as not possessing the authority of Scripture. At the same time the story is used by Hippolytus, Origen, Tertullian, Ambrose, Gregory Nazianzen, and Chrysostom. The object of the story may have been to correct the procedure of the Sanhedrin, by insisting on the proper use of evidence and the examination of witnesses.

See Kay in Charles's edition of the *Apocrypha* (vol. i. 1913).

Suslik. See ZIZEL.

Suso, Henry (1295–1366), German mystic, was a monk at Constance, and died at Ulm. He was a follower of Eckhart (q.v.).

Suspended Animation, the temporary cessation of the outward signs and of some of the functions of life, is treated under various heads in this work. In men it may be due to Asphyxia, Drowning, Strangulation, &c. See also CATALEPSY, COMA, INSANITY, SLEEP, DEATH, and for premature burial, BURIAL. For phenomena of this kind in the lower animals, see LIFE, DESICCATION, HIBERNATION, LATENT LIFE, ROTIFERA, &c.

Suspension Bridge. See BRIDGE.

Susquehanna, an American river, the North Branch (350 miles) of which has its origin in Schuylar Lake, in central New York, and the West Branch (250 miles) in the Alleghany Mountains. These two unite at Northumberland, Pennsylvania, and the river thence flows south to Harrisburg, and then south-eastward into Maryland, and so to the north end of Chesapeake Bay. Length, 150 miles; chief tributary, the Juniata. It is a shallow, rapid, mountain river, with varied and romantic scenery, and is of use mainly for floating timber. On its banks Coleridge and Southey proposed to found their 'pantisocracy.'

Sussex, a maritime county in the south of England, washed on the south-east and south for 91 miles by the English Channel, and elsewhere bounded by Hampshire, Surrey, and Kent. It has an extremity length from east to west of 76 miles, an extrem

width of 27, and an area of 1455 sq. m. From the Hampshire border, near Petersfield, to Beachy Head (q.v.), 575 feet) the county is traversed by the chalky South Downs, whose highest points in Sussex include Duncton Down (837 feet), Linch Down (818), Ditchling Beacon (813), Harting Beacon (795), and Chanetonbury (783); their steep northern escarpment leads down to the richly wooded Weald, a clay plain. Along the north-east border, from Horsham to Hastings, runs the sandy Forest Ridge (792 feet at Crowborough Beacon). In the extreme north-west a ridge comes from Hindhead, entering Sussex at Blackdown (918 feet, the highest point of the county); on touching Hampshire at Rake it turns eastward past Petworth

the Arun. A very productive tract, 2 to 7 miles road, extends westward from Brighton along the coast to the Hampshire boundary; in the south-east are rich marsh-lands, affording excellent pasture. The chief streams, all unimportant, are the Arun, Adur, Ouse, and Rother. Rather more than two-thirds of the entire area is in cultivation; and the area under woods is greater than in almost any other English county. The Sussex 'Forests' (Dallington, St Leonard's, and especially the largest, Ashdown) are mainly moorland. The Downs (q.v.) are clothed with a short, fine, and delicate turf, and here and elsewhere more than half a million of the well-known Southdown sheep are grazed. Sussex was once the chief seat of the iron trade, when wood was used for smelting, and its last furnace was not blown out till 1809; to-day the manufactures are not important. The county, which contains six 'rapes,' 68 hundreds, and two administrative counties (East and West Sussex), return six members to parliament, four for East, two for West Sussex, besides two for Brighton and one for Hastings. Brighton, Eastbourne, Hastings are county boroughs, and Arundel, Bexhill, Chichester, Lewes, Rye, Hove, and Worthing municipal boroughs; Newhaven, Seaford, Littlehampton, Shoreham, Bognor, Horsham, Petworth also deserve mention. Pop. (1801) 159,471; (1841) 300,075; (1881) 490,505; (1911) 663,378; (1921) 727,996. East Sussex, 532,186; West Sussex, 195,810.

Sussex contains the landing-place, probably not of Caesar (55 B.C.)—for the neighbourhood of Deal is more likely than Pevensey—but of Ælla (477 A.D.) perhaps at Keynor, from whose subjects, the South Saxons, the county derived its name; and of William the Conqueror (1066) at Pevensey, as well as the battlefields of Hastings and Lewes. The antiquities include an ancient camp and flint factory at Cissbury. Roman remains at Pevensey and Bignor, a dozen mediæval castles (Arundel, Bodiam, Hurstmonceux, Hastings, Bramber, &c.), Chichester cathedral (which dates from the 12th century), nine or ten religious houses (Lewes, Battle, &c.), and many interesting churches, mainly along the coast. Cobden, Collins, Fletcher, Otway, Sackville, Selden, and Shelley have been among the eminent natives; Sussex has also memories of Chillingworth, Titus Oates, Hayley, Blake, Lyell, Archdeacon Hare, John Sterling, Manning, Tennyson, and Francis Thompson.

Sustentation Fund. See FREE CHURCH.

Sutherland, a maritime county in the extreme north of Scotland, is bounded W. and N. by the Atlantic, E. by Caithness, SE. by the North Sea, and S. by the Dornoch Firth and by Ross and Cromarty. Measuring 63 by 59 miles, it has an area of 2028 sq. m., or 1,297,914 acres, of which 47,633 are water and 12,812 foreshore. The

Atlantic coasts, deeply indented by sea-lochs, are bold and rock-bound, in Cape Wrath (q.v.) attaining 523 feet; the south-eastern seaboard is comparatively flat. On the Caithness boundary rise the Hill of Orl (1324 feet) and Cnoc an Eireannaich (1698); but the mountains of Sutherland are all in the west—Bannmore Assynt (3273), Coniveall (3234), Bendibrick (3154), Ben Hope (3040), Foinaven (2980), Canisp (2779), and Sullivan or the Sugar-loaf (2399). The Oyckell, tracing the Ross-shire boundary, and falling into the Dornoch Firth, is the longest stream (35 miles); and of over 300 lochs and tarns the largest are Lochs Shin ($16 \times \frac{1}{2}$ miles) and Assynt (q.v., $6\frac{1}{2} \times \frac{1}{2}$). The geology is of great interest—Archaean gneiss predominating in the west, then Silurian, and then Old Red Sandstone. Coal has been mined at Brora off and on since 1573; and attempts have been made since 1868 to work the alluvial gold-field at Kildonan. The total percentage of cultivated area is only 1.7, in spite of costly reclamations carried on by the 3d Duke of Sutherland (1828-92)—so costly indeed that during 1853-82 the expenditure on his estates exceeded the income derived from them by nearly a quarter of a million sterling. The live-stock includes over 10,000 cattle and nearly 200,000 sheep; and the deer forests, grouse-moors, and fishings (especially good for trout) attract many sportsmen. The climate varies much, and also the rainfall, which increases westward from 32 to 60 inches. Sutherland along with Caithness returns one member to parliament; its county town is Dornoch (q.v.). Pop. (1801) 23,117; (1851) 25,793; (1881) 23,370; (1891) 21,896; (1911) 20,179; (1921) 17,802. The Northmen, who to the 12th century often descended on Sutherland and pillaged it, called it the 'Northern land,' as lying to the south of Orkney and Shetland. An earldom of Sutherland was held from about 1228 by the Freskin family, but passed by marriage in 1514 to the Gordons, whose line also ended in an heiress in 1768. She married in 1785 George Granville Leveson-Gower, second Marquess of Sutherland, who in 1833 was created Duke of Sutherland. To him was due the credit or discredit of the so-called 'Sutherland clearances' (1810-20), by which the small tenants, living wretchedly in the interior, were compelled to remove to the coast or to the valleys near the sea.

See Gordon's *Earldom of Sutherland* (1813), Pococke's *Tour* (1888), St John's *Tour in Sutherlandshire* (1849; 1884), Mackenzie's *Highland Clearances* (1883).

Sutherland Falls, near Milford Sound, in the South Island of New Zealand, have a total height of 1904 feet. There are three leaps.

Sutlej, or SATLAJ (anc. *Hypasis*), eastmost of the five rivers of the Punjab, has its genetic source in the Ganglung Glacier in Tibet, about 20 miles from the Brahmaputra Glacier, and flows into Lake Manasarowar, or Mansarowar (q.v.). Sven Hedin's explorations in 1901-2 shed much light on its upper course. Its passage into and out of Lake Rakas-tal is now no more underground, owing to silting of the channels and a fall in the level of the lakes. It flows at first north-west, but turns westward to cut its way through the Himalaya Mountains, in the course of which passage it drops to about 3000 feet. After entering British territory it pursues a general south-western direction, receives the Li or river of Spit, passes round the Siwalik Hills, picks up the waters of the Beas and the Jhelum-Chenab, and, after flowing 900 miles in all, joins the Indus at Mithankot, south of Multan. Not far from Jullundur it is crossed by a magnificent iron bridge, 5200 feet long, carrying the Sind, Pnnjab, and Delhi Railway, and near Bhawalpur, just before its

confluence with the Jhelum-Chenab, is spanned by the bridge of the Indus Valley Railway. A great scheme is on foot in the Sutlej Valley for the irrigation of some 14,000 square miles, whereof the first unit came into use in 1926.

Sutler. See CAMP FOLLOWERS.

Sūtra, in Sanskrit Literature, the technical name of aphoristic rules, and of works consisting of such rules. In such aphorisms the ground-works of the ritual, legal, grammatical, metrical, and philosophical literature of India are written. See SANSKRIT, VEDA, PĪṬAKA.

Suttee (an English spelling of the Sanskrit *sati*, 'a virtuous wife'), a usage long prevalent in India, in accordance with which on the death of her husband the faithful widow burned herself on the funeral pyre along with her husband's body, or, if he died at a distance, was burned on a pyre of her own. The practice was in use in India as early as the times of the Macedonian Greeks, and was based by Hindus on various of their sacred books and laws (the *Brahma-Purāṇa*, the *Yājñasmyiti*, &c.). But the researches of European scholars have made it absolutely certain that no countenance to this barbarous rite can be derived from the oldest and most sacred scriptures. The few passages professedly cited from the Vedas have been proved to be misquoted, garbled, or wholly false; and the laws of Manu are silent on the subject. Nevertheless self-immolation, though not in theory enforced on an unwilling victim, or one enfeebled, and not practised except in certain castes and families of old descent, was almost made inalienable on well-born widows by force of public opinion, unless they were willing to risk their own happiness hereafter, and to live on a life of utter degradation and misery. The rite was no doubt derived from a belief common to many races at all times of the world's history, that it was well to send wives, slaves, horses, favourite weapons, &c., along with a great man into the other world, by burying them with him, burning or slaying them at his tomb. The Vedic evidence shows that the Brahmans disliked the practice, and transformed the older usage by reducing the rite to a form, the wife lying indeed on the pyre beside the dead, but being hidden to arise to the world of the living, and to be taken in marriage by a brother of the dead man. Later, however, the older practice evidently regained its position in popular favour, and was doubtless promoted in royal families by the inconvenience of maintaining the wives—often numbering scores—of dead kings. Holocausts of such victims are recorded in the kingdoms of Southern India in the period after the Mohammedan invasions. In 1823 there were 575 widows burned in Bengal Presidency, 310 within the jurisdiction of the Calcutta Court. Of these 109 were above sixty years of age, 226 from forty to sixty, 208 from twenty to forty, and 32 under twenty (Max-Müller, *Biographical Essays*, 1884). When Lord William Bentinck resolved to put an end to this hideous sacrifice he was met by fierce opposition both from natives and Europeans, though backed by some official and public opinion. And on the 4th December 1829 he carried the regulation in council which made all who encouraged suttee guilty of culpable homicide. The enactment soon took on the custom. The prohibition of suttee is a feature of treaties between the imperial government and the Indian states; and though occasional cases of suttee occur in the territory of the Indian states, and rarely within the British area (on the death of Sir Jung Bahadur, prime-minister of Nepal, in 1877 several of his wives immolated themselves), suttee may be said to be practically extinct.

Suttner, BARONESS BERTHA VON (1843-1914),

Austrian writer, was born at Prague, a daughter of Count Franz Kinsky. She travelled extensively, was the author of *Die Waffen Nieder* (1889) and other novels, published books on international affairs, was for a time secretary to Alfred Nobel, presided at many peace congresses, and in 1905 was awarded the Nobel prize for peace.

Sutton, a town and urban district in Surrey, 11 miles from London. Pop. (1921) 21,065.

Sutton Coldfield, a municipal borough of Warwickshire, 8 miles NE. of Birmingham, and practically a residential suburb and health resort of that city. Sutton Park, owned by the corporation, is a natural wooded park of more than 2000 acres, with facilities for boating and bathing. In it can still be seen a long stretch of Ryknield Street (sometimes referred to as Icknield), one of the best remaining examples of a Roman highway in this country. Seized by William the Conqueror in 1071, the town remained a royal manor until 1126. Through the influence of John Vesey, Bishop of Exeter, Henry VIII granted, in 1528, a charter (still in the corporation's possession) giving the town amongst other privileges the title of the Royal Town of Sutton Coldfield. The powers granted led to constant litigation and several commissions, resulting in a modern charter in 1886. Vesey founded the grammar school in 1541, and was buried in the parish church, which was built in the 14th century; Vesey restoring the tower in 1533. Since then the church has been considerably altered, a new aisle being added in 1880. Municipal charities have an income of more than £3000 per annum. It forms part of the parliamentary division of Tamworth. Pop. (1901) 14,264; (1911) 20,132; (1921) 23,020. See Midgley's *Short History of the Town and Chase of Sutton Coldfield* (1904).

Sutton-in-Ashfield, a town of Nottinghamshire, 3 miles SW. of Mansfield. It has a fine church (1300; restored 1868), hosiery manufactures, and neighbouring coal pits and lime-works. Pop (1921) 23,852.

Sutton-on-Sea, a seaside resort on the coast of Lincolnshire, much frequented by the people of the big towns of Nottingham, York, Lancaster, and Leicester, is 28 miles NE. of Boston by rail. It has a fine stretch of broad, firm sand, and close by a submerged forest may be seen at low tide.

Suture (Lat. *sutura*, 'a seam') is a term employed both in Anatomy and Surgery. In anatomy it is used to designate the modes of connection between the various bones of the cranium and face. A suture is said to be *serrated* when it is formed by the union of two edges of bone with projections and indentations (like the edge of a saw) fitting into one another. The coronal, sagittal, and lambdoidal sutures (see SKULL) are of this kind. A suture is termed *scutaneous* when it is formed by the overlapping of the bevelled (or scale-like) edges of two contiguous bones.

In surgery the word suture is employed to designate various modes of sewing up wounds, so as to maintain the opposed surfaces in contact. The materials most commonly used are silk, silver wire, horsehair, and specially prepared catgut. As it may fall to the lot of any person, on an emergency, to have to sew up a wound, the following general rules, applicable to all forms of suture, should be attended to. In passing the needle, the edges of the wound should be held in contact with the forefinger and thumb of the left hand; and the needle should penetrate the surface at about an angle of 50° (rather more than half a right angle), and should, at least, pass through the whole thickness of the skin at each stitch. The distance from the edge of the wound at which each stitch should

enter and leave the skin must vary with the depth of the wound; but there should never be less than the eighth of an inch between the margin of the wound and the entrance or exit of the needle.

Fig. 1.

Sutures should not include vessels, nerves, muscles, or tendons. The line of the thread should cross that of the wound at right angles. For incised wounds on the surface of the body, when the edges can only be transfixed from the cutaneous surface, or when the opposite margins can both be traversed by one plunge, a curved needle (such as a common packing-needle) is most convenient, whereas a strong straight needle is more convenient for the completely free margins of extensive wounds, such as are left after amputation.

Fig. 1 represents various forms of needles used by surgeons; fig. 2 shows the *twisted suture*, as used in the operation for harelip, in which the wound is transfixed by pins, around which, beginning with the uppermost, a thread is twisted, in the form of the figure 8.

Fig. 2.

Suvóroff, or SUWARROW, ALEXANDER VASILIEVITCH, a Russian general, was born at Moscow on 24th November 1730, his father, of Swedish descent, being a general and senator. Small of stature and sickly in appearance, Alexander was a devoted student, and whilst still a boy acquired an excellent knowledge of languages; but his heart was fired with the passion of military glory, Caesar and Charles XII. of Sweden being the heroes of his imagination. Enrolled in the army at twelve, he began his actual service as a private at fifteen, but advanced rapidly in rank after the Seven Years' War, in which he greatly distinguished himself at Kunersdorf (1759) and Reichenbach (1761), and after the Polish war of 1768-71, in which his impetuous bravery, and the boldness and celerity of his attack, brought him prominently forward. From this time to the end of his life he was almost constantly in the field. In 1773 he passed from Poland to the south of Russia to war against the Turks; in 1774 he put an end to the insurrection of Pugatcheff; and in 1780 he crushed the revolt of the Kaban Tatars and other Caucasian tribes. He covered himself with glory in the Second Turkish War, defeating the armies of the sultan at Fokshani (1789) and at the river Rymnik, and storming the strong fortress of Ismail. In the Polish war of 1794 Suvóroff captured Praga, and so compelled the surrender of Warsaw. On the accession of the Emperor Paul he was for a time sent into retirement; but shortly afterwards Paul recalled him and ordered him (1799) to Italy to assist the Austrians in opposing the French. As usual he

won battles, defeating Moreau on the Adda, MacDonald at the Trebbia, and Joubert at Novi. Then he was directed to cross the Alps and unite his forces with Korsakoff for the purpose of sweeping the French out of Switzerland. After a terrible march, with fearful sufferings and heavy losses, he found, on descending towards the canton of Schwyz, that Muscena had defeated Korsakoff, and being himself too weak to attack he barely managed to escape over the mountains into Austria. On his return to Russia he was overtaken by death at St Petersburg on 18th May 1800. Suwóroff was a little man (5 feet 4 inches), with a wrinkled face and a stooping attitude; yet he was strong and healthy, and inured to hardship—he lived like a common soldier, and slept by preference on a truss of hay. Of great intelligence, he was a constant reader, even when on campaign, and a clever linguist. The idol of his soldiers, who loved to call him 'Father Suwóroff,' he was never defeated, and only once in his life acted on the defensive. He had a superb faith in his own star, and trusted to the inspiration of the moment, to rapidity of movement, and to boldness and dash in making the onset. Notwithstanding the terrible loss of life that attended his storm of Ismail (26,000 Turks were killed) and of Praga at Warsaw (where 15,000 Poles were massacred), he is stated to have been averse to shed blood, and to have been even humane and merciful. In his manners he was extravagantly eccentric, brusque and curt in speech, laconic in his despatches, and sarcastic to all who incurred the contempt of the soldier and man of action. Byron's description of him in *Don Juan* is as inaccurate as the biographies written by his enemies, the French. See *Lives* by Spalding (1890), and W. L. Bleasde (1920).

Suwałki, a town of northern Poland in the north corner of Białystok, 48 miles NW. of Grodno, has lumber and agricultural trade. Pop. (1921) 16,780.

Suwanee River rises in southern Georgia, in the Okefenokee Swamp, and flows in a winding, generally south-south-west course through Florida into the Gulf of Mexico.

Suzdal, a small Russian town, 12 miles N. of Vladimir, once capital of an important Russian principality.

Suzerain, a feudal lord. The term was applied less to the king than to his vassals who had sub-vassals holding of them. In modern times suzerainty indicates a degree of formal or real authority varying within a wide range.

Svalbard. See SPITSBERGEN.

Svastika, a widespread religious symbol. It consists of a Greek cross, either enclosed in a circle the circumference of which passes through its extremities ⊕, or with its arms bent thus

卐 or 卐, and according to some was intended to represent the sun, being found associated with the worship of Aryan sun gods (Apollo, Olin). Similar devices occur on the monumental remains of the ancient Mexicans and Peruvians, on objects from the burial mounds of the United States and in Tibet. A Svastika with its toes turned the wrong way, seeming to go contrary to the diurnal course of the sun, is sometimes regarded as wicked or of evil omen. The name *fylfot* which probably arose from a blunder, is by some appropriated to the reversed Svastika. In Germany the Svastika or Hakenkreuz, has been taken as a badge by the anti-Semites, 'Hakenkreuz am Stahlhelm' their slogan. See CROSS; T. Wilson, *The Svastika* (1898).

Sveåborg, or SUOMENLINNA, a fortress protecting Helsingfors (q.v.).

Svealand. See SWEDEN, p. 803.

Svendborg. See FÜNEN.

Svendson, JOHAN SEVERIN, composer, born at Christiansia, 30th September 1840. He studied at Leipzig, Paris, and in Italy, conducted concerts in his native town, and in 1883 became master of the Chapel Royal at Copenhagen. His works comprise symphonies, an overture, and quartets, quintets, and concertos for strings. He died 14th June 1911.

Svenigorodka, a town in Ukraine, 100 miles S. of Kieff. Pop. (1920) 38,713.

Sverdlovsk, the new name of Ekaterinburg.

Sverdrup, OTTO, Norwegian explorer, born in 1855 in Helgeland, co-operated with Nansen on several Arctic voyages.

Swabia (Ger. *Schwaben*), or SWABIA, an ancient duchy in the south west of Germany, stretching from Franconia to Helvetia (Switzerland) and from Burgundy and Lorraine to Bavaria. It was so named from the Germanic Suevi, who drove out the Celtic inhabitants of the region in the 1st century B.C. With those conquerors the Alemanni, who invaded that part of Europe in the end of the 5th century, became amalgamated; and from that time there were dukes in Swabia, except for the period 746-919. During the reigns of the Hohenstaufen emperors, who were natives of Swabia and almost invariably conferred the ducal dignity on some relative of their own house, this duchy was the most rich, most civilised, and most powerful country of Germany, and the ducal court was the centre of art, literature, and learning. After the extinction of the imperial Swabian (Hohenstaufen) line the dignity of duke of Swabia remained in abeyance; the feudatories of the duchy asserted an immediate dependence upon the empire, and waged frequent wars one upon another. Of these minor states the most important and most powerful were the countships of Württemberg and Baden. The towns and cities, very many of which enjoyed the freedom of the empire, preserved a strong feeling for independence and a no less strong feeling of opposition to the feudal lords. In 1331 twenty-two towns (Ulm, Reutlingen, Augsburg, Heilbronn, &c.) united for purposes of mutual defence. Thirty years later many of the minor feudal lords formed a league to oppose the towns, and bloody feuds arose between the parties. The league of the feudal party was broken up by the Count of Württemberg, the ally of the Swabian league (of towns), in the last years of the 14th century. Nevertheless feuds and violent dissensions still raged rampant, and even continued to do so after the emperor summoned all the parties concerned to a conference at Esslingen (1487), where the Swabian League was formed (1488) for the maintenance of peace throughout the old Swabian duchy. This unhappy region suffered terribly during the Peasant War (q.v.) of 1525, in the Thirty Years' War (1618-48), and during the wars of the French Revolution. It formed one of the ten circles of the empire until the dissolution of the latter after Ansterlitz, when Napoleon increased the territories of Baden and Württemberg by dividing between them the Austrian possessions in Swabia, at the same time raising the Duke of Württemberg to the status of king.

The *Swabian School*, in German literature, indicates a band of writers who were natives of Swabia (as Uhland, Schwab, Kerner, Mörike, Hauff, and others). For the *Swabian Alb*, see WÜRTTEMBERG.

Swadeshi (Bengali, 'own country'), a movement in India dating from about 1905, for boycotting foreign goods.

Swaffham, a market-town of Norfolk, 15 miles SE. of Lynn. It has a cruciform Perpendicular

church (1474) of great beauty, a corn-hall (1858), and an ugly market-cross (1783). Pop. (1851) 3858; (1921) 2913.

Swahili (Arab. *Waswāchili*, 'coast people'), the name given to the people of Zanzibar and the opposite coast belonging to the Bantu stock, with an Arab infusion, and speaking Kiswahili, a Bantu tongue modified by Arabic. The Swahili are intelligent and enterprising, and are in demand as porters by travellers into Central Africa. There are various collections of Swahili folk-tales, a handbook by Bishop Steere, and dictionaries (1902-3), and grammar (1921) by Madun.

Swale, a river in the North Riding of Yorkshire, flowing 60 miles ESE., and near Aldborough uniting with the Ure to form the Ouse (q.v.).

Swallow, a genus (*Hirundo*) and family (Hirundinidae) of Passerine birds. The members of this family are distinguished by their long and pointed wings, long head, slender wide bill, small legs and feet, tarsus scutellated in front, and tail generally forked. They have no autumn moult, but acquire their new dress in February; hence Seebohm thinks they are a recent import from the south which, like some shrikes, have changed their breeding time, but have not yet altered their moulting time. The genus *Hirundo* is cosmopolitan in distribution, and contains about sixty species. The members are gregarious, and prefer well-cultivated districts and the proximity of water. They have great powers of flight and perch but little, catching their prey, which consists chiefly of insects, on the wing. Their usual

the breast glossy bluish black, the forehead and throat chestnut, the lower parts white, and a patch of white on the inner web of each of the tail-feathers except the two middle ones. The whole length of the bird is about 8 inches, of which the outer tail-feathers make 5 inches. The female has a shorter tail, less chestnut on the forehead, and whiter under parts. The nest, probably originally built in caves, is made of mud or clay, formed into little pellets and stuck together, along with straw and bents, and lined with feathers. It is open and cup-shaped, and is generally placed in a situation where it is sheltered from wind and rain, as a few feet down an unused chimney, under the roof of an open shed, or in any unoccupied building to which access can be obtained. From four to six eggs are laid, blotched and speckled with shades of gray and brown. Two broods are produced in a year. Large flocks collect together in autumn before they depart for the south. Some individuals have been found in Britain in December, and may even survive a mild winter. A long-lived popular delusion credited swallows with hibernating regularly under water. The Window-swallow, or House-martin (*H. urbica*, or *Chelidon urbica*), is another very common British species, glossy bluish black above, white below and on the rump; the feet covered with short, downy white feathers. Its length is a little over 5 inches; the sexes are alike in plumage. The nest is built of mud or clay, like that of the chimney-swallow, but is hemispherical, with the entrance on the side, and is attached to a rock, or, very frequently, to the wall of a house, under the eaves or in the upper angle of a window. Two or even three broods are produced in a season, and the old birds return year after year to nest in the same spot. House-martins congregate in great numbers, as the chimney-swallows do, before their autumn migration, and disappear all at once. The only other common British species of swallow is the Sand-martin (*H. riparia*), smaller than the two preceding and arriving before them. It has the toes naked, the tail moderately forked, the plumage brown on the upper parts and across the breast, the under parts white. It makes its nest in sandy river-banks, the sides of sand-pits, and other such situations (even the turf-covered roofs of peasants' houses in Norway), excavating a gallery of 18 inches or 2 feet, sometimes 3 or even 5 feet in length, and more or less tortuous, in the

Fig. 1.—a, Common Swallow (*Hirundo rustica*); b, House-martin (*H. urbica*).

note is a twitter, but some species sing sweetly. Their nests are built of mud, straw, and feathers, on ledges under eaves, on rocks, in caves, and in holes in earthy cliffs. Five species are found in Europe, and three are migrants to the British Isles. The Common Swallow, or Chimney-swallow (*Hirundo rustica*), is distributed in Europe, Asia, and Africa, from Lapland to the Cape of Good Hope and to the Moluccas. It breeds in the Orkney and Shetland Islands, and straggles to Iceland, Spitsbergen, and Novaya Zemlya, but does not reach America. It exhibits a character common to many other species, in the very long and deeply forked tail, the two lateral feathers of which far exceed the others in length. The plumage is very beautiful, the upper parts and a band across

Fig. 2.—Sand-martin (*Hirundo riparia*).

slightly dilated extremity of which some soft material is placed for the reception of the eggs. This wonderful excavation is accomplished entirely by the bill of the bird. The floor slopes a little upwards from the entrance, so that the lodgment of rain is prevented. The sand-martin, on account of the nature of its haunts, is somewhat more local than the other British swallows; but it is distributed over most parts of Europe, Asia, Africa, North America, and South America to the Amazon valley. The Purple Swallow, or Purple Martin (*H. or Progne*

purpurea), is a North American species, which is said to have visited the British islands. The general colour, both of the upper and under parts, is shining purplish blue; the wings and tail black. It abounds in North America, and is a universal favourite in the northern parts, being hailed as the harbinger of spring, and frequenting even the streets of towns. It is a very general practice to place boxes near houses for the martins to make their nests in, which are very inartificial, consisting merely of dried grass, leaves, moss, feathers, and the like. Boxes nailed to trees are also readily occupied by the Rufous-bellied Swallow (*H. erythrogaster*), another North American species. But this species, which very nearly resembles the chimney-swallow of Britain, makes a nest of mud and fine hay, in the form of the half of an inverted cone, with an extension at the top, for one of the parent birds to sit in occasionally. The Republican Swallow, or Cliff-swallow (*Petrochelidon lunifrons*), of North America, makes a nest of mud, in form somewhat like a Florence flask, which it attaches to a rock or to the wall of a house. Hundreds sometimes build their nests in close proximity. The Fairy-martin (*H. ariel*), a small Australian species, also builds a flask-shaped nest with the mouth below, attaching it to a rock, or to the wall of a house; and numerous nests are often built close together. Another Australian species (*Petrochelidon nigricans*) lays its eggs in a hollow tree or rock without any nesting material. Some of the swallows of tropical countries are much smaller than any of the European species. See SWIFT.

Swammerdam. JAN, entomologist and anatomist, born at Amsterdam, 12th February 1637, showed almost from his boyhood the greatest zeal in the study of natural history. Choosing medicine for his profession, he was trained at Leyden, and settled down to practise in Amsterdam. But he gave far more time and attention to investigating the life-history and anatomical structures of insects than to his calling, became straitened for means, and finally was carried away by the religious mysticism of Antoinette Bourignon (q.v.). He died at Amsterdam on 17th February 1680. His chief services in the advancement of science were the application of a method of studying the circulatory system by injections of hot wax, demonstrations in the anatomy of bees and other insects, and investigations into the metamorphoses of insects, the results of which afforded sure groundwork for subsequent classification. His most important books were *General Treatise on Bloodless Animals* (in Dutch, Utrecht, 1669) and *Biblia Naturæ* (ed. Boerhaave, 1737-38), giving the results of his researches in insect anatomy.

Swan (*Cygnus*), a genus of birds constituting a very distinct section of the Duck (q.v.) family Anatidae. They have a bill about as long as the head, of equal breadth throughout, higher than wide at the base, with a soft core, the nostrils placed about the middle; the neck longer than the body, arched, and with twenty-three vertebrae; the legs short and placed far back; the front toes fully webbed, the hind toe without membrane; the keel of the breast-bone very large; the intestines very long, and with very long caeca. They feed chiefly on vegetable substances, as the seeds and roots of aquatic plants, but also on fish spawn, of which they are great destroyers. They are the largest of the Anatidae. They have a hissing note like geese, which they emit when offended, and they deal tremendous blows with their wings in attack or defence. The Common Swan, Mute Swan, or Tame Swan (*C. olor*) is about 5 feet in entire

length, and weighs about 30 lb. It is known to live for at least fifty years. The male is larger than the female. The adults of both sexes are pure white, with a reddish bill; the young (cygnets) have a dark bluish-gray plumage and lead-coloured bill. The bill is surmounted by a black knob at the base of the upper mandible, and has a black nail at its tip. In its wild state this species is found in the eastern parts of Europe and in Asia as far as Mongolia and the north-west of India, breeding in Denmark, the south of Sweden, in central and southern Russia, and in Turkestan; in a half-domesticated state it has long been a common ornament of ponds, lakes, and rivers in all parts of Europe. It is said to have been brought to England from Cyprus by Richard I. It is perhaps the most beautiful of water-birds, when seen swimming, with wings partially elevated, as if to catch the wind, and finely-curved neck. The ancients called the swan the Bird of Apollo or of Orpheus, and ascribed to it remarkable musical powers, which it was supposed to exercise particularly when its death approached. The note of the male bird at breeding time is loud and trumpet-like; the tame bird's note is little more than a hiss. The nest of the swan is a large mass of reeds and rushes, near the edge of the water, an islet being generally preferred. The female begins as a rule to lay in her second year from three to five eggs; when older she lays ten to twelve eggs, of a dull greenish-white colour. These birds are said to pair for life. The female swan sometimes swims about with the unfledged young on her back; and the young continue with their parents till the next spring. The swan is now seldom used in Britain as an article of food, but in former times it was served up at every great feast, and old books are very particular in directions how to roast it and to prepare proper gravy. The Polish swan (*C. immutabilis* of Yarell) is generally believed now to be a mere variety of the common swan. The Whistling Swan, Elk Swan, or Whooper (*C. ferus* or *musius*) abounds

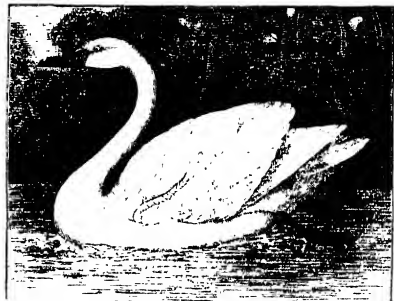

Fig. 1.—Wild Swan, or Whooper (*Cygnus ferus*).

in the northern parts of Europe and Asia, but to Britain it is now merely a cold-season migrant from more northern regions, although about a century ago it used to breed in the Orkneys. The size is about equal to that of the common swan, and the colour is similar, but the bill is more slender, is destitute of a knob, and is depressed and black at the tip and yellow at the base. This bird is frequently brought to the London market. The names whooper and whistling swan are derived from the voice. Like all swans of the northern hemisphere, except the common swan, this one has a large cavity in the interior of the breast-bone in which the windpipe coils before passing to the lungs. Bewick's Swan (*C. bewicki*), another native

of northern Europe, is more rare in Britain, but large flocks are sometimes seen. It is about one-third smaller than the whistling swan. The American swan (*C. americanus*), closely resembling Bewick's swan but larger, is sometimes found in Britain. It breeds in the northern parts of North America, but its winter migrations extend only to North Carolina. The Trumpeter Swan (*C. buccinator*) is another American species, breeding chiefly within the Arctic Circle, but of which large flocks may be seen in winter as far south as Texas. It is rather smaller than the common swan. The ancients spoke of a black swan proverbially as a thing of which the existence was not to be supposed, but Australia produces a Black Swan (*C. atratus*), discovered towards the end of the 18th century, rather smaller than the common swan, the plumage deep black, except the primaries of the wings, which are white. The neck is long, thin, and gracefully curved. The eye is red. The bill is vivid carmine, with a white cross band. It has been entirely acclimatised in the northern hemisphere. The Black-necked Swan (*C. nigricollis*), perhaps the handsomest bird of the genus, is a

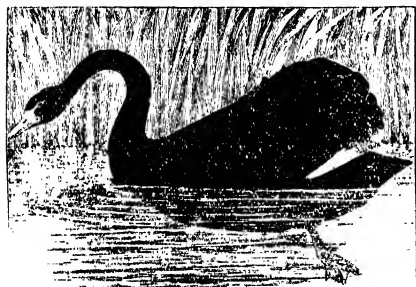

Fig. 2. Black Swan (*Cygnus atratus*).

South American species, ranging from Chile to the Falkland Islands. The Duck-billed swan (*C. anatinoides*), the smallest of all the species, common about the Strait of Magellan, has the head and neck dark brown, and the rest of the plumage of the purest white. It is curious that the black colour appears in all the species of the southern hemisphere, and in them alone, except in the approach to it made in the cygnets of the north.

Swans, according to the law of England, are birds-royal. When they are found in a partially wild state, on the sea and navigable rivers, they are presumed to belong to the crown. The royal birds generally have a 'nick' or mark on them, and the king's swanherd once was an important person. But any person may have tame swans in his grounds, and then he has a property in them. Whoever steals or destroys swans' eggs forfeits 5s. for every egg, and whoever steals a marked swan of the crown, or a tame swan, commits felony. The most famous swannery is that of Abbotsbury in Dorsetshire, 8 miles NW. of Weymouth, though the number of its swans has diminished.

SWAN, ANNIE S. (MRS BURNETT SMITH), daughter of a farmer at Gorebridge, Midlothian, a prolific writer of tales and magazine stories.

SWAN, SIR JOSEPH WILSON, F.R.S. (1828-1914), best known as the inventor of an incandescent electric lamp, was born in Sunderland. The dry plate process and other photographic methods owe much to his inventive genius. He also devised a miner's electric safety-lamp, and improved methods of electro-metallurgical deposition. He was knighted in 1904.

Swanage, a pleasant little watering-place of Dorsetshire, in the 'Isle' of Purbeck, nestling in the southern curve of a lovely bay, 9½ miles SE. of Wareham, but 11 by rail (1885). In Swanage Bay, in 877, King Alfred won England's first naval victory—a defeat of the Danes. Pop. (1921) 7112. See **PURBECK**.

Swansea (Welsh *Abertawe*), a seaport of Glamorganshire, South Wales, on the banks and at the mouth of the river Tawe, 45 miles WNW. of Cardiff and 216 W. of London. A municipal, parliamentary, and also (since 1888) county borough. It owes its rapid progress after 1850 to the manufacture of tin-plate here and in the neighbourhood, and to its harbour and docks. There are five docks, North, South, Prince of Wales, King's, and Queen's; the King's Dock has an area of 221 acres, and there are over 6 miles of quays. There are large manufactures of iron, zinc, lead, copper, silver, tin, &c., and in the 20th century oil refining has become very important. The tin-plate industry of Swansea is supposed to be one of the largest in the world. The principal exports are coals, anthracite, copper, and tin, chemical, iron (including tin plate), and cotton manufactures. The chief imports are crude oil from Abadan, for the National Oil Refinery at Llandarcy, about five miles from Swansea, whence the oil is pumped from the incoming tankers, corn, copper and iron ore, petroleum, sugar, potatoes, onions, and wood. Pop. of municipal borough (1851) 31,461; (1891) 90,423; (1911) 143,997; (1921) 157,561. Since 1918 the town returns two members, for the east and west divisions respectively. Swansea was originally probably a Scandinavian settlement. The castle, of which a tower still remains, was founded in 1106 by the Earl of Warwick, but in the reign of Edward IV. passed by marriage from the Herberts to the Somerset family, and is still the property of the Dukes of Beaufort. The Parish Church of St Mary, dating from the 12th century, was finally rebuilt by Bloomfield in 1897. Since 1923, when the diocese of St David's was divided, Swansea has been part of the diocese of Swansea and Brecon. The Royal Institution of South Wales contains a library, art gallery, and museum with an Egyptian collection, and a magnificent department of British birds. Swansea also has a Public Library and Institute of Science and Art. The grammar-school dates from 1682. In 1920 the foundation stone was laid of the Swansea University College, incorporated as a constituent college of the University of Wales. Bishop Gower (d. 1347) and Beau Nash (1674-1762) were natives.

See works by L. W. Dillwyn (1840), G. G. Francis (1849-67), P. Rogers (1878), L. C. Martin (1879), and F. Grant (1881); *Histories of Swansea* (1920) and of the Port of Swansea (1922) by W. H. Jones; and the articles **COPPER** and **TIN**.

Swanwick, **ANNA** (1813-99), was born at Liverpool, studied Greek and Hebrew in Berlin, mathematics in London, and interested herself in women's education and philanthropy. She translated from Goethe, Schiller, and Æschylus. See **Study** by Bruce (1903).

Swastika. See **SVASTIKA**.

Swat, a river in Kafiristan (q.v.), joining the Kabul River near Peshawar. In 1897 the 'Mad Mullah,' proclaiming himself the successor by divine selection of the Akhund of Swat, who died in high reputation about 1878, roused the tribes inhabiting the Swat valley to a holy war against the infidels. They attacked the British camp at

Malakand, but were repulsed. The disturbance, however, spread through the neighbouring tribes, including the Bunnars, Waziris, Urakzais, and Afridis, and resulted in the frontier war which terminated with the brilliant engagement at Dargai, 20th October 1897.

Swatow, a seaport of China, which has been opened to foreign trade since 1869, stands at the mouth of the river Han, 225 miles E. of Canton, in the province of Kwang-tung. It is the seat of great sugar-refineries and bean-cake and grass-cloth manufactures, and has an important shipping trade. The chief exports are sugar, tobacco, grass-cloth, cloth and nankeen, and tea. Pop. 83,000.

Swaziland, a South African territory, lying on the west side of the Libombia Mountains, and forming an intrusion into the south-east of the Transvaal. It has an area of 6678 sq. m., and according to the census of 1921, a population of 133,563 (including 2200 Europeans). Cotton and maize are grown, and there is a considerable amount of cattle and sheep grazing, but the rich mineral resources (tin, gold, &c.) have not nearly been exploited to their full extent. For customs purposes, Swaziland is treated as part of the Union of South Africa. The seat of government is at Mbabane. The independence of this little state was recognised by its powerful neighbours, the South African Republic and the British government, in 1894: the white settlers, mainly gold-miners, were put in 1899 under a joint 'government committee' appointed by Britain and the Boers, and in 1895 under the protection of the Republic. Authority over Swaziland was given in 1903 to the Governor of the Transvaal, and in 1906 to the High Commissioner for South Africa.

Swearing, or PROFANE SWEARING, the habit of using the name or attributes of God in a light and familiar manner by way of asseveration or emphasis. It was specially condemned by the Moslem law, was long punished by severe penalties, and is still an actionable offence in England. By oaths are loosely understood also many terms and phrases of gross and obscene character. There is a legitimate use for solemn cursing; but weak men of limited vocabulary, under the pressure of excitement, seek for artificial strength or verification by employing irrelevant words that carry with them ideas of gravity or strength. Senfaring men and persons in command generally often use such expressions to add weight to their words, and some apology may be found for them in the fact that the persons with whom they have usually to deal have been so accustomed to their use as not to be readily inclined to obedience without them. Again, other and more imaginative men from the days of Rabelais until now garnish their talk with oaths as a mere exercise of verbal ingenuity, or by way of set off to their conversation.—'How now?' said Poncecrates; 'you swear, Friar John.' 'It is only,' said the monk, 'but to grace and adorn my speech; they are colours of a Ciceronian rhetoric.'

To call God to witness is a thing natural enough on occasions of grave asseveration, as in giving witness in courts of law and the like, and it has been from the beginning a custom to take oaths on things sacred or august, as the head of the emperor, the beard of the Prophet, the sword blade or hilt, and the gospels. Thomas Becket denounced John the Marshal of England for swearing on the *trovarium*, a collection of verses and sequences used in the service of the mass. We find oaths frequent enough among the Greeks and Romans: Pythagoras is said to have sworn by the number four; Zeno, by the caper; Socrates used mild oaths, as 'By the dog,' and Aristophanes tells of a time when no men swore by the gods, but all

by birds. The Romans used 'Mehercule,' 'Medius Fidius,' 'Edepol,' 'Ecastor,' and 'Mecastor' (properly a woman's oath), &c. Brantôme tells us Louis XI. said 'Par la Pâque Dieu,' the oath of Francis I. was characteristic—'Foi de gentil-homme.' 'Ventre Saint Gris,' again, was one of the Gascon oaths of Henry IV. of France, which he alternated with another favourite, 'Jarniden.' Many of the modern French oaths, as 'Parbleu' (*par Dieu*), 'Corbleu' (*corps de Dieu*), 'Ventrebleu,' and 'Sacrebleu,' are illustrations of a process of softening an oath by a deliberate disguise, like the old-fashioned 'Gad' and 'Egad,' the north country 'Dod' and 'Sensh' (*God's curse*), and the older English 'Slight' (*God's light*), 'Od's fish'—the usual oath of Charles II., 'Zounds' (*God's wounds*), 'Od's bodikins,' and the American 'Darn.' Similarly in Italy, between the severe laws against profanity and blasphemy and the necessity of confession, forms like 'Per Dio' became in early times disguised as 'Per Dinci.' Indeed the Italians, especially in Tuscany, are extraordinarily rich in oaths, many strange and grotesque forms being in use, and the meanings of common forms being carefully differentiated. Mr Story tells us that 'Dio mio' is proper as an expression of sudden surprise, 'Madonna mia' of pity and sorrow, 'Per Christo' of hatred and revenge. Nothing on the Continent strikes an English ear more strangely than the familiar use of 'Dien' in France and of such phrases as 'Herr Je' in Germany, and English reticence refuses to accept the over-subtle apology even of a Cardinal Newman (*Lect. on Certain Diffic.* ix.), that this variety and fertility in adjurations and invocations is merely because a Catholic populace has a greater insight into the unseen world than a Protestant. 'The Catholic's very jesting, and his very oaths, have been overuled,' says he, 'to create in him a habit of faith, guarding round and protecting the supernatural principle.' But it is proper to explain that what James Howell calls 'this invidious custom of swearing' is to Continentals specially an English characteristic. Indeed Howell himself, after enumerating the performances of the German, the Italian, the Frenchman, the Spaniard, the Welshman, the Irishman, and the Scot, admits that 'for variety of oaths the English Rovers put down all.' Byron describes how Don Juan on his first arrival in England is rudely awakened from the innocent belief that 'their shibboleth "God damn"' is a usual salutation. Beaumarchais (*Le Mariage de Figaro*, iii. 5) says, 'Avec Goddam en Angleterre on ne manque de rien nulle part . . . les Anglais à la vérité ajoutent par-ci par-là quelques autres mots en conversant; mais il est bien aisé de voir que Goddam est le fond de la langue.' We hear this phrase as a synonym for Englishman even from the pure lips of Joan of Arc, and we certainly find the oath in the other Elizabethan dramatists, and in Shakespeare, but not in anything like its modern pre-eminence of importance. Still we find oaths enough of all shades of profanity in early English literature, and corresponding denunciations in the writings of preachers like Jeremy Taylor and Thomas Fuller, down to the days of that genial but true moralist, the *Spectator*. A few of the more common old English oaths—all in Shakespeare—were 'Bodikins,' 'By Cock and Pie' (*God and the Roman service-book*), 'Cock's passion,' 'By'r Lady,' 'Marry' (the Virgin Mary), 'By my halidom' (*holiness*), 'Od's me,' 'Shlood,' 'Gramercy,' 'By the rood' (the Cross), 'Shrew me.' Sir Thopas in the *Canterbury Tales* uses 'By ale and bread,' the dainty Madame Eglantine's greatest oath is only 'By St Eloy,' 'By Jove' and 'By George' are still heard; 'the dickens' (*devil*) already occurs in the *Merry Wives*; 'the

deuce' is at least of the 17th century, although hardly Middle English, *pace* Professor Skeat; 'By the living Jingo' has been boldly described as *Basque*, and was rendered classic by the *Vicar of Wakefield*; Etheredge and Dryden write 'bloody drunk'; Swift, 'bloody cold' and 'bloody sick'—early examples of one of the most odious of modern vulgarisms; the Duke of Wellington's 'twopenny damn' (of which there is an attempted innocent explanation) almost died with him; Queen Elizabeth, James I., Lord Thurlow, Pictou, and Lord Melbourne, all notorious swearers, were catholic in their choice of oaths. The prophecy of Bob Acres (*Revels*, ii. 1), that 'damns have had their day,' has not yet entirely come true, although the reformation of manners has long since driven swearing from the quarter-deck, and a Squire Western is now more than a phenomenon. Swift's *Swearer's Bank* (Scott's *Swift*, vol. vi.) is a characteristic satire on the profanity of his day. It is computed by geographers, he begins, that there are two millions in this kingdom [Ireland], of which number there may be said to be a million of swearing souls. It is thought that there may be 5000 gentlemen, each with one oath a day at a shilling each, yielding an annual revenue of £91,250. All classes of citizens contribute to this revenue, the farmers, the commonality, the hundred pretty fellows in Dublin alone at fifty oaths a head daily, the oaths of a little Connaught fair themselves computed at 3000. Militia under arms are to be exempted, nor is any advantage to be taken of any man's swearing in the Four Courts, provided he is at hearing in the exchequer or has just paid an attorney's bill. As for its medicinal use to help the lungs to throw off any distilling humour, on certificate of a course of swearing granted by any physician a permit may be issued to the patient, but all other licenses, compositions, or indulgences whatever are prohibited.

The church ever denounced profane swearing, but was powerless to check the practice. St Chrysostom spent twenty homilies upon it, and St Augustine's judgment is summed up with unnecessary severity in the solemn passage, 'Non minus peccant qui blasphemant Christum regnantem in cœlis quam qui crucifixerunt ambulantes in terris.' For much of our popular swearing is little more than the mere habit of vocabulary, a sin only from the lips outward, as Bishop Lightfoot said of the habitual profanity of the colliers of his diocese. Again, where swearing is a professional custom it is scarce possible to exist without conforming, and after all words have in themselves no absolute but a relative meaning. 'Our armies swore terribly in Flanders' in my Uncle Toby's time, as they have done since. And have we not still our familiar proverb 'to swear like a trooper,' 'To swear like a bargee' is a proverb still justifiable by the facts—an atmosphere of oaths continues to hang heavy over our canals and rivers. We are told that Robert Burton at last could only be made to laugh by going down to the Bridgefoot in Oxford and hearing the bargemen scold and storm and swear.

The old forms of excommunication in ecclesiastical use supplied forms enough, and the specimen of the powers of Emulphus given in *Tristram Shandy* certainly displays 'an orientality we cannot rise up to, a copiousness of invention, a possession of all the excellencies of a swearer which make it impossible to swear out of it.' The advantage of a theological vocabulary is seen further in Scott's story of the swearing-bout between a skipper and a broken-down minister, where the latter swore his antagonist dumb with a copiousness and variety he could not equal. In England the growth of Unitarianism was marked by

a series of attempts to stamp out swearing. In 1601 a measure for this end was introduced into the House of Commons, and one was carried in 1623. 'Not a man swears but pays his twelve pence,' says Cromwell proudly of his Ironsides. As early as 1606 swearing in plays had been forbidden, and even Ben Jonson himself narrowly escaped the £10 penalty. An act of 1645 in Scotland details the penalties to be inflicted, even on ministers of religion—it will be remembered that Barham recommends these not to go beyond 'zooks,' Shirley's play, *The Young Admiral* (1633), is especially noted as 'free from oaths, profaneness, and obscenity.' When Davenant's *Wits* next year was presented to Sir Henry Herbert for license, the latter crossed out many expressions. Davenant appealed to the king, who directed the Master of the Revels to allow such words as 'Faith,' 'Death,' and 'Slight.' Sir Henry made the following entry in his office-book: 'The king is pleased to take "Faith," "Death," and "Slight" for asseverations and no oaths, to which I do humbly submit as my master's judgment; but under favour conceive them to be oaths, and enter them here to declare my opinion and submission.' St Paul's Cathedral is supposed to have been built without an oath, the regulations of Sir Christopher Wren being so stringent, and this may be allowed to remain its most remarkable distinction.

Profane swearing, according to the law of England, is an offence for which the party may be convicted under an act of George II. by a justice of the peace according to a scale of penalties. A day labourer, common soldier, sailor, or seaman forfeits 1s. per oath; every other person under the degree of a gentleman, 2s.; and every person above the degree of a gentleman, 5s.; for a second offence, double these sums; for a third, treble, &c. If the cursing take place in presence of a justice of the peace, the latter may convict the swearer then and there, without further process or evidence; and in all cases a constable may apprehend a profane swearer, and carry him before a justice. On one occasion a man swore a volley of oaths, twenty times repeating the oath, and the justices fined him 2s. for each repetition, making in all £2, and this was held a proper conviction. It seems that this act does not apply to women; but there are provisions of a more general character in several modern police acts which impose a penalty for using profane or obscene language in public places. Profanity by cursing and swearing is never prosecuted now in Scotland except as part of disorderly conduct.

See articles on BLASPHEMY and OATH; also Julian Sharran, *A Cursory History of Swearing* (1884).

Sweat (O.E. *sweat*), the moisture exuded by the skin, in which about 2 per cent. of solid matters is present, consisting of salt; formic, acetic, butyric, and other fatty acids; neutral fats; and cholesterin. The manner of its excretion, its uses, &c., are considered at Skin (q.v.).

Sweating Sickness, an extremely fatal epidemic disorder, which ravaged Europe, and especially England, in the 15th and 16th centuries. It derives its name 'because it did most stand in sweating from the beginning until the ending,' and, 'because it first began in England, it was named in other countries the Engliche sweat.' It first appeared in London in September 1485, shortly after the entry of Henry VII. with the army which had won the battle of Bosworth Field on August 22. It was a violent inflammatory fever which, after a short rigor, prostrated the powers as with a blow, and amidst painful oppression at the stomach, headache, and lethargic stupor, suffused the whole body with a fetid perspiration. All

this took place in the course of a few hours, and the crisis was always over within the space of a day and night. The internal heat which the patient suffered was intolerable, yet every refrigerant was certain death. 'Scarce one amongst a hundred that sickened did escape with life' (Holinshed)—a statement which, while probably greatly exaggerated, illustrates the dread with which the malady came to be regarded. Two lord mayors of London and four aldermen died within one week; and the disease for the most part seized as its victims robust and vigorous men. It lasted in London from the 21st of September to the end of October, during which short period 'many thousands' died from it. The physicians could do little or nothing to combat the disease, which at length was swept away from England by a violent tempest on New-year's Day. In the summer of 1508 it reappeared in London, and in July 1517 it again broke out in London in a most virulent form, carrying off some of those who were seized by it within four hours. It seems chiefly to have attacked those in the upper classes or in comfortable circumstances. In many towns a third or even a half of the inhabitants are said to have been swept away, again probably an overstatement. On this occasion the epidemic lasted about four months. In May 1528—the year in which the French army before Naples was destroyed by pestilence, and in which the putrid fever known as *Trousse-gaïent* decimated the youth of France—the sweating sickness again broke out in the metropolis, spread rapidly over the whole kingdom, 'and fourteen months later brought a scene of horror upon all the nations of northern Europe, scarcely equalled in any other epidemic.' How many lives were lost in this epidemic, which has been called by some historians *the great mortality*, is unknown; the fact that King Henry VIII. left London, and endeavoured to avoid the disease by continually travelling, shows the general feeling of alarm that existed. We hear of it at Calais in the same year, but nowhere else out of England. In the following summer, having apparently died out in England, it appeared in Germany, first at Hamburg, where it is recorded that 8000 persons died of it, and shortly after at Lubeck, Stettin, Augsburg, Cologne, Strasburg, Hanover, &c. In September it broke out in the Netherlands, Denmark, Sweden, and Norway, whence it penetrated into Lithuania, Poland, and Livonia; but after three months it had entirely disappeared from all these countries. For three-and-twenty years the sweating sickness totally disappeared, when for the last time (March or April 1551) it burst forth in Shewsbury, spread rapidly over the whole of England, but disappeared by the end of September. The deaths were so numerous that one historian (Stow) states that the disorder caused a *depopulation* of the kingdom. The very remarkable observation was made in this year that the sweating sickness uniformly spared foreigners in England, and on the other hand followed the English into foreign countries. The immoderate use of beer amongst the English was considered by many as the principal reason why the sweating sickness was confined to them. Since 1551 the disease has never appeared as it did then and at earlier periods. Its nearest ally is Sudamina (q.v.), or military eruption, which has appeared in frequent, but usually limited, epidemics in France, Italy, and Germany (still called there 'the English sweat') during the 18th and 19th centuries, sometimes, as in the 'Picardy Sweat' of the 18th century, in so severe and even fatal a form as to suggest the older epidemic in miniature.

See Dr John Caius, *A Booke against the Sweating Sicknesse* (1552); Hecker, *Epidemics of the Middle Ages* (Syd. Soc. Trans.); Hirsch, *Geographical and Historical*

Pathology (New Syd. Soc. Trans., vol. i. p. 82); and Creighton, *History of Epidemics in Britain* (1891).

Sweating System. This subject was first brought prominently before the public in 1847–48 by the *Morning Chronicle* newspaper, and subsequently by a pamphlet (*Cheap Clothes and Nastiness*) and a novel (*Alton Locke*), both from the pen of Charles Kingsley. It was shown that some of the journeyman tailors, instead of doing the work on the premises of their masters, had commenced the practice of taking the garments to their own houses, where they called in the assistance of their families and of other persons. This system was called 'the Sweating (i.e. over-working) System,' because the persons employed under it worked harder than the public opinion of the men in the tailoring trade considered reasonable; just as an unconsciously industrious schoolboy is reproached by his fellows for 'swatting.' The term, 'the sweating system,' soon began to be applied to more or less analogous practices in other trades, and generally to all practices objected to by the workers. 'Sweating' is now used to denote unfair treatment of any kind, without reference to any particular system of employment. But the sweating system is still chiefly applied to cases in which work is sub-contracted—i.e. in which a principal employer, instead of having the work done by men in his own employment, hands it over to a 'middleman,' who gets it done with the assistance of persons engaged by him for the purpose. In some cases the sub-contractor and his employees work on the premises of the principal employer, this type of middleman being usually called a 'piece-master.' But, as a rule, when the sweating system is spoken of reference is made to the 'sweating-master' or 'garret-master,' who employs his workpeople in his own 'sweating-den.' In February 1888 a select committee of the House of Lords was appointed to examine into the sweating system in East London, the reference being afterwards extended to cover the United Kingdom. The industries investigated included the tailoring trade, shirt-making, mantle-making, furriery, boot-making, cabinet-making and upholstery, chain and nail making, the cutlery and hardware trades, and also dock labour and government contracts. The final Report of this committee, published in April 1890, states that 'the earnings of the lowest class of workers are barely sufficient to sustain existence. The hours of labour are such as to make the lives of the workers periods of almost ceaseless toil, hard and often unhealthy. The sanitary conditions under which the work is conducted are not only injurious to the health of the persons employed, but are dangerous to the public, especially in the case of the trades concerned in making clothes, as infectious diseases are spread by the sale of garments made in rooms inhabited by persons suffering from smallpox and other diseases. . . . As a rule, however, it must be remembered that the observations made in respect to sweating apply, in the main, to unskilled or only partially skilled workers, as the thoroughly skilled workers can almost always obtain adequate wages.' While blaming employers as 'regardless of the moral obligations which attach to capital when they take contracts to supply articles and know nothing of the condition of the workers by whom such articles are made, leaving to a sub-contractor the duty of selecting the workers,' the committee declare that 'the middleman is the consequence, not the cause of the evil; the instrument, not the hand which gives motion to the instrument, which does the mischief. Moreover, the middleman is found to be absent in many cases in which the evils complained of abound.'

On the other hand, the middleman or sub-con-

tractor is certainly present in very numerous instances in which the evils of sweating are absent. Thus, in the cotton trade, the 'minders' employ their own 'piecers'; in the iron trade a great number of operations are entrusted to sub-contractors ('puddlers' employing their own 'underhands,' 'hammermen' employing their own assistants, &c.); sub-contract is widely prevalent in mines and quarries, in the ship-building and in numerous other industries, but is in these cases unaccompanied by serious oppression of the workers, and is not called the sweating system. The sub-contractor usually himself performs a part, generally the most difficult part, of the work, and in all cases renders useful services by organising and directing the labour of his subordinates; while the remuneration which he receives is, as a rule, by no means out of proportion to the importance of the duties which he fulfils. But, since the amount of his remuneration depends directly upon his getting his employees to do a *maximum* of work for a *minimum* of pay, the sub-contractor, especially if his workpeople are deficient in skill or incompetent to combine against oppression, tends to become a greedy and exacting task-master.

The laws relating to factories and workshops and to the public health have been amended so as to embody most of the principal legislative provisions recommended by the Lords' Committee. A further check to the development of the sweating system has been given by the 'Fair Wages Clauses,' which it has for some time past been the practice to insert in all government contracts and in those of a considerable number of local authorities: clauses which stipulate for payment of full current rates of wages, and in many cases forbid sub-contract (except with permission). But the most decisive action taken for the remedy of the industrial evils under consideration is the enactment of the Trade Boards Act, 1909. Under this law, which applies to tailoring (other than retail bespoke), to box-making (paper, cardboard, clip, &c.), to machine-made lace and net finishing and mending and darning operations of lace curtain finishing, and to hammered and dolted or tommed chain-making (all trades in which sub-contract more or less extensively prevails), and has been extended to other sweated industries, provision is made for fixing minimum rates of wages enforceable by law. The Trade Boards Act of 1918 extended the scope of that of 1909.

Further details in respect to the sweating system will be found in three Reports by J. Burnett, Labour Correspondent of the Board of Trade: (a) on the Sweating System at the East End of London; (b) on the Sweating System in Leeds; and (c) on the Nail Makers and Small Chain Makers in South Staffordshire and East Worcestershire (1887, 331; 1888, c. 5513; 1888, 385); the five Reports, Minutes of Evidence, Appendices, and Index of the Lords' Committee on the Sweating System; *Booth, Life and Labour in London* (first series, vol. iv.); and *Methods of Industrial Remuneration*, by David Schloss.

Sweden (*Sverige*), a kingdom of northern Europe, occupying the eastern side of the Scandinavian peninsula, with which from 1814 till 1905 Norway (q.v.) was associated. The Skager-Rak and the Kattegat touch its south western shores. In the far north-east it is separated from Finland by the river Torneå and its affluent, the Muonio. Almost the whole of the eastern side is washed by the Gulf of Bothnia and the Baltic Sea; this last also boats against its short southern coast. The longest line, from north to south, measures little short of 1000 miles, the greatest breadth 250; the area is 173,105 sq. m.; the coast-line is about 1550 miles, not including the countless inlets and indentations. Besides the skerry-islands (see below)

Sweden owns Gothland (q.v.), properly Gottland, and Öland (q.v.).

Physical Features.—The country may be generally described as a broad plain sloping south-eastwards from the Kjölen Mountains (see NORWAY) to the Baltic. The only mountainous districts adjoin Norway; the peaks sink in altitude from 7000 feet in the north to 3800 in 61° 30' N. lat. Immediately south of this point a subsidiary chain strikes off to the south-east, and, threading the lake-region of central Sweden, swells out beyond into a tableland with a mean elevation of 850 feet and maximum of 1240 feet. Fully two-thirds of the entire surface lies lower than 800 feet, and one-third lower than 300 feet, above sea-level.

By far the greater portion of Sweden is built up of crystalline gneisses and granite of the Azöic era, and of limestones, sandstones, clay-slates, and other strata of the Lower Silurian epoch. The non-fossiliferous formations, which fill the western, northern, and large portions of the southern parts of the country, lie as a rule close to the surface or are actually exposed. The Silurian strata are spread out in broad thin sheets, regularly disposed, but broken by large islands of granite, gneiss, eruptive trap (diabase), porphyry, greenstone. The Triassic and Cretaceous systems have just touched the southern end of the country. During the Glacial epoch the whole of Sweden was covered with ice. Its melting accounts for extensive deposits of glacial sand, clay, and gravel, as well as for the gigantic boulders and erratic blocks with which several districts are plentifully strewn, and the long narrow ridges of smooth stones, called *åsar*, that cross the country for many miles in a south or south-easterly direction. The eastern or Bothnian coast, like the western coast of Norway, is gradually rising; whilst the coast of Scania, in the extreme south, tends on the whole to subside. The islands of the skerry-ence (*Skargård*) are nearly all small in size, low, bare of vegetation, and polished by the sea.

The climate of Sweden is continental in the north, along the Norwegian frontier, and on the southern plateau; the regions that border on the sea are more maritime. Yet both summer and winter, in all parts alike, are liable to considerable fluctuations from year to year. The difference between the winter and summer temperatures is of course much greater in the continental parts; for instance, in the extreme north as much as 49° F., whereas at Lund in the south it does not, as a rule, exceed 30°. The lakes in the colder (continental) districts of the north are ice-bound for some 220 days in the year; in the south for only about 90 days. The rainfall is greatest on the coast of the Kattegat (30 inches yearly), and decreases from west to east, and from south to north, being only 16 inches yearly in Norland. The south-east corner is, however, exceptionally dry (17 inches).

Sweden is separated popularly and geographically into three great divisions—Norland, Svealand, and Gotland.

Norland in the north is a region of vast and lonely forests and short, rapid mountain-streams. These torrents, none of them 300 miles long, reach the Gulf of Bothnia along narrow parallel valleys running to the south-east; as they drop from level to level they form cascades and waterfalls, some of remarkable grandeur. Many of the valleys are filled for many miles with ribbon-like lakes, some of great size; whilst their slopes, and the ridges that lie between them, are clothed with dense forests of pine, fir, and birch, with wild berry bushes and similar low shrubs growing in between the trees and around the moss-carpeted blocks of granite and porphyry. Besides the Lapps with their reindeer herds, and the Swedish wood-

cutters and miners, the only denizens of these forest tracts are wild animals (reindeer, bears, wolves, lynxes, gluttons, foxes, lemmings, hares), birds of prey (hawks, eagles, falcons, owls), and game birds (ptarmigan, blackcock, heath-cock, hazel grouse, snipe). The innumerable aquatic birds and the gnats of Lapland must not be forgotten. Numerous little seaports, where the lumber, floated down the streams, is cut up, and the iron ore from Gellivara and other mines is smelted, nestle at the mouths of the rivers. This division is very rich in mineral resources, but iron ore is almost the only one that is extracted.

The central division of Svealand, or Sweden proper, is a region of big lakes, and contains most of the mines. Lakes occupy nearly 14,000 sq. m., or 8.2 per cent. of the total area of Sweden; but in Svealand several of the largest, as Vaner, Vatter, Hjalmar, Malär, are grouped together. Lake Malär bears on its bosom a vast number (1300) of islands, many of them beautifully wooded, with royal palaces or noblemen's castles gleaming through the trees. Its shores too are studded with prosperous towns, castles, palaces, and factories. These great sheets of water are connected together by rivers and navigable canals, and by the same means have communication with the Baltic on the one side and with the Kattegat on the other. In spite of the fact that several rivers pour their floods into these lakes, a process of slow desiccation is going on throughout the region. Indeed the waters of Lake Malär are at so low an elevation that at certain seasons there is an inflow from the Baltic. There is a pretty large area of forest in central Sweden, especially around the reed-fringed lakes. The firs of these districts are highly prized for ships' masts. Svealand possesses almost inexhaustible stores of iron and copper, and in less quantities silver, manganese, nickel, zinc, cobalt, and other minerals.

Gotland, the southern division, contains a much higher proportion of cultivated land than either Norrland or Svealand. Wide plains stretch from the lakes to the Kattegat, and these as well as the southern coast provinces are all under agriculture. The rivers are short; the most important is the Gota, which, after forming the picturesque Trollhätta Falls, pours the waters of Lake Vaner into the Kattegat at Gothenburg (properly Göteborg). Iron occurs in certain districts: Monnt Taberg, for instance, the culminating point of the plateau, near the southern end of Lake Vatter, is a solid mass of magnetic iron ore. In Scania coal is mined, and large quantities of turf are dug. Turf moors cover a tenth of the area of the country. In the island of Gotland, with its capital Visby, are to be found many Gantish remains.

Population.—Since the middle of the 18th century the population has increased at a steady, though not very rapid, rate. In 1750 it numbered 1,785,727; in 1800 it was 2,347,303; in 1850, 3,482,541; in 1880, 4,565,668; in 1910, 5,521,943. The figures for 1920 are given in the subjoined table (with the areas). By nationality the people are all Swedes, except some 30,000 Finns, 7000 Lapps, and 22,000 foreigners, and two thirds of the total population are rural. In 1920 there were fifteen towns with a population exceeding 20,000, of which the principal were Stockholm (the capital, 415,201), Göteborg (200,577), Malmö (111,931), Norrköping (57,377), Helsingborg (45,805), Gävle (36,092), Örebro (35,096), and Eskilstuna (30,103). The percentage of illegitimate births increased from about 6 in 1801 to about 14 per cent. in 1924. Less than 5 per cent. of the population receive poor relief. Some 10,000 persons emigrate every year, mostly to the United States.

Religion and Education.—The state religion is that of the Lutheran Church, ruled by twelve bishops, of whom the Bishop of Uppsala ranks as primate. Except about 22,000 persons, all the population belong to the national church; but choice of religion is perfectly free to every man. In the matter of education Sweden occupies an honourable position amongst the countries of Europe. Primary education is compulsory and free. There is an excellent system of elementary and secondary schools, and there is hardly any illiteracy. Besides normal schools, schools of navigation, and technical schools, there are military, naval, artillery, veterinary, mining, agricultural, and other academies. The highest branches are provided for by the state universities of Uppsala (founded 1477) and Lund (1668); also by the Medical School at Stockholm (1810), and the private universities at Stockholm (1877) and Göteborg (1889). The state universities have extensive and valuable libraries.

Occupations and Industries.—Generally speaking, Gotaland is characterised by agriculture, Svealand by mining, and Norrland by forestry. Of the whole surface of the kingdom, more than half is woodland and forest, and about an eighth cultivated land and pasture. More than half of the total population, however, are dependent on agriculture and its associate callings, though in the 19th century the proportion was much higher (in 1870, three-quarters). There are rather less than half a million farms, of which a half are from 5 to 50 acres in area. The principal crops are oats, rye (of which the ordinary bread of the peasantry is made), potatoes, barley, and wheat, beet for sugar, and roots for fodder. Gardening and fruit cultivation are somewhat neglected. There is comparatively little poultry. Some attention is given to the breeding of cattle and sheep, and both are exported. Butter, upon the preparation of which great pains and skill are now expended, is also sent abroad.

Mining has always been very important, and during the last quarter of the 19th century the production of iron-ore multiplied fourfold. At the beginning of the 20th it amounted to 23 million tons per annum, and in 1924 to 61 million, most of which was exported. About half a million tons are produced annually both of pig-iron and ingot-iron,

while zinc, copper, lead, manganese, cobalt, silver, and, to a certain degree, coal are also obtained.

The greater part of the forest land is found in Norrland, mostly pine and spruce. The logs are easily floated down the rivers and lakes to the ports, but much of the timber is kept in the country for use in the ironworks and other establishments. There is also considerable water-power, still partly undeveloped, in the north of Sweden, though in 1926 a cable was completed across the Sound, taking electric current from Sweden to Denmark.

The industries of Sweden have grown very rapidly since the middle of the 19th century. In 1870 about 12 per cent. of the population depended on industry and commerce, in 1900 about 29, and in 1920 about 44 per cent. In factories generally, some 380,000 persons are employed, of whom about a fifth are women. The most important branches are timber industries (planing, paper, and saw mills and furniture, match, and wood-pulp factories), iron-works, foundries, metal and mechanical works (telephones, cream-separators, electric motors); also sugar mills and refineries, cotton and woollen spinning and weaving, distilleries, breweries, tobacco factories, tanneries, flour-mills, glass, porcelain, and chemical works. The old domestic industries—the spinning and weaving of linen and cotton—still survive in some places.

The inhabitants of the skerry-islands and of the coast-lands are mostly fishermen. Herring and sprats are caught off the southern coast; salmon, eels, flounders, mackerel, haddock, and cod are taken off the east coast. The merchant marine consists in over 2500 vessels of about 1,300,000 tons. Every year about 53,000 vessels of 25,000,000 tons enter and clear the ports of Sweden, the chief of which are Göteborg, Stockholm, and Malmö.

Trade and Commerce.—After the Great War the imports averaged £71,000,000 in value per annum, and the exports £66,000,000. At the beginning of this century they averaged £28,000,000 and £21,000,000, and in 1870 amounted to £7,500,000 and £5,000,000 respectively. The chief imports are minerals (mostly coal), raw and manufactured textiles, metal goods (machinery, &c.), corn and flour, while half of the exports are accounted for by wood-pulp and timber, iron and steel also being important. The principal trade is done with the United Kingdom (to the extent of a quarter), United States, Germany, and then with the Baltic countries.

The total length of railways in Sweden amounts to about 9500 miles, of which about 3500 miles (all the principal lines) belong to the state. The system extends right to Luleå (q.v.), and then across Norrbotten to Narvik on the Ofoten Fjord in Norway, this being well within the Arctic circle. There exist a considerable number of canals, the most important being the Göta Canal, connecting Göteborg and Stockholm with Lakes Vaner and Vättern.

Constitution.—The executive power is vested in the hereditary king, who is advised by a Council of State responsible to the parliament (*riksdag*). The king shares the legislative power with the parliament. He possesses the right of initiative and of veto, except in the matter of taxation. The parliamentary constitution was considerably modified in 1907-9, and again in 1918-21, when the franchise was extended to women. There are two houses, which enjoy equal powers, but sit and vote separately. In both, elections are made by proportional representation, the members are paid, and both sexes are eligible for membership. The First Chamber (150) is elected for eight years (one-eighth being elected each year) by the provincial councils and the municipal councils of certain large towns,

and the members are required to be over the age of 35 and to have a money qualification. The Second Chamber (230) is elected for four years, all at one time, by universal suffrage of both sexes over the age of 23, every elector being eligible for membership. A special committee of the Riksdag is appointed to deal with foreign affairs. The twenty-four provinces and the city of Stockholm are each administered by a governor, or prefect, and a provincial council. The communes (parishes and towns) enjoy a liberal measure of self-government through their own local councils. As a whole, Sweden has become increasingly more democratic in the 20th century.

Justice is administered in the towns by the municipal magistrates and in each rural district by a judge appointed by the king acting with twelve (elected) local assessors, whose verdict, if unanimous, overrules the decision of the judge. Press offences alone are tried by jury. There are three high-court districts, besides the Royal Supreme Court of Stockholm.

Defence.—Military service is compulsory for all Swedes between the ages of 20 and 42. Eleven years are passed in the first line and four years in the second line of the active army (*Bevaring*), and eight years in the reserve (*Landstorm*). Altogether, some 600,000 men could be mobilised in event of war, but the regular peace footing is about 35,000. There is a navy, consisting mostly of destroyers and torpedo-boats for coast-defence. In 1926 an independent air force was created.

Finance.—Since 1920 the budget has been balanced at about £48,000,000 per annum. The chief sources of revenue are the customs and excise duties and the income and property taxes, while the chief items of expenditure are defence and education. Most of the national debt has been incurred for railway-building. Only the Riksbank, the national bank, has the right to issue notes. There are about two and a half million depositors in the savings banks (exclusive of Post-office). A return to a gold standard was made in 1924.

Fahlbeck, *Regeringsform i Sverige* (1911); H. Key, *La vie économique de la Suède*, (1913); Lundberg and others, *The Swedish Nation* (1921); and books of travel in French by Bellesort (1911), and in English by Du Chaillu (1881) and Stevens (1925).

History.—The early inhabitants of Sweden were in all probability Lapps or kindred Finnish tribes. The modern Swedes are almost pure Nordics, though other elements can be traced. Their ancestors seem to have crossed over to the southern parts of Sweden during the Stone Age, some time before 1500 B.C. They drove the aborigines before them into the forests of the north and settled in their lands. At the dawn of the historic period Sweden was occupied by two Teutonic races, the Götar (the *Gentas of Beowulf*, often confused with the Goths) in the extreme south (Gothland or Götaland) and the Swedes (Svear) in the lake-region (Svealand). Their manners and customs were the same; they spoke dialects almost identical; and their kings, elected by the freemen of the tribes, recognised as their common supreme head the priest-king of the great temple of Wodan at Sigtuna on Lake Mälaren (but at Uppsala from the tenth year of the Christian era). These priest-kings ruled for more than one thousand years from the Christian era. The first dynasty was that of the Ynglings; the last king of which, Ingjald Ilrede (died 623), perished

amid efforts to reduce the minor kings to the position of vassal princes. The next dynasty, that of the Skjoldungs, was founded by Ivar Vidfadne (died 647), a mighty conqueror. The most memorable of his successors were the famous Viking kings Harald Hildetand (died 735), Ragnar Lodbrok (794), Björn Jersida (804), and Olaf Skatkonung (1026). During this long period the Swedes were in the countries round the Baltic what the Danes and Norsemen were on the shores of the North Sea (see **NORTHMEN**). In the 9th century, however, Scania was conquered by the Danes; and, except for certain short periods, it remained Danish down to the 17th century. Christianity was first preached in Sweden by Ansgar (q.v.) in the 9th century. From the middle of the ensuing century, for fully two hundred years, the Swedes, who clung fanatically to their heathen faith, and the Götar, who, nominally at least, professed Christianity, were generally arrayed in hostile camps. And this in spite of the fact, or rather in great part because of the fact, that an arrangement was come to by which each race should alternately elect the supreme pontiff-king at Uppsala. Nor did the enmity cease after the Swedes became converted to Christianity under St Erik (IX.), whose religious zeal spurred him on to conquer great part of Finland (1155-60), a country that remained an appanage of the Swedish crown for 650 years. For the next century the Goths and Swedes had separate kings; and the clergy turned the ceaseless strife that ensued to their own account. Earl Birger, a man of great ability and conqueror of the rest of Finland, was the real ruler of the country during the reign of Erik XI. (died 1250), the last prince of the Swedish dynasty, as well as during the reign of his own son Waldemar, who was elected the first of the Folkung kings—to succeed Erik. From the accession of Waldemar the animosities of the Swedes and Götar began to subside, and they gradually melted into one nation.

In the meantime, however, a new source of internal discord had grown up: the incessant wars had fostered the growth of a strong and ambitious nobility, who, with their natural allies, the higher ecclesiastics, not only treated the peasantry with great oppression, and even cruelty, but often either warred upon their king or made him little better than a puppet in their hands. King Magnus I. (1279-90), after deposing and imprisoning his incapable brother Waldemar, governed vigorously, and on the whole justly; he promoted the interests of all classes of his subjects and taught them to respect the law. As his son Birger (1290-1319) was only eleven years of age when he was placed on the throne, the reins of government fell into the wise and able hands of Torkel Knutsson, who added considerably to the territory of Finland and at home simplified the laws. But at length the king, instigated thereto by his brothers, committed a judicial murder upon Knutsson, and began to act arbitrarily. The patriotic party rallied round Mats Ketilmundsson, who guided his country to prosperity through the remaining year or two of Birger's reign and down to his own death in the seventeenth year of the reign of Birger's nephew Magnus II. (1319-63). This sovereign suffered himself to be influenced by unworthy favourites, who involved him in profligate wars abroad and led him into odious tyranny at home. In the end his subjects deposed him and conferred the crown upon his nephew Albert of Mecklenburg (1363-97). But Albert was equally unfitted to govern the turbulent nobles of Sweden; he surrounded himself with German courtiers and soldiers, and in order to support them raised revenues by unjust means, till at length the men whose ambitions he slighted offered the crown (1389) to Margaret (q.v.) of

Denmark, wife of Haco of Norway. This caused strife again; but by the union of Calmar (1397) and the accession of Margaret's grandnephew Eric XIII. the crowns of the three Scandinavian kingdoms became united on one royal head.

During the greater part of the 13th and 14th centuries Sweden was torn by almost constant internal conflicts. Her kings were grasping of power, sometimes incapable, generally tyrannical, and often cruel. Her nobles and ecclesiastics were fierce, turbulent, and unrefined; her people ignorant and rude. Agriculture was much neglected; industry there was none; trade was monopolised by the Hanseatic merchants; literature, learning, and culture scarcely existed at all.

The Swedes' acquiescence in the union of Calmar was, however, little more than a matter of form. In their hearts all were hostile to it, and they could only be kept tolerably quiet so long as they were governed by native viceroys. Even then they frequently forced to take up arms against the Danes, and many bloody battles were fought; for the king of Denmark had a strong party amongst the Swedish nobles and higher ecclesiastics, whilst the people (peasantry) and certain of the nobles were enthusiastically national. The chief events of the long contest, which lasted until 1521, may be summarily related. In 1434 the peasants of Dalecarlia, the most patriotic and liberty-loving in the country, rose in revolt under a clever mine-owner, Engelbrechtsson. They were quieted by the appointment of Karl Knudsson, a Swedish noble, as viceroy of Sweden, to govern in co-operation with Engelbrechtsson. On the death of King Erik's successor (Christopher), in 1448, Knudsson was crowned king as Charles VIII. After reigning nine years he was driven out of the country by Christian I. of Denmark, assisted by Archbishop Bengtsson; but he returned in 1467 and reigned till his death in 1470. During the next thirty-three years Sweden was ruled, in an able and enlightened manner, by Knudsson's nephew Sten Sture (q.v.). He was succeeded by his nephew Svante Sture (1503-12), and Svante by his son Sten Sture the Younger (1512-20). This ruler, as patriotic and able as his predecessors, was mortally wounded in battle with Christian II. of Denmark. That savage monarch, on 8th November 1520, for the purpose of striking terror into the hearts of the Swedish people, caused ninety-four persons, mostly of noble rank, to be massacred at Stockholm ('the Blood-bath'), and followed up this atrocity by doing to death throughout the country fully five hundred more of the influential among the national party. These deeds roused the Dalecarlians to action: putting themselves under the leadership of Gustavus (q.v.) Vasa, they drove the hated oppressors out of the country, crowned Gustavus king (1523), and tore (1524) to shreds the union of Calmar. The most momentous event in the reign of this the ablest prince who had yet ruled over the Swedes was the adoption of the Reformed doctrines, principally through the exertions of Olaus and Laurentius Petri (q.v.) and the deliberate policy of Gustavus, who in reforming the church took care that the clergy did not make themselves too powerful.

Gustavus so endeared himself to his subjects that they declared (1544) that the throne, instead of being elective as hitherto, should be hereditary in the House of Vasa. Accordingly on his death the crown was given to his son Eric XIV. (1560). In a reign of eight years this prince did many foolish things, and even some arbitrary and cruel acts; he was at length deposed by his brother John III. John, without openly breaking with the Protestant Church, warmly countenanced the

Jesuits in their attempts to recover Sweden for the Roman see. His son Sigismund, who had been chosen king of Poland in 1587, and assumed the Swedish crown in 1592, pursued the same policy, but in a more undisguised and resolute manner. The Protestant party, however, rallying round Sigismund's uncle, made (1600) him King Charles IX. in his nephew's stead. Charles re-established the Lutheran creed, curtailed the privileges of the nobility, fostered mining, laid out seaports, and made the weight of his influence felt in Russia and Germany. His successor was his illustrious son Gustavus (q.v.) Adolphus (1611-32). After his heroic death at Lützen the crown passed to his daughter Christina (q.v.), though for some time the real ruler was the great Oxenstierna (q.v.). By the acquisition, through the treaty of Westphalia (1648), of the ecclesiastical domains of Bremen and Verden, and the greater part of Pomerania, Sweden became a member of the empire. Further, a war with Denmark brought to the Swedish crown certain of the Baltic islands and the three southern provinces of Sweden (Scania). But in 1654 Christina resigned the crown to her cousin Charles (X.), Palgrave of Zweibrücken. Having crushed his Polish rival of the House of Sigismund in a terrible battle near Warsaw (1656), this king finally expelled the Danes from the Swedish continent. The accession of his youthful son Charles XI. in 1660 was signalled by an agreement with the Polish branch, who not only abandoned their claim to the Swedish crown, but gave up Livonia and Estonia. In the course of an ill-advised war against Denmark and Brandenburg combined the Swedes suffered several military disasters (notably at Fehrbellin in 1675). The king, concluding peace in 1679, set himself energetically to remove the causes of this national humiliation and weakness, and at his death (1697) left his country once more prosperous and powerful. But the ancient foes of Sweden—Denmark, Poland, and Russia—deeming the accession of the youthful Charles XII. (q.v.) a favourable opportunity to recover what they had lost, made common cause against him. As Charles left no heir the nobles conferred the crown upon his sister, Ulrica Eleonore (1718-20), but utilised the opportunity to wrest much of the royal prerogative from her. The new council of state which the nobility chose from their own order made peace with the enemies of Sweden by selling to them the provinces beyond sea, e.g. Bremen and Verden to Hannover, part of Hither Pomerania to Prussia (Further Pomerania was already lost), and Livonia, Estonia, Ingermanland, and Karelia to Russia. Thus Sweden fell from the rank of a first-rate power which she had held for about a century. All through the reign of Ulrica and her consort, Frederick of Hesse (crowned king in 1720), as well as throughout the long reign of the weak-kneed Adolphus Frederick (1751-71), the kingdom was dominated by the nobles, who, however, were divided into two parties, the Caps, advocates of peace and opponents of royal absolutism, and the Hats, the war party, who were infected with French ideas. Gustavus III. (q.v.), shortly after his accession, abolished the council of state and restored the constitution that had been in force before Ulrica's accession. But neither he nor his son Gustavus IV. (q.v.), in spite of all they did for Sweden, can be called a wise and successful king.

The principal figure in the reign of the next sovereign, Charles XIII. (1809-18), was the French general Bernadotte, who was adopted as heir to the Swedish crown in 1810, and the principal event the acquisition of Norway (1814). Bernadotte succeeded as Charles XIV. (q.v.) in 1818, and in a reign of twenty-six years directed his energies to such schemes as the making of roads and canals, the

cultivation of barren tracts of country, the improvement of the finances and of education. Constitutional reform, replacing the old diet of four estates by a parliament elected largely from peasantry and bourgeoisie, was not carried under Oscar I. (1844-59), but midway through the reign of Charles XV. (1859-72). Sweden has enjoyed uninterrupted peace since 1814, although she came within sight of war with Prussia (on behalf of Denmark) in 1848, with Russia at the Crimean war and the Polish rising of 1863, with Prussia and Austria in 1864, and with Norway in 1905. Oscar II. (1872-1907) was personally popular. But the relations between democratic Norway and aristocratic Sweden had never been very cordial; the Norwegians, thinking that the Swedes did not give them perfect equality, had latterly insisted on separate consular representation abroad; and when in 1905 the Norwegian Storting formally claimed this right, the king vetoed it. Thereupon the Storting declared the union dissolved. The Swedes protested, but amicable arrangements were made by both countries to make the separation formal; and by the end of the year the kingdom of Norway had its new (Danish) king (see NORWAY).

The history of the first quarter of the 20th century can be divided into four heads. (1) The growth of industrialism (see *Occupations and Industries*) has been accompanied by the inevitable rise of trade unions and of employers' associations, while the state has associated itself with many important enterprises. After the Great War, Germany entered the lists again as a serious competitor for Swedish trade. (2) As regards the liquor question, drunkenness, formerly the great national weakness, has now enormously decreased, all traffic in drink being now regulated by the state or by the local authorities. Chiefly owing to the efforts of a preacher, Peter Wieselgren, the 'Goteborg system' of selling liquor was first put into practice in 1855 (the principle being that all profits, beyond interest on the capital, go to the state), but it was made general only by 20th century legislation and endeavour chiefly through the scheme of G. Bratt. See LIQUOR LAWS. (3) The Great War forced Sweden into a state of armed neutrality, but, owing to her geographical position, she suffered severely from the blockade of the Allies. Recourse was had to food-raiding, and the cost of living went up. Costs of production and wages increased rapidly, but the inevitable reaction and depression brought about the serious economic crisis of 1920-21. (4) The problem of national defence has occupied much attention. Owing, firstly, to pre-war Russian activities in Finland, and then to the close proximity of belligerents of both sides during 1914-18, the Swedish defence forces had to be maintained on a large scale, with a consequent drain on the treasury, but in 1925 reductions in the personnel of both army and navy were made. The dispute with Finland over the Åland Islands (q.v.) was settled by the League of Nations in 1921 in favour of Finland.

See the standard native histories of Fryxell (1831), Geijer, Malmström (1893-1901), and Hildebrand and Stavenow (1921, *et seq.*); various works by R. N. Bain, including *History of Scandinavia, 1515-1900* (1905); Stefansson, *History of Denmark and Sweden* (1916); Maury, *Problems Scandinavia, 1914-18* (1918); and works in German by Arnheim (1917) and Kjellén (1918), and in French by Coissange (1914).

Literature.—Setting aside what was written in the Old Norse tongue (see ICELAND, DENMARK, RUSSIA), there is very little Swedish literature before the Reformation, except a few provincial law-codes, translations of French romances, some folk-songs, chronicles, religious and devotional

works, and translations of parts of the Bible Olavs and Laurentius Petri (q.v.) brought the Reformation doctrines into Sweden, translated the Bible into good Swedish, and manifested an enlightened regard for their mother-tongue. For several years the principal books were theological and historical, such as the sermons of Matthiä (1592-1670) and Svedberg (1653-1735), which are still read. King Gustavus Adolphus founded the library at Upsala and gave direct encouragement to historical research, as by employing Schroderus (died c. 1650) to translate foreign historical works. Messenius (1579-1637) wrote an ambitious history of Sweden in Latin, and illustrated it by a series of historical plays in Swedish, that stood in high repute for more than a century. Political pamphlets and newspapers began to appear about the time of the Thirty Years' War. Bure or Burens (1568-1652), besides constructing a fantastic scheme of universal knowledge, did sound work in Swedish mythology and language (runes).

But the title of 'Father of Swedish Literature' is usually accorded to Stjernhjelm (1598-1672), who composed didactic and humorous poems in the style of the classic epics. Baron Rosenhane (1619-84), in sonnets (*Venerid*), songs, and lyrics, composed in the manner of the French and Italian Renaissance writers, and 'Barelinus' or Dahlstjerna (1658-1709), in a patriotic epic (*The King's Poet*), and in heroic songs, strove to improve the current standards of literature. The Finlander Frese (1691-1728), who wrote very fair poetry, and Sweden's first satirist, Triewald (died 1743), who attacked the older writers, carry us on to Dalin (1708-63), who used his mother-tongue with an elegance and ease never previously attained. The *Argus* was conducted by him in the style of Addison's *Spectator*, and of his other works may be mentioned the witty allegories *Swedish Freedom* and *Sagabout a Horse*. Hedvig Nordenflycht (1718-63) won great fame by her *Sorrowing Turtle-Dove*, a collection of *in memoriam* lyrics. After Dalin's death the leading poets were Count Crenzt (1729-85), a Finlander, whose pastoral idyll *Atis and Camilla* was long admired, and Count G. F. Gyllenberg (1731-1808), though none of his books take very high rank. In prose the most notable writers were Mork (died 1763), author of a didactic romance in the French style, *Adalrik and Gothilda*; Wallenberg (1746-78), who wrote an original work of travel (*My Son at the Gallies*), and the best tragedy (*Susanna*) in the pseudo-classic style since Dalin; and Count von Hopken (1712-89), composer of elegant *éloges* and rhetorical addresses.

But the strength of Swedish intellect in the 18th century seems to have been chiefly expended in the departments of science, as the following names conclusively attest—the Elder Rudbeck (1630-1702), a man of universal scientific attainments and author of *Atlantid* or *Machheim* (in both Swedish and Latin), a book, learned, bold, imaginative, written to prove the identity of Sweden with the Paradise of Plato; the Younger Rudbeck (1660-1740), a botanist; Celsius (1701-44), whose name is perpetuated in the thermometric scale; the traveller Forskäl (1732-6) ; Rosén or Rosenstein (1706-73), the founder of Swedish medicine; the great Linnæus (1707-78); the chemists Bergmann (1735-84) and Scheele (1742-86); and Ihre (1707-80), who compiled the first Swedish dictionary. The mystic Swedenborg (1688-1772), who, however, wrote in Latin, also belongs to this period.

The golden age of Swedish literature is coincident with the reigns of Gustavus III. and IV. (1771-1809). On its threshold stands Bellman (1740-95), an improvisator of the highest genius. His finest work is *Fredman's Epistles*, songs that for gay

humour and witty observation are unmatched in the language. Gustavus III., besides the direct and substantial encouragement he gave to the best literary talent amongst his subjects, founded the Swedish Academy (1786), and tried his royal hand at the drama. The foremost *litterateur* of his reign was Kellgren (1751-95), who made the *Stockholm Post* the supreme organ of literary taste in Sweden. In its pages a memorable feud was fought out between the writers of the old (Lutheran) school and the champions of revolutionary views borrowed in great part from the French encyclopaedists. With this, however, a purely literary conflict was intertwined, carried on between the partisans of the pseudo-classic standards and the advocates of nature and romanticism. Kellgren, who adhered to the pseudo-classic (French) models, excelled in satiric and lyric poems: his *New Creation* is esteemed one of the finest poems in the language; and in conjunction with the king he composed two lyric dramas, *Gustaf Vasa* and *Christina*. Kellgren's ablest ally was Leopold (1766-1829), a master of polished prose, an excellent critic, and formidable and inspiring satirist, who wrote also in verse—odes, narrative and didactic poems, and weak pseudo-classic dramas. Their principal opponent was Thordil (1759-1808), who urged his contemporaries to cultivate something besides mere form, to emancipate themselves from the trammels of rule and law, and draw inspiration directly from nature. Nevertheless the standards of his rivals, although somewhat modified, continued for many years, chiefly through the Academy, to govern the taste of Swedish writers. Besides the three principal contestants the following participated in the fray: Rosenstein (1752-1824), who wrote on æsthetic and popular philosophy themes; Adlerbeth (1751-1818), author of some successful classic dramas and of greatly admired translations of Virgil, Horace, and Ovid; Count Ehrensvard (1745-1800), whose æsthetic writings are conchid in excellent Swedish prose; Count Oxenstjerna (1750-1818), famous for poetic descriptions of nature and humorous and didactic poems, as well as for a good translation of *Paradise Lost*; the poet Lidner (1759-90); and a couple of humorous writers—Kexél (1748-96) and Hallman (1732-1800). Lindgren (died 1815) wrote comedies in the light and sentimental style of Kotzebue. Hojer (1767-1812) is perhaps the ablest and most original philosophical thinker Sweden has produced.

After Leopold's death the mantle of his literary dictatorship was divided between Anna Lenngren (1754-1817) and the Finlander Franzén (1772-1847). The lady, a typical Swedish nature, celebrated the virtues of domestic life with great truth and much poetic feeling. Franzén's lyrics excel in the best qualities of the poets of Finland—a pious naïveté, depth and refinement of feeling, simplicity and clearness of language, and great beauty of versification. Moreover he wrote very good prose (biographies). He is the main link between the Gustavian Academicians and the romantic schools. Archbishop Wallin (1779-1839), besides other poetry, wrote admirable hymns.

Very early in the 19th century ideas akin to those of the German romantic school were promulgated in Sweden by Hammarsköld (1785-1827), a good critic and historian of literature; Livijn (died 1844), author of some extravagant romances and songs; and Askelöf (1787-1848), editor of the magazine *Polyfron*, which, until it was supplanted by *Fosforus*, was the literary organ of the new school. These innovators encountered a good deal of ridicule from the old school, especially from Wallmark (died 1858); and for a time another literary war was waged. But this time the new way of looking at things proved too strong for the

Academic champions. The romanticists received valuable support from Atterberg (1790-1855), one of the best lyric poets (cf. *Fågeln Blå, Sångertott, &c.*) of Sweden; from Palmblad (1788-1852), who wrote good romances (*Falkensvard* and *Aurora Koningsmark*) and clever polemical and miscellaneous works; Dahlgren (1791-1844), whose satire approaches Leopold's and Kellgren's in wit and polish, and whose humorous poems and novels recall Bellman's happiest effusions; Börjesson (1790-1866), the author of one of the best dramas (*Erik XIV.*) in the Swedish tongue; and Agardh (1785-1859), a distinguished publicist. This movement detroned didactic and pastoral in favour of lyric and epic poetry. There was, however, a richer and more momentous tendency operating contemporaneously with the romantic movement. Atterberg indeed directed attention to the ancient Scandinavian mythology, but it was Geijer (q.v.), no less eminent as a poet than as a historian, who pointed to the many virtues of the Swedes' ancestors as models for imitation and sources of poetic inspiration. Tegnéér (q.v.) showed in his early poems considerable sympathy with the approved Academic standards; but eventually he moved into line with Geijer, and thus stationed himself midway between the pseudo-classic and romantic schools. Around these great leaders of the 'Gothic revival' were grouped a crowd of less gifted writers, the more noteworthy of whom were Ling (1776-1839), who, although he wrote one good drama (*Agne*) and some poems, is best remembered as having convinced his countrymen of the educative importance of gymnastics; Nicander (1799-1839), a lyric poet and author of a promising tragedy; Beskow (1796-1868), a biographer and excellent dramatist (*Thorkel Knutsson*); Afzelius (1785-1871), who composed sentimental tales in melodious verse and along with Geijer edited the first collection of Swedish folk-songs; and Gunnarlin (1789-1877), the writer of a first-rate historical novel (*Thord Bondar*, in 1828). Next came half-a-dozen authors who stood more or less apart, each by himself. Almqvist (1793-1866), a man of brilliant genius and almost universal knowledge, and master of an exquisite style, excelled, despite his ultra-romanticism, in nearly all departments of literature; his best books are novels (*Book of the Rose* and *The Palace*). Stagnelius (1793-1823), another pronounced romanticist, is esteemed one of Sweden's best lyric poets, chiefly on the strength of the mystic *Lilies in Sharon*; an almost equal excellence distinguishes the grand epic *Vadmalur the Great* and the dramas *The Bacchantes* and *The Martyrs*. The satires of Sjöberg or 'Vitalis' (1794-1828) compare not unfavourably with those of Leopold. Satire, too, is the principal note in Bishop Fahlcrantz's (1790-1866) *Noah's Ark*, and in the witty but often coarse improvisations of Wadman (1777-1837) and Detlof von Braunn (1813-60). Cederbergh (1784-1835), although he wrote celebrated romances (*Uno von Trasenbergh, Otter Tralling*), does not belong to the romantic school. Böttiger (1807-78) and B. E. Malmström (1816-65) published poetry of more than average merit. 'Talis Qualis' or Strandberg (1818-77), besides writing the satirical and fiery *Songs in Harness*, made an excellent translation of Byron. Wennerberg's (born 1817) student-songs take the same place in Sweden as Von Scheffel's do in Germany.

But a long way the most illustrious poet of the 19th century was the Finlander Runeberg (q.v.), a man of almost the highest poetic genius, but Rydberg (1828-95) was also much admired for his beautiful lyrics. Amongst the remaining poets of the same idealist period may be mentioned Sturén-Becker or 'Orvar Odd' (1811-69), King

Oscar II. (1829-1907), Count Snoilsky (1841-1904), Af Wirsén (1842-1912), and Bååth (1853-1912). The 19th century more than atoned for the paucity of novelists in its predecessors. Amongst the earliest to write in the modern realist spirit was Sophia von Knorring (1797-1848), who described the domestic life of aristocratic circles. But she is overshadowed by Frederika Bremer (q.v.) and Emilie Flygare-Carlén (1807-92), whose stories of the western skerries (*A Merchant's House in the Skerries, The Rose of Tistelön*) were deservedly very popular. Of the other sex Mellin (1803-76) and Sparre (1790-1871) cultivated the historical novel with more or less success. Wetterbergh or 'Uncle Adam' (1804-89) was a warm favourite for his democratic tales and his simple and humorous *Genre Pictures* of Swedish life. Rydberg the poet won fame also for his semi-historical novels (*The Last Athenian, Roman Days*) and learned work on Scandinavian mythology. Crusenstolpe (1795-1865) and 'Orvar Odd' arc, like Rydberg, held up as models of Swedish prose—the former in novels, the latter in sketches and vignettes of Swedish life and in essays and critical papers. The poet Topelius (1818-98) produced perhaps the most artistic historical novels in modern Swedish literature: his (prose) *Army Surgeon's Stories* ranks with Runeberg's *Ensign Stål's Tales*. The light comedies of Blanche (1811-68) and of Jolin (1818-84), as well as the short stories and sketches of the former, run in the same vein of practical liberalism that distinguishes the novels of 'Uncle Adam' and the verse of 'Talis Qualis' and 'Orvar Odd.' The plays of Frans Hedberg (1826-1908) are somewhat more serious in aim. F. A. Dahlgren (1816-95) translated Shakespeare, Calderon, and Heiberg, and wrote a good popular play (*The Verulanders*) and memoirs of the Stockholm stage. The poet Backström (1841-86) wrote some good lyric dramas.

At the end of the 19th century a whole literature grew up out of the social problems and discussions of the day, especially the questions of literary realism *versus* idealism, and of the relations of the sexes. The novel and the drama were the favourite forms of this literature; and deep earnestness, often bitter and pessimistic in mood, and a keen spirit of contention characterised most of its writers. The foremost in this 'modern' movement was Strindberg (q.v.); his fellow-workers, or more frequently antagonists, were Af Geijerstam (1858-1909); Tor Hedberg (1861); Fm Agrell (1849), a playwright; Victoria Benedictsson or 'Ernst Ahlgren' (1850-88), in the excellent novels *Fru Marianne* and *Money*; Anna Leffler (1849-92), novelist and playwright; and Selma Lagerlöf (q.v.), authoress of *Gosta Berlings Saga* and a writer of great poetic imagination and psychological intuition. In opposition to the sombre Naturalistic school may be set the romantic novelist von Heidenstam (1859) and the poets Oskar Levén (1862-1906) and Fröding (1860-1911), whose works are full of richness of colour. Other names worth mentioning are those of the dramatist Molander (1858-1906), the poet Ossianmillsen (1875), the short-story writer Hallström (1866), the essayist Ellen Key (1849), and the novelists Hansson (1860), Söderberg (1869), and Melsted (1875).

The chief representatives of the more special departments of literature during the 19th and 20th centuries can only be briefly enumerated. Historians: Geijer (q.v.), Fryxell (q.v.), Strinnholm (1786-1826), Carlsson (1811-87), Axelsson, Odhner, and Bååth; the principal historians of literature are quoted in the bibliography subjoined to this article. Literary critics: Olof Hansson and the Finlander Vasenius. The ancient civilisation and antiquities of Sweden: Montelius (born 1843), H.

Hildebrand (1842), B. E. Hildebrand (1806-84), Nilsson (1787-1883), Rydberg, and Nystöm. Church History: Cornelius, Reuterdahl (1795-1870), and Anjon (1803-84). Boström (1797-1866) was an able philosopher. The most popular writers of devotional and religious books have been the poet Franzen, Schartau (1757-1825), Wallin, and Thomander (1798-1865). Philology boasts of Rydqvist (1800-78), Sæve (1812-76), and Reitz (1815-68); law and jurisprudence of Schlyter (1795-1888) and Holmsbergsson (1764-1842); painting of Larsson (1853) and Anders Zorn (1860-1920); sculpture of Karl Milles and Karl Eldh (1873); ethnology of Retzius (1796-1860) and Hazelius (1833-1901); botany of Fries (q.v.); zoology of Nilsson (1787-1883); chemistry of Berzelius (q.v.) and Arrhenius (1859); and geographical exploration of Andrée (1854-97), Nordenfjöld (q.v.), and Sven Hedin (1865). Sweden has taken a very special part in the culture of the world by the Nobel prizes, first presented in 1901 out of the foundation left by the inventor Nobel (q.v.).

There are two large standard histories of Swedish literature, both in Swedish, that of Schück and Warburg (illustrated, 1896), and that of Bök, Castrén, Steffen, and Sylwan (new ed. 1926). See also the standard native works of Ljunggren (1818-19), Fryxell, Malinsson (1866-68), and Nyblom (1873-84); various studies by Vassmus (1887), Schück, Warburg, Hanson, Levertin (1901), and Bök; Schweitzer, *Geschichte der skandinavischen Literatur* (1886-89); Boyeson, *Essays on Nineteenth-Century Scandinavian Literature* (1895); Hofberg's *Biographical Dictionary*, in Swedish (1906); *The Oxford Book of Scandinavian Verse*, ed. Gosse and Craigie (1925).

Swedenborg, EMANUEL, was born in Stockholm, 29th January 1688, and died in London, 29th March 1772. His father was Jesper Svedberg, subsequently Bishop of Skara. Swedenborg's lifetime divides itself into two distinct periods; the first, ending with his fifty-fifth year, was given to business, science, and philosophy; the second, of nearly thirty years, was devoted to theology and spiritual communion. Swedenborg was educated at Uppsala, and subsequently travelled for four years in England, Holland, France, and Germany. On his return to Sweden he was appointed by Charles XII. an assessor in the College of Mines, and rendered some service to that monarch at the siege of Frederikshall as military engineer. The family was ennobled in 1719, and the name changed from Svedberg to Swedenborg. Swedenborg is sometimes styled Count or Baron, but erroneously; he was neither, though he had a seat in the Swedish House of Nobles as the head of his family. His mind at this time was busy with mechanical and economical projects. He published short treatises on algebra, giving the first account in Swedish of the differential and integral calculus; on a mode of finding the longitude at sea by the moon; on decimal money and measures; on the motion and position of the earth and planets; on the depth of the sea, and greater force of the tides in the ancient world; on docks, sluices, and salt-works; and on chemistry as atomic geometry. In 1724 he was offered the professorship of mathematics at Uppsala, which he declined from a dislike of non-practical science. Abandoning desultory studies, he devoted himself for ten years to the duties of his assessorship and to a systematic study of the methods of mining and smelting at home and abroad, and to the construction of a theory of the origin of creation. The result appeared at Leipzig, at the expense of the Duke of Brunswick, in 1734, in three massive folios, beautifully illustrated, entitled *Opera Philosophica et Mineralia*. The second and third volumes describe the best

methods employed in the manufacture of iron, copper, and brass. The first volume, entitled *Principia, or the First Principles of Natural Things, being new Attempts towards a Philosophical Explanation of the Elementary World*, is an elaborate deduction of matter from 'points of pure motion produced immediately from the Infinite.' This was followed in the same year by *Philosophical Argument on the Infinite, and the Final Cause of Creation; and on the Mechanism of the Operation of Soul and Body*, carrying the doctrine of the *Principia* into higher regions, and resolving the soul into points of motion, the soul being treated as one in substance with the sun. Dissatisfied with his conclusions, he determined to track the soul to its inmost recesses in the body. His studies in human anatomy and physiology with this end in view were embodied in his *Economy of the Animal Kingdom* (2 vols. 1741) and his *Animal Kingdom* (3 vols. unfinished, 1744-45).

At this point his course as a natural philosopher was arrested, and he entered on his career as spiritual seer. The particulars of the transition are recorded in his diary for 1743-44, and comprise a variety of curious dreams and strange communications; he now professed to enjoy free access to the spiritual world. He resigned his assessorship in 1747, that he might devote himself to the office to which the Lord had called him. In 1749 he made his first public utterance in his new character in the issue in London of the *Heavenly Arcana* (1749-56, 8 vols. 4to.). His life henceforward was spent chiefly between Stockholm, London, and Amsterdam, in writing and printing a variety of works in exposition of his experience and doctrines. There is little in any of these which is not to be found in outline at least in the *Heavenly Arcana*, and a note of its contents may serve, therefore, as a general description of the whole. With many digressions, the *Heavenly Arcana* is a revelation of the internal or spiritual sense of Genesis and Exodus. The early chapters of Genesis are a fragment of an older Word, preserved at this day in Tartary, and are an allegorical and not a literal history. Adam signifies the Most Ancient Church, and the Flood its dissolution; Noah, the Ancient Church, which falling into idolatry was superseded by the Jewish. The spiritual sense pervades the Scriptures, which are the genuine Word of God, as the soul does the body. The exceptions are Ruth, the Chronicles, Ezra, Nehemiah, Esther, Job, Proverbs, Ecclesiastes, the Song of Solomon, the Acts of the Apostles, and the Epistles. These books have an edifying natural sense like other good productions of human authors, but, inasmuch as they do not possess the internal sense, they are not held to be inspired. The Scriptures are read in heaven in their spiritual sense, but, as that sense treats exclusively of God and man as a spiritual being, it is void of every reference to earthly scenes, persons, and events. By reason of its symbolism of the inward sense, the letter of Scripture is holy in every jot and tittle, and has been preserved in immaculate perfection since the hour of its Divine dictation. The Jewish dispensation having reached its period, God appeared in Jesus Christ; He assumed human nature in its humblest condition in the Virgin, wrought it into conformity with Himself, 'glorified and made it Divine.' The effluence from the Lord's Divine humanity is the Holy Spirit. In a sense the reverse of Socinian, Swedenborg was a Unitarian; he saw God in the Saviour, and regarded Him as the sole object of worship. The church initiated by the Divine Advent came to an end in the 18th century, and Swedenborg witnessed the Last Judgment effected in the year 1757 in the World of

Spirits. Then commenced a new dispensation, signified by the New Jerusalem in the Revelation, of which Swedenborg was the precursor, and his writings contain the doctrine. To the objection, that the doctrine is strange and novel, he replied that mankind were not prepared for its reception before that time, and that the early Christians were too simple to understand it.

One object of his mission was the revival of the lost science of correspondences—the science of sciences in the most ancient times. The law of correspondence is universal; the natural world is the outbirth of the spiritual world, and the spiritual world of the invisible mental world. Unseen evil is manifested in things hurtful and ugly, unseen good in things useful and beautiful. Man is a summary of nature; nature is man in diffusion; all things, therefore, in nature—fire, air, earth, and water—every beast, bird, fish, insect, and reptile—every tree, herb, fruit, and flower—represent and express unseen things in the mind of man. The Scriptures are written according to correspondences, and by aid of the science their mysteries are unlocked. By it, too, the constitution of heaven and hell is revealed. There are three heavens, consisting of three orders of angels: the first distinguished for love, the second for wisdom, and the last for obedience. All angels have lived on earth; none were created such. They are men and women in every respect; they marry and live in societies in cities and countries just as in the world, but in happiness and glory ineffable. All in whom love to God and man is the ruling principle go to heaven at death. Between heaven and hell a perfect equilibrium is maintained. As there are three heavens so there are three hells, and every angelic society has an infernal opposite. Hell, as a whole, is called the Devil and Satan; there is no individual bearing that name. All in whom self-love is the ruling motive go to hell. There is no resurrection of the earthly body. Every one passes to his final lot at death, some making a short sojourn in an intermediate state, designated the World of Spirits, where the good are cured of their superficial infirmities and intellectual errors, and where the evil are stripped of all their pretences to good. Swedenborg's other notable works (all first published in Latin) are *Heaven and Hell*, *The New Jerusalem and its Heavenly Doctrine*, *Angelic Wisdom concerning the Divine Love and the Divine Wisdom*, *Angelic Wisdom concerning the Divine Providence*, *The Apocalypse Revealed*, and *The Delights of Wisdom concerning Conjugal Love*; his whole translated theological works numbering forty volumes of a good size.

Swedenborg professed to enjoy acquaintance with many departed celebrities, and some of his verdicts on character reverse the estimates of history. Nor was his intercourse confined to spirits from earth, but extended to souls from the moon and the planets. For these visions, experienced whilst sitting in his chamber, he had this explanation: although in the spiritual world there are *appearances* of space, there is nothing of the objective reality which here divides London from Melbourne. If one spirit desires to see another, the desire instantly brings them together. A good man is, as to his mind, in heaven, and an evil man in hell; and supposing the spiritual sight of either were opened—i.e. if the eyes of the spiritual body, which transfuse and animate the material ones, were disengaged from their fleshly vesture—he would see his spiritual companions and the country where he would abide after death.

The grand and distinctive principle of Swedenborgian theology, next to the doctrine of the Divine Humanity, is the doctrine of life. God alone lives. Creation is dead—man is dead; and their appar-

ent life is from the Divine presence. God is everywhere the same. It fallaciously appears as if He were different in one man and in another. The difference is in the recipients; by one He is not received in the same degree as another. A man more adequately manifests God than a tree; that is the only distinction. The life of devils is God's presence perverted in disorderly forms. 'All things, and each of them to the very innermost, exist and subsist instantly from God. If the connection of anything with Him were broken for a moment it would instantly vanish; for existence is perpetual subsistence, and preservation is perpetual creation.' By this law of life is explained man's self-consciousness, freedom, and personality— notions communicated from God to man.

Swedenborg made no attempt to establish a sect. When he proclaimed the Christian Church at an end, his expectation was that a new church would be raised up among the Gentiles; but towards the close of his life he spent his energies in attacking orthodox theology, Catholic and Protestant, as if bent on the conversion of Christian lands, but especially of northern Europe. All his works were written in Latin, and received small measure of attention from his contemporaries. Swedenborg was shrewd in worldly affairs, affable in society, and discussed politics and finance in the Swedish Diet like a man of the world, and that for nearly a score of years after he began to write and publish his theological works. He was never married. His diet was chiefly but not wholly vegetarian. In 1908 his body was removed from St George's in the East in London to Stockholm for reinterment.

The Swedenborgians—properly 'The New Church' signified by the New Jerusalem in the Revelation—were first organised as a distinct denomination in 1788 by Robert Hindmarsh (1759-1835), a printer in Clerkenwell, who became one of the first ministers. The church, which accepted Swedenborg's voluminous theological writings as containing a revelation from heaven, gradually increased in numbers. There have always been a number of receivers of the doctrines of Swedenborg among the clergy of the Church of England. The first translator of the *Heavenly Arcana* and many of the other theological writings of Swedenborg was the Rev. John Clowes (1743-1831), rector of St John's, Manchester, for sixty-two years, who both in the pulpit and in his numerous publications made no secret of his faith. From the first, those who accepted Swedenborg's teachings have been divided into separatists and non separatists.

Sweepers are oars of great length used during a calm or in still water, either to assist the rudder or to propel the vessel. See also CHIMNEY.

Sweepstakes, a method of gambling by which several persons contribute each certain stakes, the whole of which fall to one when a certain event happens. In the case of horse-races, each contributor gets either a horse or a blank (by lot or otherwise), and the one whose horse wins takes the stakes, though often the other horses that are 'placed' secure a share for those who have drawn them. Raffles and sweeps are illegal, though constantly carried on without interference from the authorities (see GAMBLING). The Pari-Mutuel is a kind of sweepstakes (see BETTING).

Sweet, HENRY, born in London, 15th September 1845, studied at Heidelberg and Oxford. He published many Old and Middle English texts, readers, and primers, and works on comparative philology

and phonetics, including *An Anglo-Saxon Reader* (1876-87), *Oldest English Texts* (1885), texts of King Alfred, *A History of English Sounds* (1874; new ed. 1888), *Elementarbuch des Gesprochenen Englisch* (1888), *The Student's Dictionary of Anglo-Saxon* (1897); and did much to introduce rigorously scientific conceptions and methods in philology from Germany to England. He died 30th April 1912. His *Collected Papers* were edited by H. C. Wyld (1913).

Sweet Pea. See LATHYRUS.

Sweet Potato (*Ipomoea Batatas*), a twining or climbing plant of the Convolvulaceæ, with stems 5 or 6 feet long trailing on the ground or clambering over neighbouring shrubs. The leaves are 5 or 6 inches long, heart-shaped at the base; the flowers pale purple, closely resembling those of the common convolvulus or bind-weed. It has been long cultivated in the tropical and subtropical countries of both hemispheres, and its native country is a matter of conjecture. It appears to be first mentioned by Pigafetta, an author of the 16th century, who found the root much used by the Indians of Brazil as an

Sweet Potato (*Ipomoea Batatas*).

article of food. It was introduced into Spain about 1519, and the roots were known in England some time before the introduction of the potato, with which they were often confounded by the earlier writers on the latter. English supplies in those times were obtained from Spain and the Canary Islands, and the roots, when steeped in wine or made into sweetmeats, were regarded as restorative of failing vigour. The plant is cultivated in India, China, Japan, the Malayan Archipelago, throughout tropical America, and in the southern United States, in southern Europe, the Canary Islands, Madeira, and North Africa. The roots grow to a great size—to as much as 50 lb. weight, according to some authorities, in Java, but the ordinary average is from 3 to 12 lb. In favourable conditions in the United States the yield per acre is from 200 to 300 bushels. The taste of the roots is sweetish and agreeable, and they are considered to be superior to the common potato in flesh-forming matters. 1. *Jalapa*, a species of Mexico, though purgative, is not the source of the true jalap of the pharmacopœia, as its name suggests, but is so called on account of its being very common in the vicinity of the Mexican town Jalapa. *B. digitata*, which has a very wide geographic

distribution, is commonly cultivated for food in western tropical Africa. The South-west African *I. Scavieri* has tubers of several hundredweights, eaten by the natives, but neither palatable nor digestible for Europeans. It has a cream-coloured milky juice. From the seeds of another species the textile material named Natal Cotton is obtained; it has some resemblance to the true cotton. For *I. Purga*, see JALAP. See also IPOMŒA.

Sweet William. See PINK.

Swetchine, MADAME (*née* Soymanof), was born at Moscow in 1782, joined the Roman Catholic communion under the influence of Joseph de Maistre in November 1815, and settled in France about the end of 1816, dying at Paris in 1857. For about forty years she maintained at Paris a famous salon, characterised by the remarkable peculiarity of a distinctly theological bias. Her husband, General Swetchine, was a quiet, inoffensive man, twenty-five years her senior; she herself was small and plain, with a Calmuck nose and ill-matched eyes; yet she possessed a spiritual beauty and a charm of personality of altogether unusual kind. Her passionate nature had early found safety and perhaps happiness in rigidity of principle and an austere love of heaven; she never had a child; and almost from youth until the end her life was marked with more than the enthusiasm of the convert. Yet she tempered the ardour of zealous and propagandist orthodoxy with all the courtesy of the great world. The church had granted her the rare indulgence of a private chapel in her house, and from the dialectic play of intellect in the salon she passed easily to rapt worship and spiritual communion with God. Her letters and writings, such as those on *Old Age and Resignation*, show subtle thought and elevation of tone, if scarcely distinction of style, but lack the peculiar charm that belonged to her personality, and scarcely justify the enthusiasm of her group of friends whose admiration soon passed into worship.

See M. de Falloux, *Madame Swetchine, sa Vie et ses Œuvres* (2 vols. 1860), and her *Lettres*, by the same editor (2 vols. 1861); also Sainte-Beuve, in *Nouveaux Lundis*, vol. i., and E. Scherer, in *Études sur la Littérature Contemporaine*, vol. i.

Swietenia. See MAHOAGANY.

Swift, a genus (*Cypselus*) and family (*Cypselidae*) of Picarian birds, resembling the swallows in general appearance and habits, but most closely allied by anatomical structure to the humming-birds. They may be distinguished by external characters from swallows thus: 'the swifts have ten primaries, not more than seven secondaries, and only ten tail-feathers, while the swallows have but nine primaries, at least nine secondaries, and twelve tail-feathers.' They have long pointed wings, a short tail, and possess remarkable powers of rapid and prolonged flight. The bill is short, depressed, and weak; the gape wide and fringed by bristles. The legs and toes are short and weak. In distribution the swifts are almost cosmopolitan, but are absent from New Zealand. Two groups are recognised, (a) the Micropodine, or true swifts, with the first toe directed more or less forwards, and a reduced number of phalanges in the third and fourth toes, and (b) the Chaturina, with the first toe directed backwards and the normal number of phalanges in the third and fourth toes. The Common Swift (*Cypselus niger*) is common in almost all parts of the north of Europe and Asia in summer, retiring to tropical or subtropical regions in winter, extending its migrations to the extreme south of Africa. It occurs even in Lapland. Its residence in its summer quarters is much shorter than that of swallows; and it is worthy of

notice that the swift is seldom to be seen along with any of the swallows or martins, the different kinds choosing different localities, even although very close together. The swift is easily recognised in its flight by the remarkably sickle-shaped wings, and its slight scream is very different from the twitter of the swallow. It is bronzed blackish brown, with a white throat; bill, toes, and claws black. It makes its nest in holes in rocks and walls, often in the thatch of houses, crevices in sea-cliffs, quarries, chalk-pits, and trees. The nest is formed of bits of straw, dry blades of grass and bents, feathers, and other such substances, which are apparently glued together by a viscid secretion. The eggs are two in number, and as a rule only one brood is hatched in a season. The swift, like the swallow, seems to return to the same place to nest year after year, and repairs the old nest instead of making a new one. Sometimes it robs martins, sparrows, and even starlings of their nests. Its chief food consists of insects, and the undigested remains are ejected in the form of pellets. The Alpine Swift, or White-bellied

species is known as the *Chimney-swift* in North America, where it is a regular migrant in many parts, wintering in Mexico. Great numbers often build together, sometimes choosing for this purpose an unused chimney in a town. The Swiftlets, genus *Collocalia*, found from India to the Malay Archipelago and in many of the Polynesian islands, one species even in Madagascar, are the builders of edible Nests (q.v.). They breed in deep caves and fix their gelatinous-looking nests, made of mucus unmixd with any vegetable product, to the walls. The nest of one of the true swifts (*Panyptila sancti-hieronymi*) discovered in Guatemala is perhaps still more remarkable, being composed entirely of the seeds of a plant secured together and hung from the under surface of an overhanging rock by the saliva of the bird. 'The whole forms a tube 2 feet 2 inches long by about 6 inches in diameter. The entrance is through the lower end of the tube, and the eggs are placed on a shelf at the top. About the middle of the tube, on the external side, is a protruding cave as if overvaulting an entrance; but there is no hole, and it has the appearance as if it was placed there on purpose to induce some enemy, such as a snake or lizard,' especially during the period of incubation. The Palm Swift of Jamaica (*Micropus phœnicobia*) is also a remarkable nest-builder, attaching its nest of feathers and silk-cotton, felted together, to the surface of a spathe or of a leaf by means of its salivary secretion.

Common Swift (*Cypselus apus*).

Swift (*C. alpinus*), is rarely seen in Britain, but is common in summer on all the high mountain-ranges of southern and central Europe. Eastwards it ranges through Asia Minor and Persia to many parts of India and Ceylon. It is supposed to breed in the extreme south of Africa, where it is common. It builds in high rocks, sometimes in steeples, notably in the cathedral at Bern. It is larger than the common swift, and has a louder note and flies more powerfully. The Needle-tailed Swift (*Acanthylis caudacuta*), an Asiatic species, has been twice found in England, each time in the month of July, but nowhere else in Europe. It is common during summer in south-eastern Siberia, Mongolia, Japan, China, and Tibet; while in winter it migrates as far south as to Eastern Australia and Tasmania. The American Swift (*Chaetura pelagica*) has the hind-toe directed backwards, and the tail-feathers stiff and pointed, as in woodpeckers. It is a small bird, not above 4½ inches in entire length, but one foot in extent of wing. The general colour is brownish black, with greenish reflections, the throat grayish white, the under parts grayish brown. The nest is made of small dry twigs, which the bird breaks off from the tree, and carries away in its feet; and they are attached by means of a viscid secretion to the rock, wall, or hollow tree where the nest is made. From its frequently building in chimneys this

Swift, JONATHAN, Dean of St Patrick's, and the greatest of English prose satirists, came of a Yorkshire clerical family on the side of his father (a lawyer and steward of the King's Inns, Dublin); while his mother, was Abigail Erick, of Leicestershire stock. He was thus related to two English poets, as a Swift to Dryden—for his grandmother was niece to the poet's grandfather, and as an Erick or Herrick to the author of the *Hesperides*. Jonathan Swift was born on 30th November 1667, seven months after his father's early death, at 7 Hoey's Court, which formerly stood near the Castle at Dublin. The only other child was his elder sister Jane. Left with the miserable provision of twenty pounds a year, his mother returned to her family in Leicester, leaving her son's education to the care of his uncle Godwin Swift, who sent him at the age of six to Kilkenny School (then the best in Ireland), where he had Congreve for a schoolfellow, and in 1682 entered him at the age of fourteen at Trinity College, Dublin. His college career was desultory, probably wild, and certainly unsuccessful; and he only obtained his degree *speculi gratia* in 1686. Two years later the turmoil of the Revolution drove him to England, where in 1689 he was received as secretary into the household of the distinguished statesman Sir William Temple (q.v.)—a distant connection of his mother—at Moor Park in Surrey. His proud and independent nature, however, rebelled against the subserviency of the occupation, and after declining a captaincy of horse offered him by William III., who visited Temple's house, and also a clerkship in the Irish Rolls Office tendered by his employer, he left Moor Park for Dublin, where he took orders (deacon, October 1694; priest, January 1695), and was presented by the Lord Deputy to the prebend of Kilroot, near Belfast, of the value of £100 a year. Country obscurity soon proved even less to his taste than waiting upon a great man's literary inspirations, and he was not sorry in 1696 to resign his prebend and accept Temple's invitation to return to Moor Park, and help him with his papers. By this time Esther Johnson (born at Sheen, 13th March 1681, and baptised with the name 'Hester')—immortalised by Swift under the name of 'Stella'—the daughter of a

gentlewoman who acted as companion to Lady Giffard, Temple's widowed sister, had grown into a charming, beautiful, and intelligent girl, and the kindly solicitude of the young Irishman who guided her education was developing into the enduring affection which became the happiness of their two lives. Swift remained at Moor Park till Temple's death in 1699, when he received a legacy of £100 and the privilege of publishing Sir William's posthumous works (which he brought out between 1700 and 1720). His long residence in the house of a cultivated man of the world, despite the subordination that chafed his sensitive pride, had been useful to him. He had found leisure to study; he read enormously in classical and historical literature; he had been brought into personal relations with the king and the ministers, and had learned the business of the politician, which he was soon to practise with signal success. Moreover, the quiet retirement of Temple's house and the solitude of his Irish cure had given him time to produce a masterpiece and a brilliant *tour de force*—the *Tale of a Tub*, and the *Battle of the Books*. The former is held by some critics to be the greatest of Swift's satires; in style and as an artistic whole it certainly stands first. In none of his works is the satire more pointed, the thought more vigorous, the language more nervous and sustained. The cult of religion, the pretensions of letters, the hypocrisies of every form of false virtue or genius are exposed with the keen enjoyment of the iconoclast; the mask is torn from the solemn shams of the world amid derisive laughter. The young genius rejoices in its strength, and spares nothing in its destructive work; and there is something repellent and sacrilegious in its handling of time-honoured beliefs and institutions, though possibly no profanity was intended. The *Battle of the Books*, an admirable travesty of the idle controversy then waging between Temple, Wotton, Boyle, and Bentley, concerning the comparative merits of ancient and modern writers, is a much slighter work, but full of exuberant vitality and humour. Both were published anonymously, like almost all Swift's works, in 1704.

Soon after Temple's death, failing in his application to the court for preferment, Swift became secretary to Lord Berkeley, one of the Lords Deputies to Ireland, and his wit enlivened the society of Dublin Castle by such jests as the *Petition of Mrs Frances Harris* (1700), in verse, and the parody of Boyle, *A Meditation upon a Broomstick* (1704), in prose. After being disappointed of the deanery of Derry, he was given the vicarage of Laracor, near Trim, in West Meath, in 1700, and presented to a prebend in St Patrick's Cathedral; and in 1701 he took his doctor's degree at Trinity College, Dublin. From 1701 to 1710 he divided his time between Laracor and London, where he was employed on ecclesiastical business by the Archbishop of Dublin, and where he contrived to live for half each year on £60. His reputation as a wit, and his suspected authorship of the *Tale of a Tub* and the *Battle of the Books* (to say nothing of his earliest publication, the *Dissensions in Athens and Rome*, a defence of Lord Berkeley, 1701), assured his position in society and in the clubs and coffee-houses, where he constantly spent his evenings with Addison, Rowe, Prior, Congreve, and every one else worth meeting, and found himself ever more and more in request. He now wrote his humorous squibs on the unlucky almanac-maker, Partridge, under the pseudonym of Isaac Bickerstaff, and vindicated his position and opinions as a churchman (sorely damaged by the free speaking of the *Tale of a Tub*) in the *Argument to Prove the Inconvenience of Abolishing Christianity, the Project for the Advancement of Religion, and the*

Sentiments of a Church of England Man (all in 1708). At Laracor he busied himself with improving the vicarage, church, glebe, and garden, of which he was fond. 'I stayed above half the time,' he says, 'in one scurvy acre of ground, and I always left it with regret.' The regret was heightened by the circumstance that Stella, who, by Swift's advice, had come to Ireland with her companion, Rebecca Dingley, passed much of her time between Trim and Dublin.

For the next three years, from September 1710 to June 1713, Swift was chiefly in London, incessantly engaged in political work. The Whigs had done nothing for him, and he detested their war-policy, and their views on the church establishment. The Tories, on the other hand, were full of civility and deference, and longed to win his pungent pen to their cause. Moreover, Swift was personally attracted by the character of Harley, the Lord Treasurer, and a warm friendship soon sprang up between these utterly dissimilar natures. So Swift abandoned his neutral position and became a Tory, and taking over the editorship of the *Examiner*, which had languished in its early days under Bolingbroke and Atterbury, converted it into a deadly weapon of attack against the Whigs. Swift's *Examiners*, thirty-three in number (November 1710 to June 1711), may almost be said to have created the 'leading article' and established the power of the press. They are not remarkable for rhetoric or eloquence, but are simple plain trenchant statements of policy and criticisms of opponents, such as the honest country squire could understand, and would have made himself if he had known how. The backbone of Swift's policy was denunciation of the war party as a ring of Whig stockjobbers, who cared nothing for the country, but out of self-interest played into the hands of the Emperor and the Allies. He urged this view, together with his firm belief in the landed interest and the establishment, in numerous brief and telling skits and broadsides in prose and verse, besides several elaborate argumentative pamphlets, such as the *Advice to the October Club* (1712), *Remarks on the Barrier Treaty* (1712), and the *Public Spirit of the Whigs*, a crushing reply to Steele's *Crisis* (1714); but nowhere so ably and forcibly as in his political masterpiece *The Conduct of the Allies*, published on November 27, 1711, of which the second edition was sold out in five hours on December 1, and a seventh edition reached in the new year. These writings undoubtedly contributed to the overthrow of Marlborough and the conclusion of the peace of Utrecht in 1713. Among slighter satires of this time may be mentioned *The Virtues of Sir Isaac the Magician's Rod* (1710), directed against Godolphin, and the *Windsor Prophecy* (1711). Swift was also engaged preparing his *History of the Last Four Years of Queen Anne*, a laboured production, which was not published till much later; and he also wrote, under his own name, a *Proposal for correcting, &c. the English Tongue* (1712), which includes the oft-suggested notion of a national academy of letters. His life during these three eventful and laborious years is minutely recorded in his wonderful *Journal to Stella*, the most faithful and fascinating diary the world has ever seen, in which all his hopes and fears, his daily work and occupations, his growing influence with ministers, everything in short that he did and all that he thought, are set down in perfect honesty and with no thought of publication, but only for the sympathetic interest of his life-companion Esther Johnson. High affairs of state mingle with playful tenderness and the sweet familiarity of the 'little language,' with a natural charm and frankness which make the *Journal* unique.

Swift's reward for his unwearied labour on behalf of the Tory administration was poor enough. He had throughout kept his independence, and declined to accept the pay of the government like a hired hack. He waited for ecclesiastical preferment; but the queen would not bestow a bishopric on the author of the *Tale of a Tub*. At last in the evil days that preceded the fall of the ministry he was given the Deanery of St Patrick's at Dublin (April 1713), though he would rather have been sent anywhere else. A year later the crisis came; Harley (now Earl of Oxford) resigned, the queen died, the Whigs came into office, and Swift's prospect of political influence in London was gone forever.

A romantic episode in his London life had been the passion he inspired in Esther Vanhomrigh (born not in 1692, but in 1687 or 1688), whom in his usual fashion he called 'Vanessa,' a young girl whom he grew to know intimately at her mother's house in London in 1708-13. He had a fatal habit of playing the mentor to women without looking to the consequences, and there can be no doubt that he behaved with little circumspection in his relations with Vanessa. When he went to Ireland she followed him, and lived sometimes at Dublin and sometimes at a place she had inherited at Celbridge. Whether Swift was married to Stella or not (and there is no satisfactory evidence for the alleged marriage in 1716), the presence of Vanessa in Turnstile Alley, and of Stella in Ormond Quay, on the other side of the Liffey, must have been extremely embarrassing to him; and there is no doubt that he tried to repress Vanessa's passion. She died of a consumption in 1723, and by her testamentary directions Swift's metrical version of their romance was published, with the title *Catalanus* [i.e. *Decanus*] and *Vanessa* (1726). But what his real relations were with the two women, why he did not marry, or, if he did eventually go through the mere ceremony with Stella, as the legend tells, why he kept his marriage a profound secret, and why they never lived together, remain mysteries still, in spite of more than one plausible explanation. The theory that he believed himself tainted with hereditary madness, supported by the fact that he suffered from mysterious attacks in the head due to a disease in the ear, appears to furnish a possible clue to his determination to abjure the privilege of fatherhood; and another reason for his abstinence, compatible with this, has been deduced from the fact that he seems to have never experienced the ordinary emotion of passion. Whatever his passing feeling for Vanessa, there can be no doubt that he was devotedly attached to Stella to her dying day (28th January 1728), and that, in all senses but one, few women have been better loved.

When his hopes of further political work in England were demolished by the accession of King George and the Whigs, Swift, now a man of forty-seven, retired to his deanery, and with the exception of two journeys to England in 1726 and 1727, and occasional visits to friends in Ireland, remained there for nearly thirty years. But political influence and activity were essential to his masterful nature, and accordingly he devoted his energies to the wrongs of Ireland, which were then very real indeed. He did this from no love of the land of his exile, nor out of sympathy with the true Irish: he considered Dublin merely 'a good enough place to die in,' and his voice was raised chiefly on behalf of the narrow Ireland of the Englishry. He defended Ireland only out of 'a perfect hatred of tyranny and oppression' wherever it was found. Nevertheless his ungracious mediation and his unpalatable home-truths bore marvellous fruit throughout the country; he created and guided popular

opinion and for a while made it a power; and the generous impulsive populace worshipped him. His Irish tracts (of which the famous *Draper's Letters*, 1724, directed against a supposed fraudulent introduction of a copper currency known as 'Wood's halfpence'; the *Proposal for the Universal Use of Irish Manufactures*, 1720; and the audacious *Modest Proposal* for utilising children as articles of food, 1729, are among the best examples) possess all the merits of his style and method, his apparent logic, his delightful reductions to absurdity, his burning indignation, his tremendous scorn, and his unsparing virulence in attack. He brought the law upon his printer more than once, but he won the day. 'Wood's halfpence' were suppressed, and the Lord-lieutenant had to confess good humouredly that he governed 'by permission of Dr Swift.'

Besides his Irish tracts, a good deal of light verse—never rising to the level of true poetry, and often exceedingly coarse—and his *Polite Conversation* (1738), a witty parody of small-talk, and *Directions to Servants*, a savage satire on menial incapacity, Swift's Irish period is notable for the completion of the most famous of all his works: *Gulliver's Travels* appeared in 1726, and was immediately on the lips of all the world. This immortal satire needs no description or criticism. In it we see Swift's genius in its full maturity, less impetuous and fiery than in the *Tale of a Tub*, but sterner, more earnest, more majestic in its scorn. It is the terrible earnestness of Swift's indignation at the cant and shams of the world that gives his work its unique force and fire. But with all its deadly satire *Gulliver* is a wonderful story-book, and its daring fancy joined to a strange sobriety and plausibility, its bizarre situations, its inherent possibility, and its delightful playfulness make it a classic favourite with children, as well as men, to whom the scourge is more apparent than the jest. Swift's style is here seen in its perfection; pointed and direct, simple, masculine, absolutely free from affectation, logical and lucid, it always says just what it means, with never a word wasted; its shafts hit the mark fair in the centre with unerring precision.

Of his life during his later years a record is found in his voluminous correspondence with English friends like Pope, Gay, Arbuthnot, Bolingbroke, and his Irish enemy, Dr Sheridan, to name no more. As letters alone they are quite admirable; but as biographical materials they are priceless. No man was stancher in his friendships than Swift, and in spite of his bitter moods he hardly ever lost a friend. They were all he had to live for after Stella's death, except his duties and charities among the poor in the Liberties of St Patrick, where he was adored. His life had become very lonely and sad, and he dwelt in constant dread of that mental overthrow which he felt was coming. In 1740 his brain disease drove him to the verge of madness, but after two years clouded by periods of unspeakable torment he sunk into a helpless, speechless lethargy, and so gradually faded out of life. The long misery and despair, and lonely exile, and final torpor came to an end 19th October 1745, when the most commanding intellect of his time passed from its dreary prison of imbecility to where in the words of his own epitaph, his *seva indignatio cor uterius lacerare negavit*; and the body of the great dean was laid beside Stella, in the same grave, in the cathedral over which he had reigned for thirty years.

The standard edition of the works was Sir Walter Scott's (19 vols. Edin. 1814; 2d ed. 1824), which included most of what was valuable in the earlier collected editions of Hawkesworth and Sheridan. It is now superseded by Temple Scott's edition of the *Prose Works* (12 vols. 1887-1908); W. E. Browning's of the *Poems* (2 vols. 1910);

and F. Elrington Ball's of the *Correspondence* (6 vols. 1910-15). Numerous selections from the works have been made; amongst them are those by S. Lane-Poole, in two volumes, *Prose Writings and Journals and Letters* (Parchment Library, 1884 and 1885), with introductions, criticisms, and notes, which have been used in this article; by W. Lewin (Carnelot Classics, 1886); by H. Morley (Charisbroke Library, 1889-90); and H. Craik (Clarendon Press, 1892). John Forster published the first volume of an exhaustive *Life* in 1875; that by Sir Henry Craik (1881; new ed. 1894) became the standard. See also the short *Life* by Leslie Stephen (1882); the *Life* by Churton Collins (1893); Moriarty, *Dean Swift and his Writings* (1893); and Herbert Paul's *Swift* ('Men of Letters,' 1901). The evidence for the supposed marriage with Stella has been sifted with a lawyer's acumen in *Blackwood's Magazine*, May 1876, by J. Paez, who decides against it. The same conclusion was reached by S. Lane-Poole, *Fortnightly Review*, February 1910. Dr Bernard, Dean of St Patrick's, afterwards Bishop of Ossory, took a view more favourable to the marriage legend in his Introduction to Ball's edition of the *Correspondence*, vol. i. For separate editions of Swift's works, and where preserved, see *Notes for a Bibliography of Swift*, by Lane-Poole (1884); and the much fuller bibliography by W. S. Jackson, in vol. xi. of Temple Scott's edition. Portraits of Swift are to be seen at the Bodleian Library, Oxford, by Jervas, at the Deanery of St Patrick's, at Howth Castle, in Lord Orrery's *Remarks*, and in Nichols's edition of the works.

Swilly, LOUGH, a long narrow inlet of the Atlantic on the north coast of Donegal, Ireland, enters between Dunaff Head on the east and Fanad Point, on which there is a lighthouse (fixed light visible 14 miles), on the west. A second lighthouse, on Dunree Head, has a fixed light visible for 13 miles. The entrance is protected by foris. Lough Swilly penetrates about 25 miles inland, and has a width of 3 to 4 miles. On the eastern shore is the small town of Buncrana, much resorted to for sea-bathing. On its waters a French fleet under Bompart was destroyed in 1798; and in 1811 H.M.S. *Saldanha* foundered at the entrance in a storm, and 300 lives were lost.

Swimming. From time immemorial the great usefulness of swimming has been universally acknowledged, and the ease with which the art of supporting the human body in water can be acquired is a statement as old as the hills. The absolute correctness of the assertion that there is no difficulty in the way of the individual who would become a swimmer is open to question, but it is certain that the number of those who surmount all obstacles grows larger year by year. This is due in no small measure to the greatly increased facilities for the pursuit of this most healthful and pleasurable pastime afforded by the erection of many additional and improved public baths; also to the extensive encouragement the sport receives from the numerous swimming clubs in existence and to the very excellent efforts of the Royal Life Saving Society, and of the Amateur Swimming Association. Valuable aid is given to those wishing to know how to swim by many works on the subject of swimming; but there is no teaching equal to that which is to be obtained in the water with a proficient as guide. The pupil's every movement is watched, mistakes pointed out, and a bad style avoided—a great thing if one wishes to share in the delights of competition, of which there are now so many opportunities.

Opinions vary very considerably as to the best methods to employ in teaching an absolute beginner. In the first place, so much depends on age, temperament, and physical characteristics; some people are endowed with a natural confidence in water, while others must acquire it, often very laboriously. Moreover, there has been such development in swimming strokes in recent years that methods of teaching which used to be regarded almost as

fundamental principles of the art are now considered by many coaches to be obsolete. The same thing applies to the strokes themselves; as new ones have been evolved, the old have been gradually superseded, at any rate for competitive purposes. In this way the breast-stroke, which used to be regarded as the foundation of swimming, has largely gone out of fashion, and is now taught by many coaches only after other strokes have been mastered. Yet the breast-stroke remains one of the most graceful and pleasurable, and withal useful, methods of propulsion through the water, and will always find favour with those who wish to enjoy swimming merely as a healthful pastime and not as a competitive sport. Its great advantages over other strokes are that it enables the swimmer to maintain a natural and comfortable position, to keep the head above water all the time, and to breathe easily; it can be made as strenuous or leisurely as the swimmer wishes, and, though it is not conducive to speed, its value in cases of life-saving has been proved again and again. The first serious rival to the breast-stroke was the under-arm side-stroke, which for a time became very fashionable for racing purposes, but eventually it was superseded by the over-arm side-stroke. When properly executed, this is perhaps the most graceful of all swimming strokes; it is also a general utility stroke of the greatest value, being applicable to long distance swimming or to the attainment of some amount of pace over shorter distances. It is the stroke that has been largely favoured by Channel swimmers from W. T. Burgess onwards. It differs in every respect from the breast-stroke. First, the body is turned sideways in the water, thus lessening the resistance; secondly, the arms are utilised alternately, instead of both together; and thirdly, the legs perform a sort of scissor action instead of the definitely propulsive action used in the breast-stroke. The perfect co-ordination of the movements embodied in the side-stroke requires considerable practice, and many individual swimmers have developed little improvements of their own; but it says much for its effectiveness that it has so far held its own against the more modern variations of the trudgeon and crawl strokes. It was in the seventies of last century that J. Trudgen, returning to this country from South America, introduced the stroke which was named after him, though it is said that a stroke very similar to his was practised by the Assyrians more than two thousand years ago. Though it involved a return to the breast position, and, more or less, the breast-stroke leg-action, the short over arm strokes with each arm without any rolling of the body gave a speed which revolutionised racing methods. After the trudgeon came the crawl, an importation from Australia. This is without a doubt the fastest stroke so far known, and its popularity has spread far and wide. Its success as a racing stroke is due largely to the fact that the body is less submerged than in any other stroke; the action is more that of pulling the body over the water than propelling it under the surface. In its early days it was regarded mainly as a sprint-stroke, unsuitable for longer distances; but in its modern development it has become almost as fashionable with long-distance swimmers as with competitors in short-distance races. Even our Channel swimmers make use of it. The necessity for all swimmers to be able to float and swim on the back is too obvious to need stressing. Some people float better than others, but every one should be able easily to acquire the back-stroke, which is a particularly invaluable aid in life-saving.

It is only natural that with the modern development of speed-strokes has come almost a plethora of record-making. The period since the war has seen

new amateur records established for almost every recognised distance, both by men and women swimmers, and no one can say that finality has been reached. Among such record-makers the names of J. Weismüller (U.S.A.) and Arne Borg (Sweden) stand out with particular prominence. These two swimmers have between them held most of the free style world's records in recent years, and the list passed (Dec. 1926) by the Fédération Internationale de Natation Amateur is as follows: J. Weismüller—100 yards (52 sec., at Seattle, 1925; 100 metres (57½ sec.) in Florida, 1924; 150 yards (1 min. 26½ sec.) in Illinois, 1925; 200 metres (2 min. 15½ sec.) and 220 yards (2 min. 15½ sec.), both at Honolulu in 1922. Arne Borg—300 yards (3 min. 16½ sec.), 300 metres (3 min. 33½ sec.), 400 metres (4 min. 50½ sec.), 440 yards (4 min. 52½ sec.), 500 yards (5 min. 38½ sec.), 500 metres (6 min. 8½ sec.), all at Stockholm in 1925; 880 yards (10 min. 37½ sec.) at Harnas, 1925; 1000 yards (12 min. 16½ sec.) at Gothenburg, 1924; 1000 metres (13 min. 4½ sec.) at Oslo, 1925; 1500 metres (20 min. 4½ sec.) at Budapest, 1926; one mile (21 min. 41½ sec.) at Gothenburg, 1925.

The world's amateur records for ladies are at present shared by six swimmers as follows: Miss M. Vehselan (U.S.A.)—100 yards (1 min. 3 sec.) in Hawaii, 1923; 100 metres (1 min. 12½ sec.) in Paris, 1924. Miss G. Ederle (U.S.A.)—150 yards (1 min. 45 sec.) at Bermuda, 1922; 200 metres (2 min. 45½ sec.) at Brooklyn, N.Y., 1923; 300 yards (3 min. 58½ sec.) at Brighton Beach, N.Y., 1922; and 400 metres (5 min. 53½ sec.), 440 yards (5 min. 54½ sec.), 500 yards (6 min. 45½ sec.) and 500 metres (7 min. 22½ sec.) all at Indianapolis in 1922. Miss E. Mayne (Great Britain)—1000 yards (14 min. 47 sec.), 1000 metres (15 min. 49½ sec.), 1500 metres (24 min. 1 sec.) and one mile (25 min. 46 sec.), all at Exmouth in 1926. Miss H. M. James (Great Britain)—220 yards (2 min. 46½ sec.) at Seacombe in 1923. Miss H. Wainwright (U.S.A.)—300 metres (4 min. 19½ sec.) in Florida in 1924. Miss E. McGarry (U.S.A.)—880 yards (12 min. 56 sec.) at Indianapolis in 1925.

British amateur records are as follows: 100 yards (54½ sec.) by D. P. Kahuananoku (Honolulu) at Exeter, 1920; 150 yards (1 min. 32½ sec.) by C. M. Daniels (U.S.A.) at Manchester, 1908; 220 yards (2 min. 24½ sec.) and 300 yards (3 min. 24½ sec.) by Norman Ross (U.S.A.) at Exeter, 1920; 440 yards (5 min. 18 sec.) and 500 yards (6 min. 1 sec.), by Arne Borg (Sweden) at Weston-super-Mare, 1921; 880 yards (11 min. 25½ sec.) by H. Taylor (Great Britain) at Runcorn, 1906; 1000 yards (13 min. 33½ sec.) by H. E. Amison (Great Britain) at Hastings, 1924; one mile (24 min. 1½ sec.) by T. S. Battersby (Great Britain) at Southampton, 1909; 150 yards back stroke (1 min. 48½ sec.) by A. Rawlinson (Great Britain) at Southampton, 1924; 200 yards breast-stroke (2 min. 41 sec.) by P. Courtman at Garston, 1914. Ladies—100 yards (1 min. 4½ sec.) by Miss C. M. Jeans (Great Britain) at Nottingham, 1925; 150 yards (1 min. 40½ sec.) by Miss H. M. James (U.S.A.) at Southampton, 1923; 220 yards (2 min. 46½ sec.), 300 yards (3 min. 58½ sec.), 440 yards (6 min. 1½ sec.), 500 yards (6 min. 57½ sec.) by Miss James at Seacombe, 1923; 880 yards (13 min. 1½ sec.), 1000 yards (14 min. 47 sec.) and one mile (25 min. 46 sec.) by Miss E. M. Mayne (Great Britain) at Exmouth, 1926; 150 yards back stroke (2 min. 4 sec.) by Miss E. King at Croydon, 1925; 200 yards breast stroke (3 min. 2½ sec.) by Miss L. Gilbert at Garston, 1922. The plunging record for men was held for twenty years by Major W. Taylor, of Bootle, Liverpool, with 82 feet 7 in., but was beaten in September 1926 by F. W. Parrington of Liverpool, who accomplished 85 feet 6 in. The

ladies' record is 71 feet, by Miss Hilda Dand, of Westminster, in 1925.

Perhaps the most remarkable developments in long-distance swimming in recent years have been seen in the many attempts to swim the English Channel, as the following record of successes shows:

	Hrs.	Min.
1875 (Aug. 25), Captain Webb.....	21	45
1911 (Sept. 6), T. W. Burgess.....	22	35
1922 (Aug. 6), H. Sullivan.....	27	25
1923 (Aug. 12), S. Tiraboschi.....	16	35
1923 (Sept. 9), C. Tolt.....	16	54
1926 (Aug. 6), Miss G. Ederle.....	14	30
1926 (Aug. 28), Miss Corson.....	15	28
1926 (Aug. 30), H. Wierkotter.....	12	40
1926 (Sept. 10), G. Michel.....	11	6
1926 (Sept. 17), N. L. Derham.....	18	56

The authenticity of these records has been generally accepted, though in most cases the swimmers have been accomplished without the presence of properly appointed officials. It may be noted that Captain Webb, Burgess, and Sullivan all swam from the English shore; the others all swam from France. It would seem that the difficulties presented by the currents from the French side have now been fairly mastered. It has been shown that speed as well as endurance is an important factor in Channel-swimming, going far to help the swimmer to beat the tides of the tide, which have baffled so many aspirants.

See Wilson's *Swimming Instructor* (1883), Cobbett's *Swimming* (1889), Frank Sachs's *The Complete Swimmer* revised edition, 1923, the *Badminton Book* by Sinclair and Henry (1893; 3d ed. 1900), and that by Ralph Thomas (1904); also CRAMP, RESPIRATION (ARTIFICIAL), DROWNING, and HUMAN SOCIETY.

Swinburne, ALGERNON CHARLES, was born in London on 5th April 1837, but belonged to an old Northumbrian family, being the son of Admiral Swinburne and of Lady Jane Henrietta, the daughter of the Earl of Ashburnham. He was educated at Eton and at Balliol College, Oxford, which he entered in 1857, and which he left without taking a degree. Though in the domain of literature, he read omnivorously. He became closely associated with Burne Jones, D. G. Rossetti, Wm. Morris, Meredith, and Whistler, and spent some time in travelling on the Continent, in 1864 visiting Walter Savage Landor at Florence. His first book, two plays, entitled *The Queen Mother and Rosamund*, was published in 1860, but did not excite much attention. It was otherwise with *Atalanta in Calydon*, which appeared in 1865, and proved that a new singer with an exquisitely lyrical gift had arisen. Swinburne produced no poem of similar length so full of beauties as *Atalanta*; and here are some, and these, perhaps, not the least competent judges of his verse, by whom this drama is even now more dearly prized than any other of his author's works. The tragedy of *Chastelard* was deservedly far less successful, but in 1866 the first series of *Poems and Ballads* made him the most talked-of man in England. The finest pieces, *Tesperia*, *Itylus*, *A Match*, *The Garden of Proserpine*, the *Hymn to Proserpine*, *The Triumph of Time*—these, to name but these, were a revelation to students of English verse. The writer struck a note which none had struck before. One might object to the erotic tone of certain passages, but here is no resisting the lyric fire and the consummate artistry, the magnificence of the rhythm, the new, strange sweetness of the music. About his time his illness, a kind of epilepsy, began to manifest itself in rather an alarming manner. *A Song of Italy* appeared in 1867 and an *Ode on the Proclamation of the French Republic* in 1871. By the publication in the latter year of *Songs before Sunrise* the author was again exposed to censure, extravagant in part and in part not unwarranted. There is much admirable verse—fiery and ringing

and technically perfect—in the volume; but to most readers the revolutionary political opinions underlying it, derived largely from Mazzini and Victor Hugo, appear to be visionary and crude, and to be often intemperately urged. In 1871 Robert Buchanan attacked Dante Rossetti and Swinburne on the score of the alleged immoral tendency of their verse; the acerbic's pamphlet, *The Fleshly School*, drawing forth a counter-pamphlet, *Under the Microscope*, from Swinburne. *Bothwell*, a long chronicle play, without any attempt at theatric structure, in which historic truth, so far as understood by the poet, was made the primary quest, appeared in 1874; *Erechtheus*, a noble lyric drama, extremely unlike *Atalanta*, inasmuch as it was written with great exactitude (even as to the number of its verses) upon the lines of a Greek drama, in 1875; and a second series of *Poems and Ballads* in 1878. In 1879 occurred a decisive event in Swinburne's life, the removal to 'The Pines,' Putney, the home of the critic Watts Dutton (q.v.), who had become acquainted with the poet some years previously. Though this stifled his genius—for practically all Swinburne's best poetry dates from the earlier part of his life—yet at the time it was probably the only thing that could have saved him from a complete breakdown, as during the fifteen years of his life in London his health, aggravated by excesses, had been growing steadily worse, and deafness made intercourse with society dillicult. The record of the next thirty years is one of peaceful life in Suburbia, during which volume after volume was sent to the press with almost monotonous regularity. His later collections of poems include *Studies in Song*; *Songs of the Springtides*; *Heptalogia*, essays in parody; *A Century of Roundels*; a third series of *Poems and Ballads* (1887), containing the superb 'Armada'; *Astrophel*; *The Tale of Balen*; and *A Chunnel Passage*. Among his later plays may be mentioned *Mary Stuart*, which completes the trilogy begun in *Chastelard* and continued in *Bothwell*; *Marino Faliero*; *The Sisters*, a short tragedy of modern life; and *Tristram of Lyonesse*, a fine narrative poem in decasyllabic complets. As a prose-writer, Swinburne published several volumes of critical essays, separate studies on Charlotte Brontë, Blake, Chapman, Dickens, Shakespeare, and Victor Hugo, and a novel, *Lone's Cross Currents*, written in 1887 and published in 1905. He died at Putney, 10th April 1909.

Swinburne was the greatest metrical inventor in English literature. Other poets have equalled him in melody, but none other has revealed the tunefulness and pliancy, the majesty and grace of the English speech in such a variety of lyrical forms. He can impart dignity and distinction to the simplest measures, and move with faultless ease in the most elaborate. He can give rapid and graceful movement to heavy-laden, long-drawn metres which other artists in verse would find unworlably cumbersome. He can stir the blood by the rush and resonance of a battle-chorus, or charm the ear by the music of a love-lyric as sweet as the songs of spring. His music is like no other man's, and whether the verses are running lightly, marching proudly, or swinging impetuously, the music is like irresistible. The charges of tautology and obscurity which, of course, he brought against his tendency to use redundant phrases and unfamiliar inversions, and to carry iteration to excess, especially in the later works, were often the reader is lost in the maze of rhythms being with nature his endeavour was not to produce a perfect minute transcript, but to render the spirit of a scene, to catch and convey the elusive haunting *scymodoce* loveliness or its terror. *The Garden of*

admirably illustrates his descriptive method. You feel at first as if the meaning of certain phrases were escaping you; but as you read, the charm, at once daunting and seductive, of the wonderful sea-hall—the magic of the lovely crimson glimmer and of the gloom which seems to dilate above the black silent water—is borne in upon you by the suggestion of the music, the subtle verbal colouring and shading, the premeditated vagueness of certain lines, as it could never have been by any number of direct and minute descriptive touches. The poem is as perfect in one way as Kents's *Hymn to Pan* is in another. Of all our poets Swinburne was the poet of the sea. He knew the ocean in all its moods, and rendered with equal perfection the revel of storming surges, the magnificent rolling of deep sea billows, the soft glow of the bows of the water-world, the sensuous delight of a swimmer swimming out as the morning breaks over the green rippling deep. The difference between Swinburne's earlier and his later work is only too apparent; the outburst of soaring song and lyric fire in *Atalanta*, and the splendour of rhythm, the witchery of phrase, the passionate imaginative glow of the first two series of *Poems and Ballads* were never surpassed nor even equalled. The plays, especially the monstrous trilogy of *Mary, Queen of Scots*, etc., on the whole, inferior to his lyrics, though they contain some noble passages of poetry. As a critic Swinburne had one pre-eminent excellence, the faculty of discerning and giving the most generous recognition to literary merit in its most dissimilar forms—in Congreve as in Wordsworth, in Pope as in Webster, in Anthony Trollope as in Cyril Tournier. His knowledge of Elizabethan and of French literature was unrivalled, but his idolatry of Victor Hugo not only found expression in immoderate eulogy, but prompted him now and then to belittle the works of other poets. The merits and defects of his prose style are as striking as those of his poetry. The splendid glow and ornate grace of the diction, and the magnificent command of epithet, tended to degenerate into super-emphasis and the employment of figures only admissible in verse. Much of Swinburne's best critical work, however, dates from Putney, where the man of letters found fuller scope than the poet. In personal appearance, Swinburne was small and slightly built, but with a large head emphasised by a mass of reddish hair. His constitution was strong above the average, though a peculiarly nervous temperament made him quickly responsive to the emotions or inspirations of the moment. A probable explanation of his curiously unbalanced life may be found, if he be regarded as a case of 'arrested development.' He never advanced intellectually or poetically beyond the ideas and influences of the early twenties. In absolute maturity and in complete command over the technique of verse, he wrote his masterpiece, *Atalanta*, at the age of twenty-six. Further, while he sublimated liberty almost into a religion, paradoxically no one was held more captive than he in the thralls of hero-worship. The fact remains, however, that Swinburne, almost more than anyone else, enriched English poetry with an infinite variety of sounds and rhythms to warrant Tennyson's just dictum, that 'he is a reed through which all things blow into music.'

A complete edition of Swinburne's poems, including some posthumous work, was published, 6 vols. in 1917. His *Complete Works* in 20 vols. (ed. Gosse and Wise) began to appear in 1926. See *Life* by Gosse (1917); studies by Mackail (1909), Thomas (1912), Paul de Reul (1922), Welby (1926), and Nicholson (1926); Mrs Leith (his cousin), *The Boyhood of Swinburne* (1917); *Recollections* by Kernahan (1917-19); *Letters*, ed. Gosse and Wise (1918); and a bibliography by Wise (1926).

Swindon, a municipal borough of Wiltshire, 77 miles W. of London and 29 ENE. of Bath, consists of Old Swindon (*Scundane* in Domesday), on an eminence $1\frac{1}{2}$ mile S., and New Swindon, which originated in the transference hither in 1841 from Wootton Bassett of the engineering works of the Great Western Railway. The former is rather a picturesque place, with a good Decorated parish church (rebuilt by Sir G. G. Scott in 1851), a town-hall (1852), assembly rooms (1850), and a corn exchange (1867). New Swindon has a mechanics' institute (1843), theatres, hospitals, &c. Pop. (1861) 6856; (1881) 22,374; (1921) 54,920.

Swine. See PIG.

Swinemünde, a fortified seaport of Prussia, on Usedom Island, at the entrance of the narrow channel of the Swine, connecting the Grosses Haff (into which the Oder flows) with the Baltic. It forms the outer port of Stettin, is entered by large numbers of vessels, and has valuable fisheries and excellent sea-bathing. Pop. 16,000.

Swing, a cognomen assumed by senders of threatening letters during the period when the irritation of the agricultural labourers of England against their employers was at its height, namely from 1830 to 1833. This arose from a widespread belief on the part of the labourers that the use of machinery would greatly lessen the demand for labour, and consequently produce a general reduction of wages; it was also intensified by the savage severity with which the game-laws were enforced, and by other hardships to which the labouring classes were subjected. As disregard by landlords or farmers of the demands contained in these threatening letters was constantly followed by the burning of stacks and farm-buildings, the employers of labour became so terrified that in very many cases almost implicit obedience was paid to the dictates of 'Captain Swing.'

Swinton, (1) a town in the West Riding of Yorkshire, 5 miles NNE. of Rotherham. It has manufactures of bottles, iron, pottery, &c. Pop. 14,000.—(2) A town of Lancashire, $4\frac{1}{2}$ miles WNW. of Manchester, with cotton-mills and brick-fields. Pop. of Swinton and Pendlebury urban district (1871) 14,052; (1921) 30,924.

Swiss Guards, a celebrated corps or regiment of Swiss mercenaries in the French army of the old régime, constituted 'Gardes' by royal decree in 1616. Mercenaries as they were, they were ever unwavering in their fidelity to the Bourbon kings, and their courage never blazed more brightly than on the steps of the Tuileries, 10th August 1792. They had been ordered to leave Paris by a decree of the Assembly on July 17th, but had not yet been sent farther than their barracks, when on August 8th, in anticipation of insurrection, they were ordered to march to the Tuileries. Michelet gives their number as 1330; Challamel, Pollio, and Marcel in *Le Bataillon du Dix Août* (1881) as 1200; Louis Blanc as 950; Mortimer-Ternaux as 900 to 950. But the number may now be taken definitely as nearly 800, including the ordinary guard of the king (see Captain de Durler's *MS. Relation* printed by Mr H. Morse Stephens in *Eng. Hist. Review* for April 1887). In anticipation of a storm Mandat had made admirable arrangements to defend the palace, but the National Guards furnished with the insurgents, and Mandat himself was murdered on the steps of the Hôtel de Ville, whither he had gone by the king's command on a summons from the municipality. Meanwhile a growing mob under Santerre, with the famous 500 men of Marseilles at their head, marched on the Tuileries. But before they reached the palace Roederer had persuaded the king to leave the

Tuileries and place himself and the royal family under the protection of the National Assembly. He was accompanied thither by 150 Swiss, besides two hundred gentlemen and about a hundred National Guards. The remainder were left without orders, uncertain what to do, and when Westermann with his Marseillais and a raging mob made their way through the gate of the Tuileries and across the court the 650 Swiss under Captain Durler faced them on the great staircase, knowing only the orders of the night before that they were not to suffer themselves to be forced. Westermann, an Alsatian, tried to win them over by speaking to them in German, but it was not so that these men had learned duty. Some one fired a shot, and the struggle began. The Swiss had already driven back Westermann with about a hundred dead, when the king hearing the firing sent them orders to leave the palace. They fought their retreat across the gardens, while the mob swarmed into the palace and murdered a few wounded men they found there. Those under Durler made their way to the Assembly, were disarmed and placed in the neighbouring church of the Feuillants; but those who were posted in the corridors and rooms of the palace did not hear the order to retreat, and were speedily attacked, overpowered by the mob, and hunted to death. A few fought their way out across the gardens only to find the drawbridge up, whereupon they made for the Place Louis XV., turned a square under the statue of the king, and were cut to pieces where they stood. Few but those who found refuge in the church of the Feuillants survived that fatal day. Fifty-four were sent to the Abbaye and were among the first to perish in the atrocious September massacres. The heroism of the Swiss Guards was fittingly commemorated in 1821 by the great lion outside one of the gates of Lucerne, cut out of the rock after a model by Thorwaldsen.

See Pflyffer d'Altshofen's *Recit de la Conduite des Gardes Suisses* (Lucerne, 1824); Durler's *Relation* already quoted; vol. ii. (1891) of H. Morse Stephens' *History of the French Revolution*; also the article *MERCENARIES*.

Switchback, a term applied to a zigzagging, alternate back and forward mode of progression up a slope. A 'switchback railway' originally meant one where the ascent is up a steep incline simplified by curving the track backwards and forwards (and upwards) on the face of the slope. Afterwards the term came to be applied to a railway where (as at Manch Chunk, q.v.) the movement of the carriages is largely effected by their own weight alone, the descents by gravity and the ascents by a stationary engine. (This railway, once used for carrying coal, was superseded in this capacity by a tunnel, and subsequently reserved for pleasure excursions.) Hence the application to the well-known apparatus for amusing the public at watering-places, fairs, and exhibitions: a short length of elevated railway with a series of rounded inclines, so that the car gains enough of momentum descending the first steep incline to ascend one or more smaller inclines till it gradually and more slowly works its way to the original level at the far end of the course. Thence it returns in the same way. Sometimes these switchbacks are made circular. Very similar were the so-called *Montagnes Russes*, elevated wooden frames with (wheeled) cars rushing down and up the slopes again, designed to represent Russian snow-sleds, which were introduced into Paris as a popular amusement about 1815. The 'Flying Mountains' of St Petersburg had been described by Lord Baltimore in his *Gaudia Poetica* (1770). Thomas Moore's *Epicurean*, published in 1827, and based on some knowledge of the *Montagnes Russes*, describes very nearly the modern switchback.

Swithin, or SWITHUN, St. Bishop of Winchester from 852 to 862. The 11th century Life attributed to Götzelin may contain elements of historical truth, and according to it he was tutor to Egbert's son Ethelwulf, under whom he was made bishop. He was a devoted builder of churches, and a man of unusual piety and humility. He built a bridge at the east side of the city, and here he used to sit and watch his workmen. One day some of them broke an old woman's basket of eggs, whereupon the bishop miraculously restored them. He died in 862 and was buried in the churchyard of Winchester, having asked, says William of Malmesbury, to be laid where 'passers by might tread on his grave, and where the rain from the eaves might fall on it.' A century later he was canonised, and the monks exhumed his body to deposit it in the cathedral; but this translation, which was to have taken place on the 15th July, is said, though unfortunately not by contemporary chroniclers, to have been delayed in consequence of violent rains. Hence the still current belief that if rain fall on the 15th July it will continue to rain for forty days. Unhappily Professor Earle has exploded the ingenious legend about the saint's displeasure, and shown that a much more probable origin is to be found in some primeval pagan belief regarding the meteorologically prophetic character of some day about the same period of the year as St Swithin's. In France the watery saints' days are those of St Médard (8th June), and St Gervais and St Protais (19th June). The rainy saint in Flanders is St Godelieve (6th July), and in Germany among the saints' days to which this belief attaches is that of the Seven Sleepers (27th June).

Switzerland is a confederation of twenty-two cantons, forming a historic republic without a homogeneous nationality or natural geographical frontiers on any side, lying practically in the very centre of Europe, between France, Germany, Austria, and Italy. The greatest length from east to west is 216 miles, the width from north to south being 137 miles; area, 15,940 sq. m. The population in 1850 was 2,392,740; in 1895, 2,986,848; in 1920, 3,880,320.

Zürich (Fr. Zurich), G., P.,		1351	607
Total..		15,940	3,880,320

In the above table the name used by the majority is put first, followed by the French name in the German cantons, and by the German in the French ones. F. or G. or F.G. indicates that the majority

speak French, or German, or both. When neither F. nor R.C. is appended, it is to be understood that the canton is partly Protestant and partly Catholic.

There were thirteen towns in 1920 with population over 20,000, the chief of which were Zürich (207,161), Basel (135,976), Geneva (135,059), Bern (104,626), Sankt Gallen (70,437), Lausanne (68,533), Winterthur (49,969), and Lucerne (44,029). Bern is the federal capital.

Surface.—The area of Switzerland is distributed over four river-basins—those of the Rhine, the Rhone, the Inn, and the Ticino, a tributary of the Po. The Confederation is bounded on the S. by a part of the main chain of the Eastern Alps, running from south-west to north-east; on the W. and NW. by the Jura; and on the N. by the Rhine. The Pennine Chain of the Alps lies to the south of the valley of the Rhone, on the north of which valley are the Bernese Alps extending from the Lake of Geneva to the Grimsel. East of the Bernese Alps is the St Gotthard group, with its ramifications in the direction of Lucerne and Glarus. The Rhaetian Alps are east of the Pennine Chain. A broad fertile plain extends from the Lake of Geneva to the Lake of Constance. The lowest level on Swiss territory is 646 feet, on the banks of Lake Lugano; the highest is 15,217, the summit of Monte Rosa. The lakes of Switzerland, of which the largest are those of Geneva and Constance, cover an area of some 535 sq. m. There are numerous waterfalls, the highest (1002 feet) being the Staubbach in the Bernese Oberland. The Falls of the Rhine at Schaffhausen are upwards of 80 feet in height, and have been called a 'miniature Niagara.' There are about 470 glaciers, the largest being the Gross Aletsch, 15 miles in length. In Valais a greater surface is covered by glaciers than in any other canton; there are, however, no glaciers in eleven cantons. In the Central Alps the limit of perpetual snow varies from 9250 to 9020 feet.

Geology.—The geological structure, assisted by denudation, gives the country its picturesque character. In the south the chain of the Western and Central Alps consists of a series of crystalline masses lying south-west and north-east, covered on the northern slope by sedimentary rocks belonging to the Triassic, Jurassic, and Cretaceous formations. These coverings of sedimentary rocks are much folded, and overlap, forming limestone cliffs (Wetterhorn, Eiger, Jungfrau, &c.). To the north is the Jura range, a chain of regularly folded and anticlinal hills with longitudinal valleys often intersected by ravines. The wide plateau between the Jura and the Alps consists of Tertiary deposits of sandstone and clay, partly lake and sea deposits; it is covered also by deposits of ancient glacial moraines and gravels of the last glacial epoch. Few metallic deposits are to be found in Switzerland; those which exist cannot be worked owing to the irregularity of the veins. In Valais there are coal-formations metamorphosed into crystalline rocks, the coal being changed into anthracite of very irregular size. Salt is obtained in the valley of the Rhine at Rheinfelden. See ALPS, JURA, &c.

Climate.—In a country where the height above the sea-level is from 646 feet—where the almond, the fig, and the olive ripen in the open air—to 25,217, the region of perpetual snow, there is great variety in the climate. There is a variation of about 34½° in the mean temperature; at Bellinzona it is 54½° F.; at Geneva, 49½°; Interlaken, 48½°; at the Hospice on the Great St. Bernard it falls to 30°, and on the Theodine Pass to 20°.

Race and Language.—The population is predominantly of the Alpine race, with a strong Nordic element especially in the north and centre. About 71 per cent. of the population (in 1920,

2,750,622) speak German; about 21 (824,320) French; about 6 (238,544) Italian; about 1 (42,940) Romansch; while the remainder speak other languages.

Religion.—By the federal constitution liberty of conscience and belief is declared to be inviolable, and the free exercise of worship is guaranteed within the limits compatible with public order and decency. No bishopric can be established in Switzerland without the consent of the Confederation, the order of Jesuits cannot be received in the republic, and the foundation of new convents or religious orders is forbidden. There is no federal church, each canton has its own ecclesiastical constitution and organisation, and the majority of the citizens can dispose of the church funds (derived from a variety of sources) belonging to the canton. The Roman Catholic priests are more numerous than the Protestant clergy, and are under five bishops. About 57 per cent. of the population (in 1920, 2,230,597) are Protestants (mostly Calvinists); about 41 (1,585,311) are Roman Catholics; about 0.5 (20,979) are Jews; while the remainder belong to other faiths, Christian Catholics, &c.

Constitution and Government.—The republic of Switzerland became a federal state (*Bundestaat*) in 1848: previously it consisted of a league of semi-independent states or cantons. The present constitution, based on laws passed in 1848 and revised in 1874, was constructed with the view of satisfying both cantonal and national elements, and is therefore essentially a work of compromise. It is the first constitution which was entirely the work of the Swiss without foreign influence, although its authors studied that of the United States. The political structure of Switzerland is built up in three tiers—the Commune, the Canton, and the Federal Assembly. In the communes, which are the real political divisions of the country, 3164 in all, local matters are administered by two governing bodies—the Communal Assembly, composed of all male citizens who have attained the age of twenty, and the Communal Council, with a president, the executive of the Assembly, by whom it is elected. The communes carry out cantonal and federal decrees, and are mostly grouped together (*Amtsbezirke*) under prefects (*Regierungsstatthalter*) appointed by the cantonal government. Each canton has its own constitution and local government. The constitutions of the several cantons vary considerably, but all are based on the principle of the absolute sovereignty of the people, subject to certain restrictions chiefly regarding military and legal matters imposed by the federal constitution: they are subject also to the ratification of the Confederation. Each canton has its own legislative and executive. In Uri, Unterwalden, Appenzell, and in Glarus there still exists the ancient *Landsgemeinde*, an open-air gathering of all those possessing votes, who meet every spring to legislate on cantonal affairs. The other cantons elect by universal suffrage a legislative body (*Grossrat*), varying in numbers according to the population. The executive (*Regierungsrat*) is elected by popular vote. This executive superintends all cantonal affairs and the government of the communes, and also transacts business with the federal government and with that of other cantons. The supreme legislative authority of the Confederation is vested in a parliament of two chambers, the Council of the States (*Ständerat*) and the National Council (*Nationalrat*), always under reserve of the *referendum* and *initiative* (see next paragraph). The Council of the States consists of forty-four members, each canton having two representatives, and each half-canton one. The regulations as to their election, remuneration, and duration of term of office differ

in each canton. The National Council consists of 198 members, elected by proportional representation in each canton, one deputy for every 20,000 of the population. The electoral districts cannot be made up of parts of different cantons, and are fixed by the Federal Assembly after every census; the election takes place once every three years. Every male who has attained the age of twenty and possesses the rights of citizenship according to the constitution of his canton, is entitled to vote, and any voter other than a clergyman or an official appointed by the Federal Council is eligible for election as a representative. Members are paid at a general rate for every day of attendance, and receive travelling expenses. The Council of States and the National Council each elect a president and vice-president, and meet at Bern, together forming the Federal Assembly (*Bundesversammlung*). The executive authority of the Federal Assembly is delegated to the Federal Council (*Bundesrat*) composed of seven members, elected for a period of three years. Federal councillors cannot be at the same time members of any cantonal or federal assembly, nor must they engage in any trade or business. No canton can have more than one citizen in this council; its duties are divided among seven departments, one member being charged with the direction of each. The Federal Assembly and Council together form the Federal Government, which is supreme in matters of peace and war, and has control over the army, railways, and the postal system. The president of the Federal Council, who is also president of the Confederation, is chosen annually at a united meeting of the Council of the States and the National Council from among the members of the Federal Council. The president and the vice-president (who is chosen at the same time) are elected for one year, and cannot be re-elected within twelve months of the expiration of their term of office, but usually the vice president succeeds the president. The president has no special power in virtue of his peculiar office, his position resembling that of chairman of a board of directors.

Referendum and Initiative.—In 1831 an article was introduced into the constitution of Sankt Gallen, declaring the 'sovereignty of the people, who have the right not only to pass their own laws, but also to veto them.' This paved the way for the referendum, which has now spread throughout the whole Confederation, and by means of which all legislative acts passed in the Federal or Cantonal Assemblies may be referred to the people *en masse*. It is of two kinds, compulsory and optional, both as regards federal and cantonal matters. In some cantons all laws adopted by the representative body of the canton must be submitted to the people; in others it may be demanded by a certain number of votes. Cantonal referendum exists in those cantons where there is no *Landsgemeinde*. In most of the cantons 5000 signatures are required in order to obtain a referendum for cantonal laws. The compulsory referendum regarding federal legislation was established in 1848, but was then limited to the revision of the constitution. That of 1874 contains an article extending the exercise of the popular vote, when demanded by 30,000 citizens or eight cantons, to all laws and resolutions of a general nature passed by the Federal Assembly, this being the optional form of the federal referendum. Since the referendum was fully developed in 1874 it has been put in operation on an average once a year; the decisions have generally shown a conservative rather than a radical tendency on the part of the people.

Initiative is the exercise of the right granted to voters to initiate proposals for the enactment of new laws or for the alteration or abolition of old

ones. By this means 'the sovereign people' have always the power to bring forward the discussion of legislative matters, even in the event of their representatives in the government being unwilling to do so. Fifty thousand signatures are required to obtain the initiative regarding federal legislation, and in the majority of cantons 5000 for cantonal matters.

Law and Justice.—Each canton has its own procedure and system, both for civil and for criminal matters. In the French cantons, with the exception of Geneva, the civil codes are based upon the *Code Napoléon*, while in the German cantons they differ considerably from each other, and are for the most part original. In ten cantons capital punishment exists. By the federal constitution, 'no sentence of death can be pronounced for a political offence.' The Federal Tribunal (*Bundesgericht*) sits at Lausanne, and has original and final jurisdiction in suits in which the Confederation or cantons are concerned, and in cases of a certain importance between individuals; it also acts as a Final Court of Appeal.

Revenue and Expenditure.—In the years immediately after the Great War, debit balances became the rule. The customs, by far the main source of revenue, decreased in amount, while the expenditure, especially that of the army, increased; further, raw products had to be obtained from foreign countries at greatly enhanced prices. Recourse was had to borrowing, but at heavy rates of interest. It is tried to balance the federal budget at about 12 million sterling per annum, but in 1920 the expenditure exceeded the revenue by as much as 4 million sterling. The Swiss currency, however, remained at par. The proceeds of the federal alcohol monopoly are divided among the cantons. Each canton has its own budget of revenue and expenditure and debts. The cantons obtain their revenue more from direct taxation and the Confederation from indirect taxation.

Army.—Military service is compulsory and universal. The army, however, is essentially a citizen force drawn from all classes of the people, being intended only for defensive purposes and to secure the neutrality of the country. It is divided into three classes—the *Auszug*, or *Elite*, in which all citizens are liable to serve from the age of twenty to thirty-two; the *Landwehr*, from thirty-two to forty; and the *Landsturm*, from forty to forty-eight. After the first year, training is limited to a few days annually. The army, which was kept on constant active service during the Great War, numbers altogether about 300,000, but the number of men permanently under arms is very small.

Education.—Primary instruction is compulsory, unsectarian, and provided gratuitously at the cost of each canton, whose officials control the administration and inspection of the schools; thus the details of organisation vary considerably. There are over half a million pupils at the primary schools. There are also secondary, complementary (almost equivalent to extension courses), and higher schools, as well as commercial, administrative, art, technical, and agricultural colleges. There are seven universities on the German model—Basel (1460), Bern, Zürich, Geneva, Lausanne, Fribourg, and Neuchâtel, all with four faculties, except the two last, which have no faculty of medicine. In theology, Fribourg is Roman Catholic; Bern, Christian Catholic and Protestant; and the rest are Protestant. The Polytechnic at Zürich is under the control of the federal authorities, and, inclusive of this technical school, there are nearly 7000 students at the Swiss universities.

Occupations and Industries.—Of the total area of the country, about one-quarter is classed as 'unproductive,' being covered by rocks, glaciers,

lakes, towns, &c., about one-quarter is occupied with forest, about one-third with pasture, and about one-sixth with arable land. There is considerable equality in the distribution of wealth, and it is estimated that there are over 200,000 peasant proprietors. Wheat, vines, and tobacco are cultivated, but quite inadequately for the wants of the people. Cattle-breeding is very important, there being altogether about a million and a half head of cattle in the country. The Swiss possess two excellent breeds, the parti-colored and the dark-brown, the former are amongst the heaviest in Europe, the milk being admirably adapted for making cheese and butter. There are some thousands of cheese-making establishments, and the making of chocolate and condensed milk is also considerable. The forests, once greatly wasted, are now better cared for, and in a great part of the country are under the Federal Government. Many industries flourish in Switzerland, the most important being the textiles, especially silk and cotton. Watch-making (established at Geneva in 1587), embroidery, wood-carving, and brewing are also carried on, there are manufactures of machinery and chemicals, and there is some salt mining. It is estimated that several millions of pounds sterling are brought annually by tourists into the 'Playground of Europe.' The railways, mostly the property of the Confederation, are over 3600 miles in length, and the process of electrification is proceeding rapidly. To dispense with imported coal as much as possible, Switzerland is making a determined effort to utilise her rich water-power.

Commerce.—Little or no coal is to be found in the Confederation, there are no canals or navigable rivers, the country is situated far from the seacoast, and nearly the whole of the raw material and half-finished goods have to be imported. Still, in spite not only of these drawbacks but of the protective policy adopted by the neighbouring powers, there is a larger general trade per head of the population than in almost any other European country. The chief imports are cereals, raw cotton, silk, wool, &c., minerals and iron, and the chief exports, manufactured textiles, dairy produce, machinery, and clocks. Most of the trade is with France, Germany, Great Britain, the United States, and Italy.

History.—Stone implements of Mousterian character (see STONE AGE) have been found at Cotencher and Wildkirchli. Schweizersbild, Kesslerloch, and other stations have yielded bones and artefacts of Upper Palaeolithic Age. The Lake-dwellings (q.v.) bring us from the Neolithic into the Bronze Age (q.v.). At the time of the Roman invasion the two principal tribes in possession of the country were the Celtic Helvetii and the Rætii (of doubtful affinities). In 58 B.C. the Helvetii were partially subdued by Julius Cæsar, but it was not till 15 B.C. that they were completely subjugated by Augustus. These became part of the Roman empire, and during the three following centuries trade was developed and military roads were constructed, e.g. the St Gotthard, the Great St Bernard, and that crossing the Julier. The chief Roman settlements were *Aventicum* (Avenches), *Augusta Rauracorum* (Kaiser Aargau), and *Vindonissa* (Königsfelden). After the conquest of Gaul Helvetia was invaded by the Burgundians and the Alemanni 450 A.D. The former took possession of western Switzerland, and the latter settled east of the Aar, in the district since known as 'La Suisse Romande.' In the 7th century, during the domination of the Frank kings of the Merovingian dynasty, order was restored, and Christianity preached by SS. Gallus, Columbanus, and others. About this period the great monasteries of Einsiedeln, Disentis, Sankt Gallen, and Pfäfers were founded, which soon became

centres of progress and learning. Much of what later became Switzerland then formed part of the Holy Roman Empire, for which it was ruled by wealthy abbots and nobles, among whom were the Counts of Zähringen. This powerful family became extinct in 1218, and the country was distracted by internal wars. In 1273 Rudolph of Hapsburg (whose castle was situated in what is now the canton of Aargau) was raised to the imperial throne; after his death (1291) a short period of anarchy ensued in the empire. The inhabitants of Uri, Schwyz, and Unterwalden then felt the necessity of joining together in order to defend their common interests. The Confederates (*Eidgenossen*) did not, however, throw off their allegiance to the emperor; their hostility was rather directed against the despotic power exercised by the bailiffs or middlemen, some of whose acts of tyranny have been described in Schiller's *Wallhelm Tell*, which is founded on the legends belonging to that period (see TELL). Out of this defensive alliance sprang that pact which constituted the germ of the present Swiss Confederation, but which from 1291 to 1874 has passed through seven distinct phases—viz.:

- (1) The League of the Three Communities, 1291;
- (2) The Confederation of eight cantons, 1353; (3) The Confederation of thirteen cantons, 1513; (4) The Helvetic Republic, 1798; (5) The Act of Mediation, with nineteen cantons, 1803; (6) The Federal Pact, with twenty-two cantons, 1815; (7) The Federal Constitution of 1848, revised in 1874.

In 1307 it is stated that Werner Stauffacher of Schwyz, Walter Furst of Uri, and Arnold of the Melchthal in Unterwalden (representatives of the three leagued cantons) met together in the meadow of Grütli by the Lake of Lucerne, and took an oath to free their soil from the Austrian oppressors. They swore that they would be 'all for each, and each for all,' which still remains the motto of the Confederation. Five years later the Confederates were called upon to vindicate this oath, and defend their country against Leopold of Austria. In 1315, while marching at the head of a powerful army through a defile beneath the heights of Morgarten, he was surprised by the Swiss, who hurled down stones and trunks of trees, completely routing their opponents. In 1332 Lucerne joined the alliance of the Three Communities, and the League was increased to four Forest States or Cantons (*Vierwaldstetten*). Bern and Zürich had become imperial fiefs, and the growing importance of the former excited jealousy in western Switzerland, with the result that in 1339 a large force laid siege to Laupen, but were defeated by the Bernese under Rudolph von Erlach. By 1353 Bern, Zürich, Glarus, and Zug joined the Confederation, which thus attained its second phase of eight cantons. The Austrians were again routed at Sempach in 1386, and in 1388 at Näfels; and subsequently in 1393, with the view of strengthening the federal sovereignty, the confederates drew up the document known as the 'Convention of Sempach.' The Swiss were next engaged in a struggle on the French frontier with Charles the Bold; they defeated him at Grandson in 1475, again at Morat, and finally in 1477 before the walls of Nancy, where Charles himself was slain. The unequal distribution of the booty taken at Grandson and Morat occasioned much jealousy between the five rural states or cantons and the cities of Zürich, Bern, and Lucerne; the dissolution of the Confederation seemed imminent, but owing to the intervention of Nicholas von der Flies an understanding was effected at the Diet of Stanz in 1481, laws were made as to the admission of new cantons, and separate alliances between them were prohibited. By 1513 Fribourg, Solothurn, Basel, Schaffhausen, and Appenzell were

added to the Confederation, this being the third phase of its history. In addition to these were associated and protected states, as well as subject territories, belonging to one or other of the various cantons. Valais, the Grisons, Geneva, Biel, and Mülhausen were republics. The principality of Neuchâtel, the lands of the Abbey of Sankt Gallen, and the bishopric of Basel were ruled by lay or ecclesiastical sovereigns.

The 16th century saw the rise of Protestantism. Zwingli led the van in Zürich, whence the Reformation spread, first to Bern and then northwards; the Forest Cantons, with Zug, Fribourg, and Solothurn, however, remained faithful to the Church of Rome. In 1531 war broke out between the Catholics and Catholics, and at the battle of Kappel, where Zwingli was killed, the Zürichers were defeated by the Forest Cantons. The episcopal and imperial city of Geneva, which had allied itself with Bern and Fribourg against the Dukes of Savoy, became a republic in 1535, and accepted a new civil and ecclesiastical legislation under Calvin. In the following year the Pays du Vaud, long subject to the Dukes of Savoy, was conquered by Bern; the inhabitants became Protestant, and the Reformed doctrines spread into western Switzerland. During the Thirty Years' War Zürich and Bern successfully helped to maintain the neutrality of Switzerland, and by the treaty of Westphalia in 1648 the country was acknowledged by the great powers as an independent state. Bern, since the conquest of Vaud, had become the most powerful canton; the wealthy inhabitants of the city constituted themselves into a close corporation or guild, to which no new members were admitted, and, as in Lucerne, Fribourg, and Solothurn, all official posts were in the hands of the patrician families.

Zürich, Basel, and Schaffhausen were 'semi-aristocratic' cantons, the burghers having a share in the elections, from which, however, the country-people were excluded. The remaining six cantons ruled themselves in the *Landsgemeinden* or popular assemblies. The internal state of the cantons, however, owing in many cases to a tyrannical administration, showed a need of reform. The subject-territories had particularly to complain of the arbitrary conduct of the bailiffs by whom they were ruled, as well as of the inequality which existed between the inhabitants of town and country. It only required the impetus imparted by the French Revolution to produce a wide-spread rising in Switzerland. In 1798 Vaud declared its independence against Bern, and a French army came to her aid. In other parts of Switzerland similar outbreaks occurred; the French routed the troops of the Forest Cantons and those of the Bernese under General von Erlach at Fraubrunnen and Grauholz, the city of Bern was taken, and the ancient Swiss Confederation came to an end.

Till 1798 there had simply been alliances between the different cantons; no real constitution existed, and the establishment of the Helvetic Republic (the fourth phase of the Confederation) was the first attempt at a federal constitution. It was extremely unpopular; not only was it imposed by foreign pressure, but it was against the traditions of the Swiss people. The whole country was torn by two hostile factions till 1803, when Napoleon summoned representatives from both parties to Paris, and gave Switzerland a new constitution, termed the Act of Mediation. Sankt Gallen, the Grisons, Aargau, Thurgau, Ticino, and Vaud were added, making nineteen cantons in all, this being the fifth phase of the Confederation. The downfall of Napoleon brought with it the destruction of his work in Switzerland, whose perpetual neutrality as well as the inviolability of her territory was recognised by the congress of Vienna in 1815.

Valais, Neuchâtel, and Geneva, which had been annexed to France under the Directory, were added to the existing cantons, which thus became twenty-two in number; each of them was represented at a diet which met alternately at Bern, Zürich, and Lucerne. The decline of the Bourbons had, too, its echo in Switzerland; the patrician families lost the ascendancy they had regained at the beginning of the century, and many of the cantonal constitutions were revised, with the result that the power of the people was greatly increased. Basel, in spite of armed demonstrations, refused to grant proportional representation, with the result that the canton was divided into two half-cantons.

Religious troubles were added to these political disputes. In Aargau, where the grand council was composed of Protestants and Catholics in equal numbers, the constitution was altered upon a basis of popular representation by which the Protestants gained numerical advantages. In 1841 two thousand Catholic peasants took up arms, but were beaten by the Protestants at Villmergen; eight convents were suppressed, and much valuable property confiscated. The democrats gained ascendancy in Geneva, and in 1842 the same party obtained the upper hand in Valais. In 1844 the grand council of Lucerne entrusted the Jesuits with the direction of public instruction, with the result that the town was attacked by bands of volunteers, who demanded the expulsion of the priests. In defiance of the Federal Pact, Lucerne called to her aid the Forest Cantons, Zug, Fribourg, and Valais, together forming what is known as the *Sonderbund*, whose members declared that they would preserve this 'separate league' till the convents were re-established and the question of the Jesuits abandoned. In 1847, after the deputies of the *Sonderbund* had left the Diet, it was resolved to dissolve by force of arms this league of the Catholic cantons. The federal army under General Dufour consisted of 50,000 men, the Catholics brought about half that number into the field, and after a campaign of twenty-five days Fribourg was taken, Lucerne and the smaller cantons capitulated, and the struggle came to an end. No sooner had the *Sonderbund* been dissolved than it became necessary to revive the Federal Pact, and a constitution was adopted for the whole of Switzerland, this being the seventh phase. Owing not only to the development of commerce and industry, but to the difference between the legislature in the cantons, it became necessary in 1874 to revise this constitution, and since then it has been added to and altered. During the Great War, Switzerland performed a large amount of relief work for the prisoners and wounded of all countries, and at the same time suffered very considerably from food shortages. Her position between the entente and the central powers was extremely embarrassing for her, as she depended so largely on supplies from foreign countries. This geographical position of Switzerland, her special constitution, and the possession of three 'official' languages (German, French, and Italian), makes the country peculiarly international. Much foreign money is invested in Swiss banks, tourists and political exiles instinctively turn to Switzerland, and international organisations such as the League of Nations, the Red Cross, the International Postal and Telegraph Union have their seats in Swiss territory (see GENEVA).

Literature.—The literature of Switzerland, save the unimportant part that falls under Romansch (q.v.) or Italian, is included either in German or in French literature: Bodmer and Gessner are as certainly names of mark in German literature as Rousseau or Chénobuz in that of France. Here it may therefore suffice to give the names of

Swiss writers, most of whom are treated in separate articles: thus to the German division belong Zwingli, Bullinger, Tschudi, Bodmer, Gessner, Zimmermann, Haller, Lavater, Pestalozzi, Johannes von Müller, Füssli, Bitzins, Keller, Meyer, Spitteler, Schaffner, Pulver, and Steffen; to the French Bonivard, Rousseau, Vattel, Bonnet, Benjamin Constant de Rebecque, Bonstetten, Sansure, Sismondi, Necker (and by origin his daughter Mme. de Staël), Dumont, Töpffer, Vinet, Chénobuz, Amiel, and Rambert. Calvin and Beza, Voltaire and Gibbon were resident in Switzerland for varying numbers of years. The Swiss-German of the country people is a High German patois.

See ALPS, ALPINE CLIMBING, MERCENARIES, SWISS GUARDS, articles on the different cantons and towns, on mountains, passes, and tunnels, on prominent Swiss historical characters, and the books there cited. For the topography of Switzerland, see the *Dictionnaire Géographique* (also in Ger., 6 vols. 1902-10); various guide-books, &c., by Coudage; for geology, books by Heim (in Ger. 1919 *et seq.*); for flora, Schinz and Thellung (1923); for travel, Wäber (in Ger. 1909); for general information and social life, Dauzat, *La Suisse Illustrée* (1914); books in English by Story (1922), Welch (1909), and Atherton Hill (1924); and in German by Heer (1902) and Lifshütz (1924); for economics, books by Clerget (in Fr. 1908) and Schmidt (in Ger. 1914); for the constitution generally, various works by Schollenberger, especially his *Kommentar mit Einleitung* (1905); various works by Curti, including his *Geschichte* (1885); books in French by de Salis (also in Ger., new ed. 1902), in English by Vincent (1900), Bonjour (1920), and Brooks (1920), and in German by Heusler (1920) and Frauchigee (1922); for the referendum, books by Hymens (in Fr. 1892) and Stüssi (in Ger. 1893); for the history, various works by Oechsl, including his *Quellenbuch* (new ed. 1918) and his *History, 1499-1914* (Eng. trans. 1922); works by Dietauer (in Fr. and Ger., 5 vols. 1911-17), van Muyden (in Fr., 3 vols. 1890-1901), Gagliardi (in Ger., 2 vols. 1920), and in English by Hug and Stead (new ed. 1920) and Cameron (1918); for the literature, the general histories by Hächold (in Ger. 1892), Rosel and Jenny (in Fr. 1910), Godet (in Fr. 1889); for contemporary writers, Korodi, *Die Junge Schweiz* (1921); *Anthologie Helvétique*, ed. Faesi (1921), an anthology of Swiss writings of all types and periods, including some in patois.

Swoon. See FAINTING.

Sword. A weapon of offence consisting of a blade fitted into a hilt or handle, with a guard, the blade being formed to cut or to pierce, generally to do both. The sword is the most highly honored of all weapons, a symbol of military dignity and authority; and it is the instrument with which the monarch confers knightly honours. Its forms and modifications, and the names under which, in different shapes, it has been known in different lands, and in successive ages, are beyond computation. It is sufficient to say that the general term includes weapons so diverse as the short cutting and piercing daggers and poignards and the ponderous two-handed swords of the 15th century. The blade may thus vary in length from a few inches to four feet and upwards. It may be furnished with a cutting edge on one side only, or on both sides. It may be uniform in breadth throughout with a truncated end, or it may taper from the hilt to a fine point. The blade, moreover, may have a piercing point alone, as in the rapier, and it may be curved

Fig. 1.

throughout its entire length, as in the oriental scimitar. The hilt, with its many forms of guard, grip, and pommel, similarly adds to the variations of the weapon.

The sword, of course, could not be a weapon of primitive man; but it is easy to trace its develop-

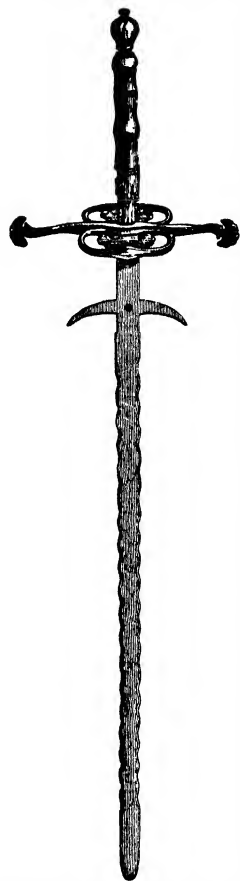

Fig. 2.—Two-handed Sword, preserved in Duff House.

ment from the forms of weapon in use in the Stone and early Bronze Ages. The sword came into use only when men had attained considerable skill in casting and working bronze, and the ancient bronze swords, many of which have been found throughout Europe with two-edged blades measuring two feet in length, are well finished weapons (see BRONZE AGE). The early Greek sword (fig. 1, *a*) was merely a strong two-edged knife; but about 400 B.C. its form was improved and its size doubled by Iphicrates. The *gladius* of the Romans (fig. 1, *b*) was still of the same form—a straight two-edged blade, heavier and longer, however, than the Greek weapon. During the early middle ages there does not appear to have been much development in the form of the sword in Europe. As shown by the Bayeux Tapestry (q.v.) and other contemporary representations, it continued to be a short cutting weapon, with a blade of uniform breadth bluntly pointed, and to give it balance it was channelled from the hilt for about two-thirds of its length. The cross-guard, subsequently called the quillons, was short, projecting at right angles from the blade, but sometimes bent forward in the direction of the point. With the development of armour in warfare it became necessary to give much greater heaviness and strength to the sword; the blade was greatly lengthened and tapered from hilt to point, the guard and the hilt were also lengthened, and in this way the two-handed sword—the distinguishing arm of the 15th century—was evolved. In Scotland several of these ponderous weapons are preserved, and traditionally associated with the names of Wallace, Bruce, and other contemporary heroes; but such swords were really not in use so early a period. So late as 1567 Lindsay proposed to meet Bothwell in single combat at Carberry, armed with ‘the famous two-

handed sword of Archibald Bell-the-Cat.’ With the introduction of the two-handed sword, the use of a shield being no longer possible, the guard gradually became more complicated, so as to give greater protection to the hands of the swordsman, and from the use of shell-guards and ring-guards, &c. the basket-hilt, as applied to lighter swords, by degrees developed. The ordinary basket-hilt sword, such as is worn by officers of Highland regiments at the present day, is of Italian origin, and grew out of the Venetian *schiarone*. The rapier—a piercing weapon only, with a blade tapering to a fine point—came into use in the early part of the 16th century, and in the 17th century it became the weapon of fencing and duelling. From very early times Toledo, Seville, and some other Spanish towns had a high reputation for the excellence of the swords made by their armourers, and when to their own skill was added the perfect craftsmanship of their Moorish conquerors the renown of Spanish blades became supreme. In the North Italian towns also, as well as at Solingen and Passau in Germany, swords of famous quality were fabricated. In Scotland during the 17th and 18th centuries Ferrara blades were held in the highest esteem, and were a very common possession. Who the original maker of these famous blades was is not known, but in the 16th century there was a family of armourers named Ferrara (q.v.) in North Italy, one member of which, called Andieu, was born in 1555. It is, however, obvious from the long period over which the manufacture extended that ‘Ferrara’ became more a trade mark than a maker’s name. Many magnificently finished examples of swords from the Renaissance period downwards are preserved as art treasures in public and private collections. On the enrichment of

these the highest efforts of artificers and artists have been expended, and they have been lavishly adorned with gold enamels and precious stones. Additional interest is given to some of these swords by the legends attaching to them, and by the historical importance of the personages to whom they belonged. Mythical stories are also numerous of craftsmen endowed with marvellous powers, and with whose blades unheard-of feats could be performed. In modern warfare the sword possesses little more than an honorary military significance.

See DAMASCENING, and, besides works cited at FENCING and DUELLING, James Drummond’s *Ancient Scottish Weapons* (1881), Sir R. Burton’s *Book of the Sword* (1884), Sir F. Pollock’s *Oxford Lectures and other Discourses* (1891), various books by A. Hutton, including *Swords and Centuries* (1901), and Nimier and Laval, *Les armes blanches* (1906).

Sword-fish (*Xiphiidae*), a family of spiny-rayed Teleostean fishes, abundantly represented in

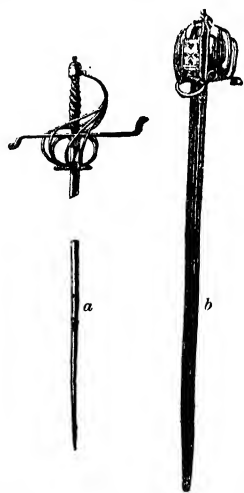

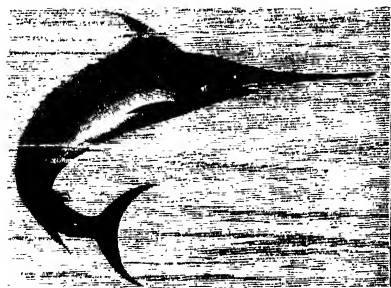

Fig. 3.—*a*, Rapier, 16th century; *b*, Basket-hilted Ferrara.

tropical and subtropical seas. They are among the largest bony fishes, sometimes measuring 12 to 15 feet in length. The sword, which may be over 3 feet long, is formed from a compressed prolongation of the upper jaw, and is often strong enough to stab whales fatally, or less advantageously to pierce the bottom of a ship or the planks of a boat. The genus *Xiphias* is well represented by the common sword-fish (*Xiphias gladius*), abundant in the Mediterranean and in

Common Sword-fish (*Xiphias gladius*).

the warmer parts of the Atlantic and Pacific, and of rare occurrence on British coasts. They are found in schools, but never in close company; they feed on such fishes as mackerel, menhaden, and herring, which they kill with the sword, and also it seems on cuttle-fish. The flesh is somewhat oily, but is highly esteemed, both fresh and salted. With the regular sword-fish fishermen, harpooning is the mode of capture. The genus *Histiophorus*, the members of which are also called sail-fishes or bill-fishes, has a greatly developed dorsal fin or sail, and has long, compressed ventral fins which are absent in *Xiphias*. As in the true sword-fish, the young, with undeveloped swords, are very different from the adults. In summer *Histiophorus* occurs in the American seas as far north as New England, but it is strictly a tropical fish. Another form—the spear-fish—of similar distribution, is generally referred to a distinct genus, *Tetrapturus*. The only sword-fishes must not be confused with the cartilaginous Sawfishes (q.v.) belonging to the Elasmobranch genera *Pristis* and *Pristiophorus*.

Sybaris, an ancient city of Magna Græcia, stood on the Gulf of Tarentum, and was founded about 720 B.C. by colonists from Achæa and Træzene. The fertility of its soil and its liberal policy favoured commerce, and the city flourished and became very prosperous. Its citizens led such luxuriant and self-indulgent lives that their name became a by-word amongst the peoples of antiquity. Quarrels between the democratic and oligarchic factions led in 510 B.C. to a war with the neighbouring colony of Crotona (q.v.), in which the forces of the Sybarites were totally routed, their city captured, and the site where it stood obliterated by the victors, who turned upon its ruins the waters of the adjacent river Crathis. Excavations have so far failed to give any precise knowledge of its topography; all that has been found is two cemeteries, one of the early Iron Age, the other of 400 B.C.—the latter belonging to the period when Thuri (q.v.) was at the height of its prosperity.

Sybel, HEINRICH VON, German historian, was born at Düsseldorf on 2d December 1817. Perhaps the most eminent of Ranke's pupils, he became

successively professor of History at Bonn (1841), Marburg (1846), Munich (1856), and Bonn again (1861), in Munich also filling the post of secretary to the Historical Commission of the Royal Academy of Sciences. At various times between 1848 and 1880 he sat in the parliaments of Hesse, the North German Confederation, and Prussia, as a National Liberal and an opponent of the Ultramontanes. In 1875 the Prussian government made him director of the state archives at Berlin; and as such he was instrumental in publishing the *Political Correspondence of Frederick the Great*, and in organising at Rome a 'Prussian station for Researches in German History,' besides assisting in the publication of the *Monumenta Germaniæ Historica*. Moreover he founded and edited the *Historische Zeitschrift*. Sybel's first book was a history of the First Crusade (1841), in which, applying the critical methods of his master, he destroyed the accepted opinions of centuries; his next the *Entstehung des deutschen Königthums* (1844). Then, after an interval of nine years, came his first masterpiece, *Geschichte der Revolutionszeit von 1789 bis 1795* (3 vols. 1853-58; 4th and greatly improved ed. 1877), a cool, sober, and dignified statement of the historic causes and consequences of that eventful period, based upon a critical examination of official documentary evidence. A second part or continuation, bringing the narrative down to 1800, was published in 2 vols. in 1872-74. His second great work is entitled *Die Begründung des deutschen Reichs durch Wilhelm I.* (5 vols. 1889-90; English trans., New York, 1891), exhibiting the same qualities. Von Sybel, who also published three volumes of *Kleine Historische Schriften* (1863-81), died at Marburg, 1st August 1895.

Sycamore (*Ficus Sycomorus*) is a large tree, ranging from Syria through North Africa to the Cape Verde Islands, often planted near villages for the sake of its shade, its wide spreading head sometimes covering a space 40 yards in

Branch of *Ficus Sycomorus* :
a, fruit.

diameter. The figs are top-shaped, and grow in clustered racemes on the trunk and oldest branches. Inferior to the common fig, they are nevertheless sweet, well flavoured, and somewhat aromatic. The wood is light, porous, and of little value.

The sycamore-tree of England is a species of Maple (q.v.), and in Scotland is usually called plane-tree (though neither plane nor sycamore). In some parts of North America the name of sycamore is given to the Plane (q.v.) of that country, *Platanus occidentalis*.

Sycosis, a pustular eruption on the bearded part of the face, due to Ringworm (q.v.), Acne (q.v.), or Impetigo Contagiosa (q.v.).

Sydenham, a district in the metropolitan borough of Lewisham, is of world-wide celebrity in connection with the Crystal Palace, which, however, is really outside the county of London, on the borders of Surrey and Kent. It was erected

in 1852-54, chiefly from the materials of the building of the Great Exhibition (1851), and under the superintendence of Sir Joseph Paxton. The cost of the erection and appointment of the Crystal Palace amounted to nearly £1,500,000. The building is 1608 feet long, 390 wide across the transept, and 175 feet high, the height of the two water-towers being 282 feet. The chief arts and sciences are illustrated by collections within the Palace and in its grounds. There are two concert-rooms, within the larger of which on occasion of the triennial Handel festivals (since 1859) performances have taken place with 4000 vocalists and instrumentalists. The park and gardens occupy nearly 200 acres, and are adorned with sculptures, stone balustrades, &c., and fountains which are perhaps the finest in the world. Cricket and football matches and other sports are held in the grounds. On 30th December 1866 there was a fire in the north wing, doing damage to the amount of £150,000. The palace, whose finances have more than once been seriously embarrassed, was offered for sale in 1911, and acquired by the public in 1913-14.

Sydenham, FLOYER (1710-87), an amiable man of letters whose privations brought about the foundation of the Literary Fund, graduated at Oxford, and in his fiftieth year began the publication of an excellent translation of Plato's *Dialogues*. It had no market, neither had his dissertation on Heracitus (1775) or his *Onomasticon Theologicum* (1784). Arrested for unpaid meals, he died in prison.

Sydenham, THOMAS, the 'sommo Ippocratista inglese' (supreme English Hippocratist), as Puccinotti styles him, was born in 1624 at Winford Eagle in Dorsetshire, and died in London, 29th December 1689. That he belonged to one of the county families; that at eighteen he was entered at Magdalen Hall, Oxford; that his studies were, after two years, interrupted by his having to serve as an officer in the parliamentary army; that his Oxford curriculum ended in 1648 when he graduated M.B., and shortly after became a Fellow of All Souls—is the sum of our knowledge as to his youth and early manhood. For the next fifteen years we lose sight of him, though he probably spent some of them at Oxford, if not also at Montpellier. We find him in London in 1663 as a licentiate of the College of Physicians publishing his *Methodus Curandi Febres* in 1666; and ten years thereafter taking his M.D. at Pembroke Hall, Cambridge. With the College of Physicians, or even with Oxford, he seems to have had no subsequent connection; and all through his life he was not a *persona grata* with the faculty. The 'Intro-physical' and 'Chemiatic' theories in fashion at the time he treated with scant consideration, and looked upon chemistry itself as a mere branch of the apothecary's business. But from his intimacy with John Locke and Robert Boyle we might infer his appreciation of the true philosopher and the true physicist, even if we did not know his profound mastery of the Hippocratic method and his perfect assimilation of the Hippocratic spirit. In 1668 he published a second edition of his book on fevers, adding to it a chapter on plague, with a fine poem in Latin elegiacs addressed to him by Locke. A third and enlarged edition, entitled *Observationes Medice*, appeared in 1676. In 1680 he published two *Epistolæ Responsivæ*, the one 'On Epidemics,' and the other on the 'Lues Venerea.' His *Dissertatio Epistolaris* on confluent smallpox and hysteria (1682) was followed next year by his yet more famous *Tractatus de Plaga et Hydrops*. In 1686 appeared his *Schedula Manitoria de Novæ Febre*

Ingressu, and in 1692 his last work, *Processus Integri*, an outline of pathology and therapeutics. An acute attack of gout carried him off in his sixty-sixth year, and he was interred in St James's Church, Piccadilly, where in 1810 the College of Physicians erected a mural tablet to his memory.

Sydenham's place in the history of medicine has already been given. Seemingly behind his age in science, he was really ahead of it in practice. The new-born anatomy and physiology had with premature confidence lent itself to theories, mathematical and chemical, which were utterly at variance with the phenomena of disease as noted at the bedside. He soon satisfied himself that it was hopeless to reconcile them, and that meanwhile, with practical English sense, it was his business to get his patients well. In acute disease he read the forth-putting of that activity by which nature sought to right herself—an activity to be watched and, when possible, to be assisted. Called in to a patient who had been deplorably reduced by lowering treatment, he reversed the practice and 'ordered a roast chicken and a pint of canary.' Chronic diseases he also viewed with the eye of Hippocrates, as due to habits or errors for which we ourselves are mainly responsible, and those he met by appropriate changes in diet and mode of life. The Hippocratic 'natural history method' of looking at and treating ailments of all kinds it was his great merit to have intelligently revived. Among special contributions to nosology he may be said to have first diagnosed semitina and classified chorea, while Puccinotti claims for him the title of 'restorer of the curative treatment of small-pox.' Gout was another ailment on which he left a memorable mark. It was as a practitioner, however, that his powers worked most freely and most felicitously.

See the various histories of medicine; Dr W. A. Greenhall's admirably edited *Opera Omnia* of Sydenham, with Dr R. G. Latham's rendering (both published by the Sydenham Society, founded in 1843); *Select Works* (ed. Dr J. M. Comrie, 1924); Dr John Brown's *Locke and Sydenham; Life* by Newman (1924).

Sydney, the capital of New South Wales and the oldest city in Australia, is situated on the shores of Port Jackson, a deep inlet of the Pacific Ocean. The city was named after Thomas Townshend, first Viscount Sydney (1733-1800), who was Secretary of State in charge of the Colonies when the first British settlers reached New Holland. It had been intended to make the first settlement on the shores of Botany Bay (q.v.). But Captain Phillip, who was in command of the expedition, perceived the unsuitability of this site directly he sailed into the bay; without troubling to put his party ashore, he made search along the coast to the north, and soon discovered the inland trend of Port Jackson, which Cook had thought to be a mere shallow cove like so many others along that coast. After a short exploration Phillip hit on a good stream of fresh water flowing into the deep inlet which he named Sydney Cove; and there, on 26th January 1788, he landed his expedition. The choice was both judicious and fortunate. There are few harbours in the world better fitted physically to be the sites of great commercial cities. Port Jackson is completely landlocked, accessible from the ocean by a passage a mile wide between North and South Head, from which it immediately bends southwards behind a high ridge before extending some fourteen miles westwards. From the main inlet smaller channels are thrown off like veins in a leaf to north and south, each similarly sheltered by high land which sometimes rises 200 or 300 feet above the water. No streams of any size flow into the harbour, so that no difficulty is experienced in keeping a channel of any

requisite depth. The narrow entrance might easily be made inaccessible to a hostile fleet, and the high cliffs on either side give stations for batteries which could ward off any bombardment of the inhabited quarters within. Moreover, Sydney's central position as regards the western Pacific makes it necessarily the chief emporium of both British and foreign trade with the islands of that ocean. Again, Sydney stands nearly in the centre of a great carboniferous basin about 500 miles long and 80-100 miles broad. A hundred miles north of the city, and about 40 miles south of it, are two important coalfields, and immediately underneath the harbour workable seams have been reached by a shaft over 3000 feet deep.

While thus admirably suited for the needs of overseas trade, Port Jackson is by nature ill-adapted to serve the country inland; the small area of farmlands immediately adjacent to it is cut off from the rest of the State by a wide extent of barren ridges to north, west, and south, over which (for, owing to their geological formation, there are practically no passes through them) must be hauled every ton of goods or produce sent from or to Sydney. Being, however, the official centre of the colony from the beginning, the whole transport system of New South Wales was made to converge on it at all costs, both roads and railways being constructed for many, sometimes hundreds of, miles parallel with the coast in order to concentrate trade on this single harbour. This, while acting often as a serious handicap on the progress of the colony, greatly aggrandised Sydney; in 1861 it absorbed 27 per cent. of the total population, in 1891, 34 per cent., and in 1925, 45 per cent. Great endeavours are now being made both to divert population to the farmlands and to decentralise trade by establishing ports at intervals along the sea-coast to which the produce of the interior can be sent more easily and cheaply. It is therefore probable that the city's growth in future will be slower, and less at the expense of the country; but nothing (except, perhaps, a general increase in the size of trading vessels above the draught of 40 feet which at present governs the inner entrance to the port) can displace Sydney from its position as the most important commercial centre of the Commonwealth, especially as the advent of Federation with a fiscal policy of protection has greatly altered the character of its business. Before Federation, Sydney was mainly a collecting and distributing centre, a town of warehouses, offices, and banks; it is rapidly becoming a great manufacturing centre, and the number of factory employees practically doubled between 1900 and 1910—the most important increases having taken place in the clothing, machinery, and furniture factories. To this is due the abnormal expansion of the city in recent years.

Sydney's municipal arrangements are confused, the inhabited area being divided among 41 governing bodies without any central control. The City Council controls a central area of about 3000 acres; the other councils divide among them about 115,000 acres. The principal suburbs are: on the east, Darlinghurst, Paddington, Woolahra, Waverley, Randwick, and Coogee; on the south, Redfern, Waterloo, Botany, Rockdale, and Kogarah; on the west, Newtown, Petersham, Ashfield, Burwood, and Canterbury; along the upper harbour, Balmain, Leichhardt, Drummoyne, Hunter's Hill, and Gladesville. On the ridges north of Port Jackson lie Mosman, North Sydney, and Willoughby-Chatswood. Manly, still farther away beyond the northern branch of the harbour, lies along the ocean beach.

The water-supply of Sydney is derived from a catchment area of 347 square miles on the upper Nepean and its eastern tributaries. Four large

dams (Cataract, holding over 20 thousand million gallons; Cordeaux, about the same; Avon, 47 thousand million; Nepean, 11½ thousand million, incomplete) conserve the flow due to a rainfall of 48 inches per annum, which is conveyed by tunnel, canal, and aqueduct to the Prospect reservoir (11 thousand million gallons) about 22 miles from the city, and thence by canal and pipes to distributing reservoirs at Potts Hill (for Sydney and the southern suburbs) and Ryde (for the northern suburbs); the water is used for domestic purposes without either filtration or chemical treatment. The average daily consumption is about 45 gallons per head, but the maximum reached in 1926 was 99 gallons daily during an exceptionally hot summer. Water-supply and sewerage are under a special board, which controls 3324 miles of water-mains and 1358 miles of sewers. Gas is provided by two private companies, one south of the harbour and the other north; electric light in the city is a municipal enterprise, but some of the suburbs prefer private companies. Parks and open spaces abound; the principal are the Domain (90 acres), Hyde Park (43 acres)—both within the city limits—Moore Park (260 acres) and Centennial Park (640 acres). About 12 miles north is Kuringgai Chase, and about 18 miles south National Park, both reserves of wild bush about 35,000 acres in area. The old military reserves on the harbour cover about 2000 acres more, and the government is steadily resuming strips of 100 feet in depth along the harbour foreshores wherever private buildings do not already occupy the space. The larger ocean beaches at Manly, Bondi, and Coogee are devoted to surf-bathing, which is directly encouraged both by the municipalities and by the government. Evening amusements are catered for by six theatres and two music-halls, besides numerous cinematograph halls. For more serious tastes are provided the public library, the Mitchell Library (housing a unique collection of books and manuscripts concerned with Australia, to the gathering of which the late Mr D. S. Mitchell devoted a lifetime, besides endowing the library with £70,000 at his death), a municipal lending library, a technological and other museums, botanic and zoological gardens (the latter with open pits and terraces for the animals instead of cages), musical, orchestral, historical, art, Linnean and other societies, and many important clubs.

Among the public buildings worth special notice are Government House, a building in Elizabethan style, overlooking the harbour east of Circular Quay; Parliament House, old and commonplace, and flanked on either side by the much more imposing Sydney Hospital and the Mitchell Library; various government offices, mostly bordering on Bridge Street, which connects the central business quarter of the city with Government House grounds; the post office in Martin Place, and the series of fine banks and other private offices which face it; the Queen Victoria Markets, and the Town Hall. In the Domain stand the Conservatorium of Music and the National Art Gallery, a building carefully designed for its purpose, containing a good collection of paintings; outside the gates of the same park is the Roman Catholic cathedral, finely built and nobly placed; farther on is the Australian Museum. But the best architecture in Sydney, or in Australia, is to be found at the university, which is built along a ridge between two main roads at the city's western limit, with six affiliated colleges (Anglican, Presbyterian, Roman Catholic, Wesleyan, Women's and Teachers') on the curve of a farther ridge behind it. The front of the main building is 410 feet long, and the Great Hall at its northern end (135 feet by 45 feet, with an open-timbered roof 70 feet high)

is a fine specimen of true Perpendicular Gothic. At the southern end is the Fisher Library, an equally fine three-storied building of similar design; and the Medical School, of less ornate type, stands farther south on the ridge. For an account of the university as a teaching body, see NEW SOUTH WALES.

The city proper, a long, narrow area stretching south from Sydney Cove (now called Circular Quay) and west to the next bay, Darling Harbour, is nowadays entirely devoted to business. The great wharves lie along the two bays just mentioned and a third, Woolloomooloo Bay, about a mile east of the Quay. The six miles of shore and highland between Sydney and the 'Heads' are covered with residences, mostly belonging to the richer part of the community; opposite, along the north side of the harbour, are more residential suburbs, gradually extending and rising along a ridge north-west to a height of 600 feet at Hornsby, 12 miles away; immediately south of the city proper begin the manufacturing districts of Waterloo and Botany, the latter reaching to the shores of Botany Bay; and westwards again another series of residential suburbs covers lower ridges for a distance of nearly fourteen miles, with a second manufacturing centre at Clyde and Granville before the end of urban habitation is reached at Parramatta. Yet a fourth residential area lies along the western shore of Botany Bay, and on the heights between the two rivers—Cook's and George's—which flow into it. The huge proportion of the total area devoted to residences is accounted for by the fact that the favourite type of habitation is a one-story cottage of four to six rooms standing by itself in a small plot of ground. The mass of the artisan population is thus accommodated; and the consequent dispersal over more than 150 square miles of the people whose day's work lies concentrated in two or three very small patches of that area, while it adds much to the comfort of the worker, adds also very much to the difficulties of transport within the area. Although already served by more than 80 miles of suburban railway, nearly 200 miles of electric tramway, innumerable autobuses, and harbour ferries traversing fifteen routes and calling at over seventy wharves—the railways and tramways belong to the State, the other means of locomotion to private companies or individuals—the traffic is so congested that it has become necessary to spend huge sums on an underground railway through the city (the whole of the tunnels being hewn in the solid rock) and on a steel arched bridge across the harbour which will exceed in dimensions all existing bridges of the kind, so that its construction involves new problems in the use of structural steel. The harbour and its foreshores within the commercial area are under the control of the Sydney Harbour Trust, which has reorganised and considerably increased the wharf space and constructed many jetties of the most modern type. All the new wharves and most of the older are connected with the main railway lines, and wheat may be loaded from up-to-date silos. Unfortunately in the course of these improvements one of Sydney's most notable advantages as a passenger port has been done away with. Whereas a few years ago all the important mail-steamer landings their passengers on Circular Quay, in the very centre of the city amid beautiful surroundings, nowadays one lands on well-equipped but cumbersome jetties in Woolloomooloo Bay, out of which both passengers and cargo must be hauled up steep hills to the city's outskirts.

Garden Island in Port Jackson, for many years the headquarters of the British navy in the Pacific, is now the home station of the Australian squadron of the Imperial navy. Cockatoo Island, farther

up the harbour, is also Federal territory, and several ships of the squadron—both cruisers and destroyers—have been built there.

See AUSTRALIA, NEW SOUTH WALES, and books mentioned thereunder. The Harbour Trust and the Water and Sewerage Board publish handbooks full of detailed information in their respective spheres.

Sydney, a town with an excellent harbour on the east coast of Cape Breton Island, Nova Scotia. There are large iron and steel works, foundries, and wood factories. Over 5,000,000 tons of coal are produced annually from the neighbourhood, and there is a considerable foreign trade. Pop. 22,500.

Sydney, ALGERNON. See SIDNEY.

Syene. See ASSUAN.

Syenite, a rock composed essentially of orthoclase and a ferromagnesian mineral, usually homblende. It is crystalline, having the same texture as a granite. Quartz is sometimes sparingly present, and other accessory minerals may occur, such as oligoclase, sphene, zircon, apatite, ilmenite, &c. *Elæolite-syenite* is characterised by the presence of elæolite—a nepheline with greasy lustre. Syenite is an igneous rock of deep-seated origin, occurring in the form of bosses and veins. It is not common in the British Islands, but several interesting varieties occur in Sutherlandshire.

Sylhet (*Srihatta*), a British district in the extreme south of Assam (q.v.), partly a rich alluvial tract with tea gardens, but partly uncultivable waste, has an area of 5388 sq. m. and a pop. of 2,541,000. The chief town, Sylhet, on the Surma River, has a pop. (1921) of 16,912, and some trade and manufactures.

Sylla. See SULLA.

Syllabus, a culinary preparation, formerly much used, consisted of sugar and cream, flavoured with brandy, sherry, and lemon rind and juice, worked into a froth, and served in glasses. White of egg and verjuice seem also at times to have been ingredients.

Syllabus, a term from the Greek usually applied to a compendium or abstract of a lecture or series of lectures, is specially used of the papal syllabus which accompanied the Encyclical (q.v.) *Quanta Cura*, addressed by Pius IX. to all Catholic bishops on 8th December 1864. This syllabus is a catalogue of eighty errors or heresies, and implicitly enjoins the opposite truths; and by Protestants has generally been regarded as a declaration of war against all freedom of thought, modern civilisation, and social progress, and a reassertion of the extravagant claims of the mediæval papacy to supreme authority on every subject. The syllabus is divided into ten sections, condemning (1) pantheism, naturalism, thorough-going rationalism; (2) milder rationalism; (3) latitudinarianism; (4) socialism, communism, secret societies, &c.; (5) errors as to the rights of the church; (6) as to the constitution of society; (7) as to ethics; (8) as to marriage; (9) as to the temporal power of the pope; (10) the errors of modern liberalism. The infallibility of the pope is indirectly asserted, as is the right of the Roman Catholic Church to exercise complete control over education, literature, and science. Catholics have debated amongst themselves whether the syllabus is an *ex cathedra* papal utterance, and so to be regarded as *de fide* and infallible. The syllabus of Pius X. issued in 1907 in condemnation of 'modernism' in biblical criticism and of liberal theology is a continuation of that of 1864, and was levelled primarily against Père Loisy (q.v.).

See Gladstone's *Vatican Decrees* (1875); Manning's reply, and his *Letter to the Duke of Norfolk*; and Gladstone's answer in *Vaticanism* (1875).

Syllogism. See LOGIC.

Sylphs, in the fantastic system of the Paracelsists, are the elemental spirits of the air, just as the salamanders are of fire and the gnomes of earth. They hold an intermediate place between immaterial and material beings. They eat, drink, speak, move about, beget children, and are subject to infirmities like men; but, on the other hand, they resemble spirits in being more nimble and swift in their motions, while their bodies are more diaphanous than those of the human race. They also surpass the latter in their knowledge, both of the present and the future, but have no soul, and when they die nothing is left. In form they are ruder, taller, and stronger than men, but stand nearest to them of all the elemental spirits, in consequence of which they occasionally hold intercourse with human creatures, being especially fond of children and of simple harmless people; they even marry with our race, like the Undines and the Gnomes, and the children of such a union have souls and belong to the human race. In common usage the term sylph is applied to a graceful maiden—a change of meaning probably owing to the popularity of Pope's *Rape of the Lock*, which introduced the term into the world of fashion and literature. For although even in Pope the sylph that guards Belinda is masculine, yet the poet so refined and etherialised his spiritual agents that they soon came to be identical with ideas of feminine grace and beauty.

Sylt, a narrow island, 23 miles long, off the west coast of Sleswick. The inhabitants (Frisians) decided by plebiscite in 1920 to remain German citizens.

Sylvester, name of three popes—**SYLVESTER I.** (314-335) is claimed to have baptised Constantine the Great, and to have received from him the famous Donation. He was canonised, his day falling on December 31.—**SYLVESTER II.**, whose name was Gerbert, was born at Aurillac in Auvergne about 945, and early acquired from his extraordinary attainments in philosophy, but especially in mathematics and chemistry, the reputation of being in league with the Devil. Made abbot of Bobbio by Otto II., he became secretary to Adalbero, Archbishop of Reims, whom he succeeded in the archbishopric in 991. He was made archbishop of Ravenna in 998 and pope in 999, being the first Frenchman to wear the tiara, and died in 1003. The importance of Gerbert is threefold; in philosophy, he can be called one of the founders of the scholastic movement; in mathematics, he was one of the earliest links between the Arab and Western civilisations; in politics, he had enormous influence over the youthful and visionary Emperor Otto III., and encouraged him in his dreams of a true intimate union at Rome of the temporal and spiritual authorities. See various editions of his *Letters*.—**SYLVESTER III.** (1044-46), Anti-pope to Benedict IX., was set aside at the Synod at Sutri.

Sylvester, JAMES JOSEPH, mathematician, was born in London, 31 September 1814, studied at St John's College, Cambridge, and was successively professor in University College, London, in the University of Virginia, at Woolwich, in the Johns Hopkins University, and at Oxford (Savilian professor, 1883-94); and he published many memoirs, received many medals and honours, was LL.D., D.C.L., F.R.S., and fellow of many foreign academies. He died 15th March 1897. See his *Collected Mathematical Papers* (4 vols., 1904-12).

Sylvester, JOSHUA, was born in 1563. His life was divided betwixt merchandise and poetry, but in neither did he achieve success. Of his original works the human memory retains no trace, save perhaps only in the title of the poem

published about 1620, entitled *Tobacco Battered and the Pipes Shattered by a Volley of Holy Shot thundered from Mount Helicon*; but in virtue of the great though short-lived popularity obtained by his English version of the *Davne Weeks and Works* of Du Bartas he lives in literary history a kind of shadowy life. He led a somewhat wandering existence, and died at Middleburg in Holland in 1618. His works (1641) were reprinted by Grosart in the 'Chertsey Worthies Library' (1878).

Sylvia. See WARBLER.

Sylviculture. See FORESTRY.

Symbiosis (Gr. 'living together'), a biological term introduced by the botanist De Bary to denote an intimate, internal, mutually beneficial partnership between two organisms of different kinds. The case he had in mind was that of lichens, which are actually dual organisms, being composed of Algaoid and Fungoid components living in partnership. The pigmented partner-Alga are able to effect photosynthesis (the utilisation of the carbon dioxide of the atmosphere in the building up of carbohydrates); the partner-Fungi are able to absorb water and salts from their surroundings; the result is a lichen which thrives on rocks and stones, stems and branches, where the problem of subsistence is at its severest. Similarly, as Geddes, Brandt, and others have demonstrated, most Radiolarians of the open sea illustrate symbiosis. The transparent animal cell (or colony of cells) includes symbiotic partner-cells (the so-called 'yellow cells,' referred by most authorities to Alga, by others to Monad Infusorians), which are able in the sunlight to utilise carbon dioxide, to liberate oxygen, and to synthesise carbohydrates, such as starch. Nothing could be better for the symbions than the immediate production of carbon dioxide by their animal partner; nothing could be better for the animal than the liberation of oxygen by the enclosed green symbions. Moreover, the starch made by the symbiotic Alga may be utilised as food by the Radiolarian (see **RADIOLARIA**). The symbiotic Alga are often called technically Zooxanthellae or Zoochlorellae. Symbiotic Alga occur inside some unicellular Protozoa, such as species of Stentor and Vorticella, in some fresh-water sponges (Spongillidae), in the endoderm cells of *Hydra viridis*, in some green sea-anemones, in many Zootharian corals, in many Aleyonarians, in the Planarian worm, *Convoluta*, and in other cases. There is considerable difficulty in deciding whether the green colour of an animal is due to the presence of chlorophyll corpuscles intrinsic to the animal, or to the presence of symbiotic green Alga, which are independent living creatures, sometimes able to fend for themselves.

When an organism simply grows on a plant, like a hydroid on a seaweed, or like one seaweed on another, it is called epiphytic. When an organism simply grows on an animal, like a hydroid on a crab's carapace, or a seaweed on a lobster, it is called epizotic. There is no appreciable partnership in such cases. But when a sea-anemone lives in partnership with a hermit-crab, cloaking or masking it, possibly stinging its enemies, but carried about by it and doubtless sharing crumbs from its repasts, there is an external mutually beneficial partnership, for which the most appropriate term is commensalism. As there are these several words, it is advantageous to restrict symbiosis to *internal* and commensalism to *external* partnerships. Consortism and mutualism are respective synonyms. It is plain enough that these associations must be connected by intergrades. Epizotic or epiphytic organisms may become commensals, and commensals might become

symbions, and symbions are always liable to become parasites (see PARASITIC ANIMALS, PARASITIC PLANTS). In some cases, as in root tubercles, bacteria, which were perhaps parasitic to start with, may become symbiotic (see NITROGEN FIXATION). While it may be desirable to restrict the technical use of the term symbiosis applicable to cases like lichens and Radiolarians and the green Convolute, there is no confusion of thought in saying that the mammalian offspring has an ante-natal symbiosis with its mother.

See COMMENSALISM, EPIPHYTES, LICHENS, PARASITIC ANIMALS; O. Heitwig, *Die Symbiose* (Jena, 1883); Geddes, *Nature*, xxy (1882); Lankester, *Nature*, xxvii. (1882); Brandt, *Archiv. f. Anat. und Physiol.* (1882); and *Mittheilungen Zool. Stat. Neapel*, iv. (1883); and Keesle, *Plant-Animals* (Cambridge, 1910).

Symbol (Gr. *symbolon*, 'a sign') is a word that became significant in connection with a movement conspicuous at the end of the 19th and at the beginning of the 20th century in French literature, especially in poetry. The 'symbolists,' who include such writers as Rimbaud, Verlaine, Mallarmé, Henri de Régnier, and, in Belgium, Maeterlinck and Verhaeren, represent a strong reaction against what had come to be known as realism, in favour of idealism, religious feeling, the sacred, and the antique, and cherish the esoteric, the supernatural, the mystical. They rejoice in the magic charm of music and of melodious words, and seek to make verse and poetry more subtle, intimate, and musical; Wagner was an element of their inspiration, and Debussy associated himself with them, setting many of their poems to music. They even strive to harmonise and blend the functions of the several senses, to associate particular vowels with particular colours; and they count everywhere the metaphysical, transcendental, and mysterious. Many German writers, such as Dehmel, Schöndek, Rilke, Stefan George, and Hugo von Hofmannsthal, were powerfully influenced by the French symbolist school. The Décadents, an offshoot of this movement, drew their inspiration from Baudelaire (see Arthur Symonds, *The Symbolist Movement in Literature*, 2d ed., 1908; also books in French by Kahn, 1902, and Raymond, 1919). Symbolism, however, has also attracted writers so different as Blake and Oscar Wilde, while in art, Pre-Raphaelitism (q.v.) and, to a more limited extent, Post-Impressionism (see PAINTING) can both in their different ways be called symbolistic.

The word symbol is frequently used in a wide and general sense of arbitrary or conventional marks (such as letters of the alphabet, numbers, &c.) which greatly abbreviate methods of scientific expression, as in algebra and mathematics, and especially in chemistry (for chemical symbols, see CHEMISTRY, ATOMIC THEORY). Alchemy and Astrology (q.v.) raised a large crop of symbols; from the latter astronomy has derived not a few. But symbol is now usually almost synonymous with emblem—a concrete and visible figure standing for something moral, intellectual, or religious. A lion is the symbol of courage, a lamb of meekness, &c. Greek and Roman mythology produced a large number of symbols—the trident of Neptune, the peacock of Juno, &c. Early Christian symbolism—originating mainly in a Greek colony in Rome—may be traced in the Catacombs, and an outline of its development has been already sketched in the article CATACOMBS. The greatest number of symbols are those which represent Christ—some mere letters or combinations of letters, as the Monogram (q.v.), composed of A and Ω, of IX and X (for *Christos*; see CROSS), of IHS (initials of *Iesus*). Of another kind is the word ΙΧΘΥΣ, the Greek word for fish, the several letters standing for the initial letters of the Greek words *Ἰησοῦς*

Χριστός Θεοῦ Υἱός Σωτήρ. The symbol of a pictured fish is also used for Christ; and some contend that this symbol, for whatever reason, was in use before the acrostic word was invented or thought of. Then there are pictures of the Good Shepherd, the True Vine, &c. (see also SAINT). So innumerable devices symbolised facts of Christian history, or aspects of Christian truth. In her ritual the Roman Catholic Church has given copious expression to religious symbolism. In architecture also symbolism appears in the cruciform shape of churches, in Orientation (q.v.), &c. In theological language it should also be noted that symbol sometimes means, like the Greek *symbolon*, a creed; hence symbolics is the study of the history and contents of Christian creeds.

See Munter, *Sinnbilder* (1825); Auber, *Histoire et théorie* (1884); Huscenoth, *Emblems of the Saints* (1882); books on Symbolism in Christian Art, by Twining (1886), Hulme (1891), and Clement (1899); Murray Aynsley, *Symbolism of the East and West* (1900); Heath, *Romance of Symbolism* (1909); Samier, *Légende des Symboles* (1911); Schlesinger, *Geschichte der Symbole* (1912); books on Animal and Floral Symbolism by Collins (1913) and Haug (1913) respectively; Silberer, *Problems of Mysticism and Symbolism* (1917).

Syme, JAMES, was born, the son of a Fife lawyer, in Edinburgh, 7th November 1799, and studied at the university. In 1818 he announced a method of making waterproof cloth by means of caoutchouc dissolved in coal-tar naphtha—a process for which a patent was taken out by Macintosh of Glasgow. From 1823 to 1832 he lectured on surgery, and, when refused a surgical appointment in the Edinburgh Infirmary, he established Minto House Hospital at his own expense, where he delivered a clinical course from 1829 to 1833. In 1831 appeared his well-known treatise on *The Excision of Diseased Joints*; and in 1832 his *Principles of Surgery*, which went through many editions, and which established his reputation as a teacher of the first rank. In 1833 he was elected to the chair of Clinical Surgery in the university, and in 1838 he was appointed surgeon in ordinary to the Queen in Scotland. In 1848 he gave up his Edinburgh chair to fill that vacated in London by the death of Liston; but collegiate misunderstandings induced him, after five months, to return to Edinburgh, where he was reappointed to his old chair. His life abounded in controversies. As an operator Syme had no superior; as a teacher he had no equal. His innovations in the practice of his art were characterised by so much ingenuity, controlled by such scientific caution, that they were everywhere adopted. One of the best known of his pupils, Dr John Brown, terms him (*Horæ Subsecivæ*, i.) the 'best and ablest and most beneficent of men,' and the greatest surgeon Scotland ever produced. He further calls his spoken or written style 'the perfection of terse clearness.' Syme was the author of many medical treatises. He died 26th June 1870. See the *Memoir* by Dr Paterson (1874).

Symeon. See DURHAM (SIMEON OF).

Symington, WILLIAM (1763-1831), one of the inventors of steam-navigation. See SHIPBUILDING.

Symmachus, QUINTUS AURELIUS, a distinguished Roman orator, who flourished from 340 till 402 A.D., was educated in Gaul, and became prefect of Rome in 384 under Theodosius the Great, consul in 391. He was sincerely devoted to the old religion, but his purity and nobility of character were worthy of the highest Christian type. His extant writings consist of ten books of Letters, three panegyrics on Valentinian I. and Gratian, and fragments of six senatorial orations. The fragments of the orations were first discovered by Cardinal Mai in a palimpsest, part of which is at

Milan, part at the Vatican, and were successively published in 1815 and 1825.

See Seok's edition in the *Monumenta Germaniae Historica* (vol. vi, 1883), Morin's *Étude* (1847), Dill's *Roman Society* (1898), Glover's *Life and Letters in the 4th Century* (1904).

Symonds, JOHN ADDINGTON, English man of letters, was born at Bristol on 5th October 1840, was educated at Harrow and Balliol College, Oxford, won the Newdigate prize, and was elected a Fellow of Magdalen College in 1862. His first book, *Introduction to the Study of Dante* (1872), was a sort of commentary on the great Italian's poem; it was followed by *Studies of the Greek Poets* (2 vols. 1873-76). But his most notable achievement is *The Renaissance in Italy*, a history of an eventful period written in a highly polished style, with fairly good judgment, and an extensive knowledge of the actors and events of the epoch described. It embraces four parts and a couple of supplementary volumes. *The Age of the Despots* (1875), *The Revival of Learning* (1877), *The Fine Arts* (1877), *Italian Literature* (2 vols. 1881), and *The Catholic Reaction* (2 vols. 1886). *Shakespeare's Predecessors in the English Drama*, published in 1884, contains the results of thoughtful study in English literature. Symonds wrote, besides the books named, two or three volumes of travel sketches in Italy and elsewhere; monographs, *Shelley*, *Sir Philip Sidney*, and *Ben Jonson*; translations of the *Sonnets of Michelangelo and Camerino* (1878), of Benvenuto Cellini's autobiography, and of an interesting collection of students' Latin songs of the 12th century under the title of *Wine, Women, and Song. Medieval Songs in English Verse* (1884); *Life of Michelangelo* (2 vols. 1892); some volumes of verse; and an account of his enforced residence at Davos (1892). He died at Rome, 18th April 1893.

See his *Miscellanies* (1895); *Life* by H. F. Brown (1894), who also edited his *Letters* (1923); *Out of the Past* (1925), by Margaret Symonds (Mrs Vaughan); *Study* by Brooks (1914); and *Bibliography* by Bangston (1925).

Symons, ARTHUR, critic and poet, was born in Wides, of Cornish parentage, in 1865, and educated privately. He is one of the leading exponents of contemporary (especially French) literature, advocating extreme freedom in artistic expression. *Collected Poems* were published in 1901, and *Tragedies* in 1916. His chief work has been *The Symbolist Movement in Literature* (2d ed. 1908). Other volumes of criticism are *Studies in Screen Arts* (1906), *The Romantic Movement in English Poetry* (1909), *Studies in Elizabethan Drama* (1920), and *Baudelaire* (1921). His *Collected Works* (16 vols.) appeared in 1924 et seq.

Symphonic Poem. See PROGRAMME MUSIC.

Symphony, in Music, a form of orchestral composition. The name was originally applied to the purely instrumental portions of works primarily vocal, under it being included overtures to operas and oratorios as well as ritornelli and the introductions to choruses and arias. It received its first restrictive meaning towards the end of the 17th century when, under Lulli and Alessandro Scarlatti, the various instrumental pieces in the operas began to grow in importance: it was then reserved for the opening section or overture, which consisted of a series of contrasted movements without definite rule as to their number or arrangement. Subsequently a plan, attributed to Lulli and known as the 'overture à la manière française,' prescribed three movements, the first and third slow and the

middle one quick and bright. Its place was eventually taken by the 'Italian overture,' in which the three movements were retained but in inverse order, the first and last being quick and the second slow. This form was identical with that of the clavier-sonata, to which, however, the overture long remained inferior in respect of the internal structure of its movements, few composers caring to show themselves at their best in pieces to which talkative audiences paid little heed. As a further result of such inattention it seemed to be forgotten that the overture should fitly foreshadow the work which it preceded: its material, consequently, became distinct and independent, so that it was only natural that the best examples should in course of time find their way into the concert-room, where they met with a more courteous reception. A new outlet being thus provided, original works were soon forthcoming; and with the liberation of the symphony from its operatic surroundings its development as an abstract form of art may be said to have begun. Meanwhile the reinforcement of the ordinary stringed orchestra by certain wind-instruments in the beginning of the 18th century introduced fresh possibilities of expression which reacted on the material of which the movements were composed. In some of Stamitz's symphonies a fourth movement is also found in the shape of a minuet and trio; and with this, the external outline reaches completion. In the works of Emanuel Bach (a son of J. S. Bach), there begins to be a greater freedom of writing between the individual instruments, which up to then tended to be treated in groups, but it was not, however, until 1788, the year in which Mozart wrote his greatest examples, that the symphony attained the rank of an important work of art. In these three works, the E flat, G minor, and C major symphonies, an extraordinary advance is visible both in expression and in richness of instrumental effect. Haydn, though born nearly twenty years before Mozart, wrote his most important symphonies during the eighteen years he survived his younger contemporary. But the symphony was brought to its most perfect stage of development by Beethoven. Not only did he determine the constitution of the symphonic orchestra and expand and elaborate the existing features of the different movements (especially the minuet and trio, which he turned into the scherzo, double the length), but to all this he added in his subject-matter a depth of human emotion such as hitherto had never come within the scope of musical expression. The essential qualities of his music are nobility of thought allied to perfection of detail, and a true balance between material and form. The *Eroica*, C minor, and A major stand as the most perfect examples of the classical symphony, while in the wonderful D minor an elaborate choral setting of one of Schiller's odes is substituted for the usual *finale*. This marks the close of the classical period. In the works of Schubert the 'colour' and 'sentiment' of Romanticism (q.v.) appeared, and in the 19th century two formidable rivals to the symphony (and to the Sonata (q.v.) generally) as the ordinary vehicle of musical expression, rose in the Programme Music (q.v.) of Liszt and Berlioz and in the music drama of Wagner. The symphonies of Mendelssohn, Schumann, Bruckner, and Mahler have, on the whole, not stood the test of time, but those of Brahms are masterpieces of thematic interest and development. Eventually the symphony came to be treated with greater boldness and freedom. Distant modulations, varied choice of keys for the different movements, varied order of the movements, and the 'cycle' scheme of introducing a 'motto' theme in different parts of the work are characteristic, especially of César Franck, Tschai-

kowsky (who was apt to let emotion run riot), and Elgar. Though the 20th century is further characterised by a cult of the *genre* (from Schumann through Grieg to Debussy), and by the elevation of the Russians of the ballet to a separate art form, D. ōik, Saint-Saëns, Glazunov, and Rachmaninov. It more or less worked along classical lines. Sibelius and Scriabin both made the symphony thoroughly individual, and moulded it to suit their own peculiar artistic concepts, while the symphonies of Strauss (*Domestic, Alpine*) and Vaughan Williams (*London, Pastoral*) are conceived rather along the lines of programme music. See articles on the various composers, and the books there cited.

Symplegades. See ARGONAUTS.

Synagogue (Gr. *synagōgē*, 'assembly,' or 'place of assembly,' answering to Heb. *knesseth* or *beth-ha-knesseth*), a Jewish place of worship. The origin of this institution is probably to be traced to the period of the Babylonian captivity, although tradition finds it in the patriarchal times. When, through Ezra's instrumentality, the ancient order of things was restored in Judea, synagogues were established in all the towns for the benefit of those who could not take part oftener than three times a year in the worship of the temple at Jerusalem, and a special ritual of readings and prayers was instituted. From the time of the Maccabees we find them even in all the villages; and Josephus, Philo, the New Testament, the Mishna, and the Talmud constantly allude to them. Common prayer and religious instruction were the purpose for which the people there met. The Sabbaths and feast-days were the principal times on which the faithful assembled in them; there were short services also on Mondays and Thursdays; and the synagogues contributed more than anything else to the people's steadfast adherence to their religion and liberty. At the same time they gradually undermined the priestly and aristocratic element that gathered round the temple, its gorgeous worship and kingly revenues. Erected out of the common funds or free gifts of the community, the synagogue had also to be supported by taxes and donations. All profane doings were strictly prohibited in it; even as to dress the reverence due to the place was enforced as rigidly as possible. It represented in miniature the form of the temple, itself an enlarged type of the tabernacle; the faces of the congregation were turned towards Jerusalem. At the extreme eastern end was the holy ark, containing several copies of the Pentateuch, from which the periodical readings were chanted. Not far from this was suspended the ever-burning lamp. On a raised platform in the middle of the synagogue was the place of the reader or preacher. The women sat separated from the men by a low partition. The affairs of the synagogue were administered by a board of 'ancients' or 'elders,' at whose head stood a chief or principal (*rosh ha-knesseth*; Gr. *archisynagōgos*). This college managed the inner affairs of the synagogue, and had even the power of excommunication. There was an officiating minister (*shelach tzibbur*), whose office it was to recite the prayers aloud. The headle, or *chazzan* (sometimes translated 'minister'), had the general charge of the sacred place and its books and implements. He had to present the scroll to the reader, and assist on other occasions. During the weekdays he had to teach the children of the town or village. This name of *chazzan*, however, at a later period came to designate the officiating minister, and it has retained that meaning until this day. Almoners or deacons collected and distributed the alms. It need hardly be pointed out that the organisation, rites, and modes of worship of the

Christian church in many respects closely resembled, if they were not modelled on, those of the synagogue.

See the articles **Jews, SANHEDRIN, RABBI**; and for the 'Men of the Great Synagogue,' see art. (s.v.) and bibliogr. by H. Engländer in Heb. Union Coll. *Jubilee Volume*, Cincinnati, 1925, pp. 145-170.

For further information in regard to ORIGIN, NAME, HISTORY, and ORGANISATION of the synagogue, see the following articles, to which bibliographies are appended: (1) Itemised references in Hastings, *E.R.E.*, xiii, 581, col. 1; (2) Concise summary by A. R. S. Kennedy (Hastings, *Dict. Bible*, 1909, p. 882); see also *Ency. Brit.*, xxvi, 291; (3) For details, see the longer articles by W. Bacher (*Jew. Ency.*, xi, 619 and Hastings, *Dict. Synaptase. See EMULSIN.

Syncline. See ANTICLINE.

Syncope occurs in music when the accent in a bar is displaced from its normal position, and the rhythm becomes thereby distorted. It is characteristic of jazz and rag-time, but practically all the great classical composers, especially Schumann and Wagner, used syncope to give interest and vitality to their themes.

Syncope. See FAINTING.

Syncretism, usually theological compromise, as between Catholics and Protestants, or more specially between Lutherans and Reformed; see CALIXTUS (GEORG).

Syndicalism, originally a French development of Trade Unionism, is discussed in the article SOCIALISM.

Syndicate. See ASSOCIATIONS, TRUSTS, AND CARTELS.

Synergism, a deviation from the Augustinianism of Luther and the first stage of the Reformation which was regarded as a form of Semi-Pelagianism (see PELAGIUS). Melancthon, who latterly taught expressly that the human will has 'the power of seeking grace,' and that in the work of grace there is co-operation between the Holy Spirit and man's will, was the chief representative of synergism.

Synesius, Bishop of Ptolemais in the Libyan Pentapolis, acted also the various parts of soldier, diplomatist, orator, philosopher, and poet. Born at Cyrene about 375 A.D., he studied at Alexandria under Hypatia (q.v.), whose influence over him proved lifelong. He also studied in Athens; and he returned to the Pentapolis, resolved to spend his life in study, hunting, and the other pursuits of a country gentleman. Appointed a delegate from Cyrene to the Emperor Arcadius at Constantinople, he remained in that city for three years. There, under the veil of a conflict between Osiris and Typhon, who personify Good and Evil, he wrote an allegory describing the contest then going on between Aurelian and the Seythian Gaius; incidentally dealing with the question why God permits evil, and delays so long to interfere. His perilous homeward voyage from Alexandria Synesius described in a long and delightful letter. About 403 he married; and during these years he wrote his treatise *Concerning Dreams*, a half-burlesque essay, *The Praise of Baldness* (he was bald himself), his *Dion*, or on *Self-discipline*, setting forth his ideal of the philosopher, the second part of his book on Providence, several *Hymns*, and a great many letters. This peaceful period was interrupted by war. The Libyan nomads made raids upon the fertile Pentapolis; there were no soldiers at Cyrene, but Synesius raised a troop of volunteers. The helpless governor Cerealius fled; Cyrene was besieged, and Synesius had to organise and direct the defence of the city.

Up to this time Synesius appears before us as a man of letters, steeped in Greek literature and philosophy, and standing quite outside of Christianity. In 409 the people of Ptolemais, fearing the appointment of a corrupt governor, fixed on Synesius as their bishop, who would be at the same time their real political leader and head of the army. Synesius was most unwilling; but at last he yielded, and was consecrated at Alexandria in 410. Doubtless the horrors of war and barbarian invasion forced upon his mind the weakness of Neoplatonism. From this time to his death his life was burdened and weighed down by constant private troubles and public calamities. On his return to Ptolemais he found the new governor Andronicius playing the tyrant, boldly excommunicated him, and secured his recall. As a bishop Synesius acted with great prudence and decision, yet his conscience troubled him, and he felt that he had been presumptuous in undertaking such an office. The Asurians invaded the country, and Synesius had again to spend his nights on the ramparts and direct the defence. His only surviving child died. Synesius was broken with troubles, and both his philosophy and his religion appeared to fail him in his need. The city was relieved, but he fell ill; and about 413 he died. His last letter was written to Hypatia. His last *Hymn*, with its humble prayer for deliverance from indwelling sin, contrasts with the Neoplatonic doctrine of the earlier hymns, the longing of the soul to rise to intellectual communion with God. His letters reveal to us a man open-eyed, of high spirit and awake to every call of duty, sound and healthy in body and mind, passionately fond at the same time of intellectual pursuits and of sport.

See editions by Turnebus (1553), Krabinger (1825-50), Migne (1859), and Flach (1875); studies in French by Druon (1859), in English by Crawford (1901), in Italian by Terzaghi (1907), and in German by Volkmann (1869) and Grützmacher (1913); also the *Letters* translated into English with introduction by Fitzgerald (1926).

Synge, JOHN MILLINGTON (1871-1909), born at Rathfarnham, Co. Dublin, studied music, lived a good deal in Paris, and wrote a series of remarkable plays, illustrating intimately Irish peasant life and character. They include *In the Shadow of the Glen*, *Riders to the Sea*, *The Well of the Saints*, *The Playboy of the Western World*, and *Deirdre of the Sorrows*. Synge was closely associated with Lady Gregory and W. B. Yeats in the foundation of the Abbey Theatre (1904) in Dublin, one of the manifestations of the powerful twentieth-century Irish Literary Movement. His style of writing is at times fantastic and unconventional, but highly picturesque, and musical in its rhythms. See studies by Howe (1912) and Bourgeois (1913).

Synod. See COUNCIL, PRESBYTERIANISM.

Synovial Membrane is a characteristic smooth surface which produces a substance somewhat resembling white of egg and therefore called Synovia, which facilitates the movements of joints, the gliding of a tendon of a muscle, or of the integument over a projection of bone. Its inflamed condition is called *Synovitis*, but this term is extended to inflammation of the joint, or Arthritis. See JOINTS.

Synthesis (Gr. 'a putting together'), in Chemistry, is a term applied, in contrast to Analysis (q.v.), to the building up of compound substances from the elements they contain or from other compounds usually of less complexity than themselves. The term was formerly applied more particularly to the 'artificial' formation by the ordinary processes of the laboratory of substances which were at one time only obtainable as themselves products of the vital processes of plants or animals, or as derivatives from such products. Later the term was especially applied to the building up of complex carbon compounds; the greater part of modern organic chemistry consisting of such synthesis of new compounds of carbon.

Syntheses of new organic compounds are frequently the result of chance discoveries of new reactions, but a very large number of such reactions of more or less general applicability have been studied and classified, so that a new synthesis may be the result of a deliberate attempt to produce a new compound of a definite composition. Similarly the constitution of an important compound occurring in nature, such as, for instance, an alkaloid, is often known with tolerable certainty from the products yielded by it in a series of decompositions, and the information which has been gained from these decompositions indicates the lines upon which an attempt at synthesis may be made with a fair prospect of success. The mode of procedure indicated in the foregoing sentence has resulted in the synthetical or artificial production of numerous substances useful in the arts, in medicine, for domestic purposes, &c. As instances of substances naturally occurring in, or obtainable from, plants or animals, which have also been prepared synthetically, the following may be mentioned: indigo; alizarine, the colouring matter from madder; vaniline, the flavouring principle of the vanilla pods; citric acid, the acid of lemons; urea; uric acid, &c. Amongst the most familiar of synthetically prepared compounds not known as occurring naturally are a large number of the so-called coal-tar colours, saccharine, and many other coal-tar products.

Syntonin (also called Muscle Fibrin), a substance akin to fibrin, which is an important constituent of muscular tissue. See MUSCLE, FIBRIN, PROTEINS.

Syphilis is a highly contagious and inoculable disease, which runs a slow course, usually of many years, after it has gained entrance to the system. The changes which it produces in the tissues are somewhat similar to those found in tuberculosis and leprosy, which are also diseases usually of very gradual development. In addition to showing symptoms for many years, the disease is capable of being transmitted from parents to children (congenital syphilis). The disease is not only passed from one person to another by direct contagion, but the infection can also be transmitted through some vessel or towel which has been recently contaminated. Fortunately, such inanimate objects retain their infectiveness only for a very short time, as the spirochete which causes the disease, when away from a living body, dies in a short time, probably in a few hours. The disease is most commonly transmitted by venereal infection.

This disease has an interesting history. It became extraordinarily prevalent in Europe towards the end of the 15th century, having been first noticed in a widespread form at the siege of Naples by the French troops under Charles VIII. in the years 1494 and 1495. The disease quickly spread in an epidemic form to France and other parts of Europe. By April 1497 the disease had reached Aberdeen, and on 21st April of that year the Town Council of Aberdeen issued a statute dealing with its prevention. This appears to have been the first public notice recognising the nature of the disease. In September 1497 the Town Council of Edinburgh, apparently under the direction of King James IV., issued a stringent regulation commanding all those who were infected to betake themselves to Incheith for isolation treatment, under penalty of being branded and banished. Somewhat similar regulations followed in various towns of England and Scotland.

The New World had been discovered by Columbus in 1492, and there are contemporary records both of the prevalence of this disease in Hispaniola and of its occurrence among the sailors of the navigator. Various bones of American Indians also have been discovered more recently showing traces of this disease. It has, therefore, been contended that the disease was introduced into Europe from the New World by the sailors of Columbus. On the other hand, a disease is described by medieval European writers of the 14th century, such as Guy de Chauliac, showing symptoms very similar to those of syphilis. The probability, therefore, is that a disease of this nature occurred from ancient times in the eastern hemisphere, but that a different variety occurred in the western hemisphere, which spread as an epidemic on its first introduction into Europe.

On its first appearance the disease received various names, such as the *morbus Gallicus*, French disease, Neapolitan disease, and grandgore. The name syphilis was borrowed from that of the chief character in a Latin poem by Jerome Fracastoro, published in 1530. The organism responsible for the disease was found by Schaudinn and Hoffmann in 1905 to be the *Spirochaeta pallida* (*Treponema pallidum*), and an important test for the presence of this disease was afterwards discovered by Wassermann.

The disease may be 'acquired' by contact with persons already suffering from it, or it may be 'inherited' from one or both parents. The general surface of the skin does not seem capable of being penetrated by the organisms of the disease, but the infective material apparently has the power of lodg-

ing in mucous membranes, and various secretions, as well as the blood of persons suffering from the disease, are highly infectious. The disease is frequently spoken of as occurring in three stages—primary, secondary, and tertiary—but this division is purely arbitrary. After an incubation period without symptoms, ranging from a fortnight to six weeks, though most frequently occupying about four weeks, a small ulcer with hard base appears at the site of infection. This is known as a hard chancre or primary sore, and it presents a peculiar character in its resistance to all healing treatment. A short time afterwards the lymphatic glands in the neighbourhood of the sore and, later, those all over the body become enlarged and hard. This condition lasts for several weeks as a rule, and then the sore slowly heals and the glands subside. Before this takes place, or after a period which may be about two months from the date of infection, secondary symptoms appear. These resemble the symptoms of an ordinary fever, including rise of temperature, feverishness, loss of appetite, vague pains through the body, and a faint red rash first seen on the front of the chest. The rash sometimes assumes a more sealy appearance, resembling psoriasis. The spirochetes causing the disease can be found on microscopic examination of a scraping from the primary sore, but the Wassermann test does not give a positive reaction until the secondary stage comes on. Other symptoms which now frequently present themselves are loss of hair, bloodlessness, the appearance of sores in the mouth and throat (mucous patches), headache, and inflammation of the eye (iritis). Painful swellings of the bones are frequently present at this stage, and mental deterioration, due to changes in the blood-vessels of the brain, is not uncommon. The symptoms just mentioned may last for about eighteen months, and thereafter, in the majority of cases which have been recognised and efficiently treated, the symptoms subside and the disease comes to an end. This is recognised by general improvement of health, by the fact that further symptoms do not appear, and by a negative result on carrying out the Wassermann test on the blood.

These secondary symptoms gradually pass into the tertiary stage, or, in untreated cases, tertiary symptoms may develop after the lapse of some months or years. These consist in the development here and there throughout the body of masses of cells, which may spread diffusely along the blood-vessels or may take the form of rounded growths known as 'gummata.' The gummata may appear as hard nodules in the skin or form tumour-like masses in the muscles or various internal organs, or in the brain, where their presence causes very serious symptoms. Those which lie beneath the skin or a mucous membrane may break down and form deep ulcers with characteristic thick, hard, sharply-cut edges. These ulcers, when they heal, leave rounded, brownish scars, whose nature can usually be readily recognised. When a gumma occurs in the central nervous system it gives rise to the symptoms of a tumour, and may cause great destruction. When the cellular formation takes place within or outside of the walls of arteries, as very commonly happens, symptoms result due to defective blood-supply to the organs whose blood-vessels are affected—for example, the brain. A disease of the blood-vessels known as atheroma ultimately results, which in turn is apt to produce aneurysm and premature senility.

Among the latest manifestations of the disease, occurring from five to ten years after the primary onset, are certain disorders in the nervous system, of which locomotor ataxia and general paralysis of the insane are the chief.

The inherited form of the disease may affect a child before birth, frequently leading to miscarriage or to dead-birth of the child. The disease may also show its first symptoms a few weeks after birth with symptoms of inflammation about the nose, mouth, and buttocks of the child, which generally also presents a shrivelled, badly-nourished appearance, with loose, wrinkled skin. The breathing of the child is of a characteristic 'snuffling' type, and the child is very liable to succumb. At a later stage, deafness is a common feature, due to inflammation in the delicate structures of the inner ear. Inflammation of the eye, affecting the cornea (keratitis) or iris (iritis), is apt to appear still later, about the age of twelve or fourteen, causing dimness of vision. Destruction of the bones of the nose, causing sinking and broadening of the bridge, is also a common feature; and the permanent teeth are frequently defective and peg-shaped, the central incisors being notched at the edge.

With regard to the treatment, it is important to remember that any person, whether an adult or an infant, whilst suffering from the earlier stages of this disease forms a serious source of infection to those coming in contact with him. It is, therefore, essential that precautions should be taken both to avoid infection and to effect a cure of the disease as early as possible. The discharge from any sore or abraded surface is especially contagious, and even articles used by the infected person, such as drinking utensils, towels, and clothing, are liable to carry infection. The disease is also highly transmissible to offspring so long as a parent continues to show any manifestation of its presence. With a view to securing thorough treatment, clinics have now been established by most large hospitals and by municipalities.

In the cure of the disease, maintenance of the general health at a high level by suitable dietetic and hygienic measures is of the utmost importance. The drugs which for several centuries have been found to exert a special influence in checking the disease are various salts of mercury, which have been administered by the mouth, by fumigation, byunction in the form of ointment, or by injection into the muscles. Various forms of these are still in common use. In 1910 an organic compound of arsenic known as arsarsan or '606' was introduced by Ehrlich. This was followed a few years later by an improved preparation known as neoarsarsan, possessing less irritating and less toxic properties; and similar preparations under a variety of names such as neoklarsan, novarsenobenzol, novarsenobillon, galyol, &c., are in common use. Still more recently a similar preparation known as tryparsamid, which can with safety be given in much larger doses, has been introduced. All these substances are administered by injection either into a vein or into the substance of a muscle. Another remedy which has been found of considerable use is metallic bismuth in a state of very fine subdivision similarly administered by injection. For the purpose of causing absorption of the products of the disease, such as gummata, thickenings in the blood-vessels, muscles, nervous system, &c., potassium iodide is largely employed in doses of 10 or 20 grains three times daily.

The effect of the various remedies used in treatment is at the present day investigated by performing the Wassermann reaction and various other tests on the blood and, in the case of affections of the nervous system, upon the cerebrospinal fluid. It is usual to carry out these tests some months after a course of treatment has been concluded, and to ascertain that their result is negative before the person can be pronounced completely free of the disease.

Syra (Gr. *Syros*), the most important, though not the largest of the Cyclades (see GREECE). It is about 10 miles long by 5 broad, has an area of 42½ sq. m., and is bare, rocky, and not very fertile. Its prosperity is of quite modern growth. During the War of Independence Syra remained neutral, hence many fugitives of commercial enterprise flocked thither from Chios and other parts of Greece. Pop. of island, 35,000. The capital, *Syra* or *Hermopolis* (pop. 24,000), is situated on a bay on the east side of the island. It rises terrace wise from the shore, is well built, and is the seat of government for the Cyclades, and the seat of a Roman Catholic bishop.

Syracuse, anciently a famous city of Sicily, situated on the south eastern coast of the island, 80 miles SSW. of Messina, was founded by Corinthian settlers in 734 B.C. The colonists occupied the little isle of Ortigia, which stretches south-east from the shore, driving out the Sicels who had already occupied it. The settlement rapidly rose to prosperity, and towards the middle of the 7th century B.C. began to form outposts of its own. Little is known of the early political state of Syracuse; but about 485 the ruling families, probably descendants of the original colonists, were expelled by the lower classes of citizens. Gelon (q.v.), despot of Gela, restored the exiles, and at the same time made himself master of Syracuse. He increased both the population and the power of his new state, and won the highest prestige by a great victory over the Carthaginians at Himera. In his time Aclnadina, a triangular tableland of limestone rock north of Ortigia and on the adjoining mainland, was built upon. This ultimately became the most extensive and populous quarter: it contained the Agora, a temple of Zeus Olympius, the Prytaneum, with a splendid statue of Sappho and fine monuments to Timoleon and the elder Dionysius (q.v.), &c. At a later date, and possibly thus early, there were three other quarters in the city: (1) Tyche, occupying a plateau to the north-west of Aclnadina; (2) Neapolis (New City), stretching along the southern slopes of the plateau, and overlooking the marshes of the Anapus and the Great Harbour, a spacious and well-sheltered bay to the south-west of Ortigia; this islet, however, contained the citadel, which overlooked the docks in the Lesser Harbour on the north; (3) Epipolæ occupied higher ground still further to the west, culminating in the citadel of Euryalus; while the fort of Labdalon, erected by the Athenians during the siege, was slightly to the north-east of Euryalus.

Hiero (q.v.), the brother and successor of Gelon, was celebrated throughout the Greek world as a patron of the fine arts and of men of genius, as Æschylus, Pindar, &c. In 466 B.C. the democracy again got the upper hand—Thrasylbus, Hiero's brother and successor, a 'tyrant' of the baser sort, being expelled; and for sixty years a free and democratic government was enjoyed, under which Syracuse flourished more than it had ever done. During this period occurred the great struggle with Athens (415-414 B.C.), and the celebrated siege by the Athenian armament, a contest in which the Sicilian city came off victorious (see NICIAS). Nine years later Dionysius (q.v.) restored the 'tyranny' of Gelon, and during a reign of nearly forty years greatly increased the strength and importance of the city (see SICILY). It was he who constructed the docks in the Greater and Lesser Harbours, and surrounded the city with fortifications. His fierce war with Carthage (397 B.C.) raised the renown of Syracuse still higher. The reigns of the younger Dionysius (q.v.) and of Dion, the friend of Plato, were unsettled; but after the restoration of public liberty by Timoleon (343 B.C.) a brief season of

tranquillity ensued. In 317 B.C., twenty years after the death of the noble Timoleon, Agathocles, a rude soldier of fortune, once more restored the despotic form of government, which continued, with scarcely an interruption, through the reign (fifty-four years) of the enlightened Hiero II., the friend and ally of Rome, down to the conquest of the city by the Romans after a siege of two years, in which Archimedes perished (212 B.C.). This event was occasioned during the Hannibalic war by Hieronymus, a rash and vain young man, abandoning the prudent policy of his grandfather, Hiero (q.v.), breaking the alliance with Rome, and joining his and their foes, the Carthaginians. Under the Romans Syracuse slowly declined, though with its handsome public buildings and its artistic and intellectual culture, it always continued to be the first city of Sicily. It was captured, pillaged, and burned by the Saracens in 878 A.D., and after that sank into complete decay. For ancient Syracuse, see Freeman's *History of Sicily*.

The modern city (*Siracusa*) was until lately confined to the original limits, Ortygia, where the streets, which are defended by walls and a citadel, are, with few exceptions, narrow. Here are the baroque cathedral (built into the ancient temple of Minerva), an archaic Doric temple of Apollo, a very important museum of prehistoric and classical antiquities, numerous churches, monasteries, and nunneries, the ancient fountain of Arethusa (its waters mingled with sea-water since the earthquake of 1170), and some interesting mediæval palaces. A new quarter is now growing up on the mainland, between the railway station and the bridge leading to Ortygia. Here are scanty remains of the Agora, later the Forum of Roman days, and of the gymnasium. To the NE. in the suburb of Santa Lucia, below the Norman church of that name, are large catacombs, (2d-3d cent. A.D.), and on the shore are remains of the ancient arsenal. To the N. are the more recent catacombs (4th-6th cent.) of S. Giovanni (the catacombs of Syracuse are only second to those of Rome), and the huge quarry known as the Latomia dei Cappuccini, one of those in which the Athenian prisoners languished.

Further west, in the ancient Neapolis, are the large Roman amphitheatre, cut in the rock except on the south (460 x 390 feet); the altar erected by Hiero II. to celebrate the fall of Thersibolus; the Latomia del Paradiso (with the celebrated grotto known as the Ear of Dionysius, which has as a fact extraordinary acoustic qualities); and the Greek theatre, the auditorium of which, 440 feet in diameter, is one of the largest in the Greek world. It, too, is almost entirely hewn in the rock. Less is left of the stage, but the whole has been the subject of a monograph (Rizzo, *Il Teatro Greco di Siracusa*), and the surroundings and the splendid view have led to the frequent use of this theatre for performances of Greek tragedies in recent years. Above it is a street of tombs, and hereabouts was an important cemetery of the ancient city. From this point the walls of Dionysius can be followed all round the edge of the plateau of Epipolæ as far as the great fortress of Euryalus, the key of the whole system recently excavated. It is protected by three large ditches on the west, connected by passages with a massive keep built of hewn stone, which joins the walls of Epipolæ on the east. These walls can also be traced along the north and east (sea) edges of the plateau. On the opposite side of the Great Harbour to Ortygia is the Temple of Zeus Olympius, of which only two columns remain, and not far off the famous spring of Cyane, where the Syrian papyrus still grows. Still further to the

south is the peninsula of Pleumyrrion, between which and Ortygia was the line of ships by which the Syracens closed the harbour against the attempts of the Athenians to force their way out. The people manufacture chemicals and pottery, and trade in fruits, olive-oil, wine (exports), wheat, timber, and petroleum (imports) Pop. (1921) 49,662.

See B. Lupus, *Topographie von Syrakus* (Strasbourg, 1887); E. Mancieri, *Siracusa* (Bergamo, 1909).

Syracuse, an important city of central New York, seat of Onondaga county, lies in the beautiful Onondaga valley, stretching along Onondaga Creek to the head of the lake of the same name. It is on the Erie Canal, and is a terminus of the Oswego Canal; by rail it is 148 miles E. of Buffalo and 147 W. of Albany. Syracuse is the seat of a Methodist Episcopal university (1870), with over 6000 students. It carries on an extensive shipping business, but the production of salt, formerly its chief product, has now declined. There are manufactures of automobiles, boilers and engines, furniture, clothing, shoes, canned goods, china, typewriters, silverware, and agricultural implements. The salt-springs were visited by French missionaries as early as 1654, and began to be worked by white men in 1789; the city was incorporated in 1847. Pop. (1880) 51,792; (1900) 108,374; (1920) 182,003.

Syr-Daria. See JAXARTES.

Syria, a country of western Asia, embracing, in a wide sense, the regions that lie between the Levant and the Euphrates from Mount Taurus in the north to the southern border of Palestine, or even to the peninsula of Sinai. The eastern boundaries south of the Euphrates are not clearly defined or marked off from the wide expanse of the Arabian desert. The physical conformation of Syria is throughout simple and uniform. A range of mountains, split in the north into two parallel chains—Libanus and Anti Libanus—fronfs the Mediterranean, ranging in height from 6000 feet in the north up to 10,000 feet in the central parts, but falling again in the south to 3500 feet. Behind these mountains lies a tableland, that gradually falls away eastwards to the desert. The separate districts of Syria have been already described in geographical detail in the articles LEBANON, PALESTINE, PHENICIA, BASHAN, HAURAN, DEAD SEA, JORDAN. The prevailing winds being westerly, the slopes of the mountains next the Mediterranean and the valleys ensconced among them, together with the immediate seaboard, get a tolerably plentiful supply of moisture during the rainy half of the year (October to May); snow even falls on the highest summits of the mountain-ranges. The climate on the plateau is generally dry, and in certain localities hot. The valley of the Jordan is remarkably hot. The soil is in many parts possessed of good fertility, and in ancient times, when irrigation was more extensively practised, yielded a much greater return than it does at the present time. Damascus is noted for its gardens and orchards. Hauran produces excellent wheat; Northern Syria, the olive. The vine grows in nearly all parts of the country. Fruit (oranges, figs, &c.) is cultivated on the coast plains. Sheep and goats are the most important of the domestic animals. The principal exports are cereals, tobacco, wine, fruits, liquorice, sesame, silk and cotton stuffs, and copper and brass goods. Among the chief imports are Manchester goods, woollen clothing, timber, hides, sacking, iron and copper goods, petroleum, and coal.

There has been a steady improvement in the roads of Syria, and there are now excellent motor roads along the coast, all over the Lebanon, from

Beirut to Damascus and around the latter city. There is a railway from Beirut to Damascus which is linked up at Rayak by a line running through Baalbek, Homs, Hama, and Aleppo, with the Turkish Baghdad Railway. South of Damascus the Hejaz railway runs, in a semi-ruined condition, to Medina, and at Daraa gives off a branch which runs westward through the valley of the Yarmuk to link up with the Palestine railways. A short line also runs between the port of Tripoli and Homs.

Since the Great War the term Syria has more than ever come to be confined to northern Syria, leaving Palestine, as has been the case in previous historic periods, as a distinct unit.

Under the French mandate Syria was originally divided into four federated autonomous states. (1) The Great Lebanon (*État du Grand Liban*), a state which includes not only the former semi-independent Lebanon (q.v.), but also Beirut (the capital), the other coastal towns—Tyre, Sidon, Juchel, and Tripoli—and most of the region *el Bqûia* (Cele-Syria), with Baalbek (Heliopolis), famous for its wonderful ruins. The population of the Grand Lebanon now numbers over 700,000. (2) The state of the Alewites or, as we have been accustomed to call them, the Ansariëh—a sect of nonorthodox Moslems—whose capital is at Latikeyeh. (3) Damascus, including the Sanjaks of Homs, Hama, and the Hauron; and (4) Aleppo, with Alexandretta and Deir ez Zor. More recently the last two states have been united; their districts are now disorganised and the final arrangement has not been settled.

The population of French Syria is about 3,000,000. The larger proportion are orthodox Moslems—Arabs, with a few thousand Circassians; but there are Druzes in the Lebanon and the Jebel Druze (Hauron), Ansariëh and some scattered Shiites in the north, and many Christians—chiefly Maronites, Roman Catholics, Greek Orthodox, and Armenians—in the Lebanon, and in all the larger cities. The political administration of a people so varied in interests and so mutually antagonistic in their tenaciously held beliefs is a task of extraordinary difficulty.

The earliest historical records that treat of Syria are those that relate the histories of the Hittites (q.v.), the Phœnicians (q.v.), and the Hebrews (see JEWS). The first named were for several centuries supreme in northern Syria, and at times stretched their authority southwards as far as the hills of southern Palestine. Yet they had most formidable rivals on both sides of them in Assyria and Egypt, from both of which countries their subjects derived no small share of their skill in manufacturing industry, and in the arts and manners of life. The other two peoples mentioned occupied the most prominent place in southern Syria. Nevertheless at different periods we read of flourishing Aramæan (Semitic) principalities, such as Damascus, Hamath, Zobah, and similar petty states. These, as well as most of northern Syria, were conquered during the 8th century B.C. by the kings of Assyria; the Jewish kingdoms experienced the same fate at the hands of the Babylonian kings in the 7th and 6th centuries. As previous to the 9th century B.C. Syria had been the battle-ground of the Egyptian and Hittite armies, so after that period it was, as a province of Assyria (Babylonia), involved in the struggle between that great empire and Egypt. (The Greeks first knew this region as a province of Assyria; hence the contracted name Syria.) Towards the end of the 6th century B.C. Syria fell under the dominion of the Persian empire; and two centuries later it was conquered by Alexander of Macedon. When his empire broke to pieces the Seleucidæ (q.v.) made Antioch the capital

of their empire of Syria. From the Seleucidæ it passed, through the hands of Tigranes of Armenia, to the Romans, for whom it was won by Pompey in 64 B.C. Under these new masters the country flourished and became celebrated for its thriving industries, its commercial prosperity, and its architectural magnificence (see BAALBEK, PALMYRA; also NABATEANS). On the division of the Roman world Syria became part of the Byzantine empire, and of it remained a province until its conquest by the Mohammedan Arabs in 636. It still continued to be prosperous under the Arabs and their successors the Egyptian sovereigns, in spite of the unsettled period of the Crusades (q.v.). The first severe blow it suffered came from the Mongols in 1260, and its ruin was continued when in 1516 it passed from the Egyptians to the Ottoman Turks. In 1918 British forces, aided by Arab detachments under Colonel Lawrence, and a few French troops, cleared the Turks out of Damascus and Beirut, and pursued them northward until they sued for peace after the capture of Aleppo. The land so liberated was bestowed by mandate of the Supreme Council of the Allies upon the French. At first the cities of Damascus and Aleppo—with the country between them—was assigned as an independent Arab district under the Emir Feisal (now King of Irak), but after the Arabs attempted to break away from all control by the French, the district was occupied by the French troops and the emir was expelled (1920). Since then the French have been endeavouring to cope with the administration of the whole of Syria through a High Commissioner resident in Beirut, but so far with indifferent success. A rebellion among the Druzes, originating in want of understanding and tact on the part of the French governor, spread to the disgruntled Arabs of Damascus and other inland cities of Syria. The French have been compelled to employ considerable military forces, but the methods of violence exhibited in the bombardments of Damascus, and its environs have turned many earlier loyal friends of the French into active enemies. In the Lebanon, though there has been no active fighting, considerable dissatisfaction has been expressed by the Maronites on the one hand and the Moslems on the other at the extension of the autonomous Lebanon to include so many incompatible elements.

See Burton and Drake, *Unexplored Syria* (2 vols. Lond., 1872); Lady Burton, *Inner Life of Syria* (1875); Von Sudenhorst, *Syrien und seine Bedeutung für den Welt-handel* (Vienna, 1873); Lortet, *La Syrie d'aujourd'hui* (Paris, 1884); Baedeker's *Palestine and Syria* (by Professor A. Soein); C. R. Conder, *Heth and Moab* (1883); De Vogüé, *Syrie Centrale; Archéologie Civile et Religieuse du Ier au VIIe Siècle* (Paris, 1865-77); Leonard Stein, *Syria* (1926); *Syrie. Revue d'art oriental et d'archéologie*; and books quoted under the various articles cited above.

The Church of the Syrian Rite was that portion of the oriental church which had its seat in Syria, and which was anciently comprehended in the patriarchate of Antioch and (after that of Jerusalem obtained a distinct jurisdiction) partly in the patriarchate of Jerusalem. The Syrian Church of the early centuries was exceedingly flourishing; before the end of the 4th century it numbered 119 distinct sees, with a Christian population of several millions. The first blow to its prosperity was the fatal division which arose from the controversies on the incarnation (see EUTYCHES; GREEK CHURCH, Vol. V., p. 398). The Eutychian heresy, in one or other of its forms, obtained wide extension in Syria; the Moslem conquest accelerated the ruin thus begun; and from the 7th century downwards this once flourishing church declined into a weak and spiritless

community, whose chief seat was in the mountains, and whose best security from oppression lay in the belief on the part of the conquerors of its utterly fallen and contemptible condition. See also NES-TORIUS; THOMAS (CHRISTIANS OF ST); LITURGY; SEMITES; BIBLE; O. H. Parry, *Six Months in a Syrian Monastery* (1895).

Syringa, a name properly belonging to a genus of Oleaceæ, for which see LILAC, is often improperly applied to *Philadelphus coronarius* and other species of *Philadelphus*, a genus of Saxifragaceæ. *Philadelphus* is a small genus of opposite-leaved shrubs, natives of the north temperate regions of both hemispheres. *P. coronarius*, the mock orange, probably of Japanese origin, has strongly scented yellowish-white flowers.

Syrmia (Serb. *Srijem*, Mag. *Szerém*), the eastern-most corner of Slavonia, between the Drava and Danube and the Sava.

Syrtis, the ancient name of two gulfs of the Mediterranean Sea, on the north coast of Africa. The Syrtis Major, now called the Gulf of Sidra, lies between Tripoli and the tableland of Barca, and forms the most southerly part of the Mediterranean. The Syrtis Minor, now called the Gulf of Gabes, lies between Tunis and Tripoli. The shores of both are inhospitable, and abound in quicksands.

Syrup (Fr. *sirop*, Span. *jorope*, Arab. *sharâb*, 'a beverage,' 'wine,' 'syrup'; *shrub* is a doublet; and *sherbet*, Arab. *sharbat*, is from the same root), in its simplest meaning, a saturated solution of sugar boiled to prevent fermentation; but it also means the juice of fruits saturated with sugar and many flavoured liquids, treated in the same way. In general the finest refined sugar is used; and every effort is made to get the syrup very clear and free from all feculent matter. Syrups of fruits are much used on the Continent to mingle with water for drink, and are very wholesome. The 'golden syrup' of the grocer is the uncrystallisable part finally separated in the manufacture from crystallised sugar (see SUGAR). Medicinal syrups contain with the sugary element some therapeutic agent. Parrish's Syrup contains the phosphate of iron with the phosphates of lime, potash, and soda, dissolved in dilute phosphoric acid, sugar being added. Easton's Syrup has in it phosphate of iron, with the phosphates of quinine and strychnine. There are syrups of the hypophosphites, and many others.

Syrus, EPHRAËM. See EPHRAËM SYRUS.

Syrus, PUBLIUS or PUBLILIUS, a Roman writer of mimes who flourished about 43 B.C., and was most probably a Syrian slave brought to Rome in early youth, educated, and freed by some indulgent master. After Laberius he reigned supreme on the stage, and his mimes, being as full of shrewd epigrammatic wit as broad humour, did not altogether perish with him. About two hundred apophthegms are still extant, under the title *Publii Syri Mimi Sententiae*. One of these supplied the motto for the *Edinburgh Review*, although Sydney Smith admits that none of the young collaborators knew anything further of its author: 'Judex damnatur cum nocens absoluitur.'

Syzran, a town of Central Russia, on the river Syzran, near its confluence with the Volga, and 90 miles S. of Simbirsk (Ulianovsk). Laid out in 1685, it has tanneries and noted market-gardens, and a large trade in grain, timber, salt, and manufactured goods. Pop. 50,000.

Szyzygy (Gr. *szyzygia*), a term used indifferently either for the Conjunction (q.v.) or opposition of the moon.

Szabadka. See SUBOTICA.

Szarvas, a town of Hungary, on the river Körös, 80 miles SE. of Budapest. A good breed of horses is cultivated here. Pop. 25,000, mostly Slovaks, who, however, speak Magyar.

Szatmar-Nemeti, a town of Rumania, on the Szamos, 68 miles by rail NE. of Debreczin, with a Roman Catholic cathedral, and a trade in wine. Pop. 35,000.

Sze-chwan, a large province of China, 220,000 sq. m. in area, is situated in the west, having Tibet on the north-west and Yunnan on the south-west. It is traversed and watered by the Yang tsze-Kiang and its affluents, is hilly throughout, mountainous in the west, and rich in natural products, including coal, iron, and other minerals. Silk, salt, sugar, medicines, tobacco, hides, musk, rhubarb, and white wax (produced by an insect) are largely exported; and European cottons and woollens are imported, while opium used to be a special crop. The capital is Cheng tu (q.v.), the chief commercial town Chung-king (opened to foreign trade in 1891) and Ichang (q.v.). Wanhien was opened in 1917. The province was thrown into much confusion by the revolutionary movement of 1911, and by the political disturbances after the Great War. Pop. variously estimated at 23,000,000 to 50,000,000.

Szegedin, or SZEGED, the second town of Hungary, stands at the confluence of the Maros with the Theiss, 118 miles by rail SE. of Budapest. This town was almost completely destroyed by a terrible flood in March 1879, and since then it has been rebuilt, and now possesses very handsome public buildings, including a town-house, post-office, law-courts, theatre, barracks, &c., and is protected against inundations by a double ring of embankments. The Theiss is spanned by a couple of railway bridges and a fine suspension bridge (1940 feet long), designed by Eiffel. Szegedin is the commercial centre of the Alföld, the vast Hungarian plain, manufactures soap, spirits, matches, soda, tobacco, coarse cloth, &c., and carries on an extensive river trade in wine, corn, and wool. A speciality of the place is *paprika* (see CAPSICUM). From 1526 to 1686 it was occupied by the Turks. Close by Haynam defeated the Hungarians on 3d August 1849. Pop. (1880) 73,675; (1920) 119,109.

Szeklers. See TRANSYLVANIA.

Szenta. See ZENTA.

Szentes, a town of Hungary, 30 miles N. of Szegedin near the left bank of the Theiss. Pop. 32,000, chiefly engaged in wine-culture.

Szolnok, a town of Hungary, on the Theiss, 66 miles by rail E. by S. of Budapest, with a lively trade in tobacco, timber, and salt. Pop. 32,500.

T

the twentieth letter of our alphabet, descends from the twenty-second and last letter of the ancient Semitic alphabet. In the 9th century B.C. the letter was written **X**; its

Semitic name, *tāw*, adopted by the Greeks as *tau*, coincides with the Hebrew word for a

mark or sign; the related verb *tiwā* means to make marks, scribble. The cross **X** is perhaps the most natural mark to use for distinguishing one out of a number of similar objects, and it may have been called *tāw* before the invention of the alphabet. On the other hand, the word in the sense of 'mark' may be merely a use of the name of the letter, which in that case may have been a meaningless syllable formed on the analogy of *wān* (see the article F) to indicate the *t* sound. An early Semitic form of the letter was **†**; the Hebrew **ת** has lost all resemblance to the original shape.

In the oldest Greek inscriptions the letter already appears in the form **Τ**, which was adopted unchanged by the Romans. In Roman cursive the stem was rounded, producing the form **τ**, which was variously modified in mediæval script; an ornamental variety of it survives in the English black-letter capital. In many mediæval MSS. the minuscule *t* is almost or entirely indistinguishable from *c*. To make the distinction clearer, the upright part of the letter was continued above the cross-bar, yielding the form which developed into the modern printed *t*.

The normal sound of the letter has always been some variety of the voiceless stopped point consonant, in the utterance of which the breath escapes from a stoppage produced by contact of the tongue with the gums or the palate. In English the point of contact is farther back than in other European languages. In late Hebrew and Aramaic this sound when preceded by a vowel became open, like the English *th* in *thin*. In several modern languages the letter has in certain words an abnormal pronunciation, the spelling being etymological. Thus *t* is pronounced as *s* in the French *aristocratie*, &c., as *ts* in the German *Nation*, &c., as *sh* in the English *nation*.

The Romans used **TH** in Greek proper names and in words adopted from Greek to represent the sound of the letter Θ, *thēta*, which was an aspirated *t* (= *t* + *h*). In late Latin *th* came to be pronounced as a simple *t*. Hence in French the *th* retained in certain classical and biblical names and in words derived from Greek is pronounced *t*; in the Middle Ages *th* was often written for *t* quite without reason. In English *th* is pronounced as *t* in *Thomas* and its derivatives Thom(p)son, Thoms, and in certain names in which the *h* has no etymological justification, as Thames, Anthony. In German, *th* (pronounced *t*) was formerly written in many

words, both initially as in *theuer*, *thun*, *That*, and finally and medially as in *Rath*, *Hemath*, *worthen*; but recent reforms substitute *t* in these words, though *th* remains in Greek derivatives. In modern Italian and Spanish orthography *th* is never used.

In the earliest Old English MSS. *th* was written for the voiceless interdental spirant, a sound which did not exist in Latin. The choice of this symbol may have been a result of the study of Greek, the letter *thēta* having in late Greek come to have the sound of the English spirant. Subsequently this use of *th* was discontinued (probably because the digraph was differently pronounced in Latin), and the character þ (called *thorn*) was imported from the Runic alphabet. This letter came to be used for the interdental spirant whether voiced (as in *this*) or voiceless (as in *thou*); and the letter ð (see the article D) was similarly used with both values. The ð became obsolete in the 13th century, but the 'thorn,' latterly identical in form with *y*, continued in occasional use till after the introduction of printing (as in the well-known *yf* for *th*). In the 13th century some scribes already occasionally substituted *th* for þ; and in the end the digraph became the regular symbol for the two sounds (as in *this*, *thin*). In Welsh *th* is used for the voiceless spirant, as in *thin*.

The dotted **ṭ** is used in Irish to express an *h* sound derived from an original *t*. In transliterated Irish and in Scottish Gaelic this sound is written *th*.

The Roman name of the letter, *tē*, is preserved in all the modern languages written in the Roman character.

Taal, **AFRIKAANS**, or **CAPE DUTCH**. See **SOUTH AFRICA** (*Languages*), **BOERS**.

Tabard (most probably, like *tapert*, ultimately from Lat. *tapet*, 'hangings'), a heavy outer coat of rough cloth once worn by poor people; also a loose cloak without sleeves worn by knights over their armour, usually embroidered with their arms—Chaucer's *cote-armour*. The latter use survives in the distinctive coat with short sleeves, worn by heralds and pursuivants, emblazoned with the royal arms.

Tābari, a Moslem historian. See **ARABIAN LANGUAGE**.

Tabasco, a state in the south of Mexico, consisting largely of a flat plain, which is sometimes partly inundated by the Gulf of Mexico. Sugar, coffee, cocoa, fruits, and rice are cultivated, and there are petroleum mines. Area 10,374 sq. m.; pop. (1921) 178,389.

Tabasheer, a substance sometimes found in the cavities or tubular parts of the stems of bamboos and other large grasses. It consists chiefly of silica with a little lime and vegetable matter, or sometimes of silica and potash, in the proportions of about 70 parts of silica and 30 of potash. It appears to be formed by extravasation of the juices of the plant, in consequence of some diseased condition of the nodes or joints. It is in high repute among the Hindus as a tonic, and is prepared by

imperfect calcination and trituration. The powder is often chewed with betel in order to renovate the constitution. There are several varieties of tabasheer, one of which, of very rare occurrence, is extremely beautiful, of a delicate azure colour by reflected light, and of a faint yellowish hue by transmitted light, easily crushed between the fingers, and of 'an aerial and unsubstantial texture, which we look for in vain in any other solid.' Other varieties are yellowish, white, and much like some varieties of opal. Tabasheer is very porous, and absorbs water and oil very rapidly; effervescence taking place when it is plunged in water. By absorption of oil the opaque variety becomes transparent. When the greater part of the oil is expelled by heat the structure of the tabasheer becomes apparent; it is beautifully veined, the veins being sometimes parallel and sometimes curved.

Tabernacle (Lat. *tabernaculum*, 'tent'), the portable tent in which the Ark of the Covenant (q.v.) was conveyed, and as such the sanctuary of Israel. It seems (1 Sam. iii. 3) to have been superseded by a more permanent building at Shiloh before David's time. See TEMPLE.—In Roman Catholic churches the name is given to the receptacle in which the consecrated elements of the Eucharist are retained. It is commonly a small structure of marble, metal, or wood, placed over the high altar, and appropriated exclusively to the reservation of the Eucharist, no other object whatever being allowed to be kept in it. See PYX, and the illustration at Altar; and for the Feast of Tabernacles, see FESTIVALS.

Tabes Dorsalis. See LOCOMOTOR ATAXIA.

Tabes Mesenterica. See MESENTERY, and TUBERCLE.

Tablature, a method of musical notation, principally employed in the 15th and 16th centuries for the lute, but also used occasionally for other instruments. In tablature the lines of the stave indicate the strings on the instrument, the upper line representing the first string, the second line the second string, &c. The notes are expressed either by Arabic numerals or small letters, which denote the semitones of the chromatic scale, or the frets at which the fingers ought to be placed to stop the strings—*a* indicating the open string, *b* the first fret, *c* the second fret, and so on. The duration of the sounds is expressed by minims, crotchets, quavers, &c. placed above the stave, over the letter or letters which they are meant to affect, and each of the musical notes is held to apply to the letters immediately following, making them of the same length as the first, until some new note occurs. The method of tuning the lute must be ascertained before any particular tablature can be deciphered, as the pitch of the notes produced by the use of the frets will depend upon that of the open strings. One of the best-known tablatures is that given in the famous Skene manuscript in the Scottish National Library, Edinburgh, written at various times up to 1635.

Tableaux Vivants ('living pictures'), representations of works of painting and sculpture, or of scenes from history or fiction, by living persons. They are said to have been invented by Madame de Genlis, when she had charge of the education of the children of the Duke of Orleans. They were long common in theatres.

Tablelands, or PLATEAUS, are extensive elevated regions with a plain-like or undulating surface. They may be bordered by steep declivities falling more or less suddenly from the level of the plateaus to the sea or the adjacent low grounds; or they may slope down imperceptibly and thus

gradually merge with the lowlands. The tableland of the Spanish peninsula is a good example of a plateau that rises abruptly from the sea. The 'Great Plain' lying east of the Rocky Mountains, on the other hand, is a plateau that sinks gradually from a height of 6000 feet down to the low prairie lands of the Missouri. Some high tablelands are surrounded by lofty mountains, such as those of Quito, Titicaca, and Uspallata in the Andes, and that of the Pamir in Asia; while others constitute elevated platforms upon which mountain-ranges stand. Two types of tableland are recognised: (*a*) plateaus of accumulation and (*b*) plateaus of denudation. The former are built up of horizontal or approximately horizontal strata, while the latter are composed of disturbed strata which have been planed down to one general level (see MOUNTAINS). The chief tablelands are in Europe, central Spain; in America, Oregon, the great salt plain of Utah, the north and centre of Brazil; in Africa, the interior of Barbary; while in Asia almost the whole of the south and centre of the continent consists of plateaus, which rise terrace above terrace till they culminate in that of Tibet. Of the Asiatic plateaus the principal are those of Asia Minor (3280 feet above sea-level), Armenia (7000), Persia or Iran (3000), Mysore (4000 to 5000), Deccan (1500 to 2000), Tibet (12,000 to 17,000), and Chinese Tartary (3000 to 4300).

Table Mountain. See CAPETOWN.

Table-turning, a phenomenon attributed, with other more occult movements of furniture, to the agency of spirits (see SPIRITUALISM), but practised also in America and Britain from about 1850 as a kind of social pastime; the motion of a table under the finger-tips of a closed circle of 'believers' standing round the edge of the table being referred to a mysterious or occult origin, and not, as by the more sceptical, to the collective but involuntary muscular action of the circle of friends.

Taboga. See PANAMA.

Taboo. See TABU.

Tabor, a dome-shaped, oak-clad hill of northern Palestine, 7 miles E. of Nazareth, rising solitarily in the north-eastern part of the plain of Esdraelon to a height of about 1000 feet. In the 2d century it was regarded as the Mount of Transfiguration, and the ruins of a crusading church on the summit commemorate this event. Tabor is not named in the New Testament.

Tabor, a small drum like a timbrel or tambourine without jingles, usually played with one stick and in combination with a life.

Taborites. See HUSS.

Tabriz, a great and ancient city of Persia, capital of the province of Azerbaijan, 40 miles E. of Lake Urumiah, and on the Aji, which flows south-west into that lake. The interesting ruin, Kabúd Masjid, or 'blue mosque' (dating from 1450), is in part covered with blue tiles beautifully arabesqued. The citadel is a spacious edifice of burned brick, the walls of which have been cracked in many places by earthquakes. Tabriz is the seat of a varied industry, in which leather, silk, and gold and silversmith's work alone are notable, and is still a vast market and distributing centre. The chief imports are cotton fabrics, sugar, woollen cloth, and wines and spirits. The chief exports are drugs and spices, dried fruits, shawls, carpets, and raw silk. By the opening of the Transcaucasian railway between the Black Sea and the Caspian, with a branch line extended to Tabriz, the overland trade with Trebizond has rather been replaced by trade with Russia. Commerce, however, has been fluctuating, owing to 20th-century political disturbances in Russia, Armenia, and Persia.

The Anglo-Indian telegraph line passes through the city. There has been much debate about the identification of the city with an ancient *Tauris*; it was reputed to have been refounded in 791 by one of the wives of Harūn-al-Rashid. In 858, 1041, 1721, and 1854 it was devastated by earthquakes, and it has been besieged, taken by Turks, Turcomans, and Persians in succession. During the Great War it was occupied first by Turks and then by Russians. Pop. about 200,000.

Tabu, a word adopted into European languages from a Polynesian dialect in which it originally meant 'strongly marked' and was used to designate sanctity and allied notions and also the ritual prohibitions connected with things deemed sacred or unclean. In the Polynesian sense of the term the quality inherent in the person or thing tabued is communicable to the violator of the tabu, which thus spreads wider and wider. At the present day tabu is often used where there is no idea of contagious sanctity, to indicate the ritual character of a prohibition; common usage has further extended the meaning to embrace prohibitions of whatever sort.

In civilised communities there is a distinction between things sacred and things profane; but the rôle of the former is not a large one in the life of the ordinary man; he is never hampered in business or social relations by anything resulting from the existence of the non-profane. With uncivilised peoples the case is wholly different; their lives are largely regulated by considerations connected with religion, and one of the most important elements is the complex of prohibitions called tabu. It must be remembered that there is no moral quality connected with the idea of sanctity, as is clear from the fact that sanctity and uncleanness (ritual impurity) are virtually indistinguishable; the Hebrew word commonly translated 'accursed' also means 'devoted,' and the object designated by the latter term is 'most holy'; the Latin word *sacer* has the same ambiguity in meaning, for a man who removed a landmark was so termed, and he was an outlaw who might be killed by any one.

(1) Tabu in its strict sense depends upon the sacredness inherent in persons or things, either as a result of being charged with supernatural power, or as being associated with gods or spirits; and, secondly, upon the sacredness derived from things naturally tabu which infects the violator of the ritual prohibition with their own sacredness. A person strongly charged with *mana* (supernatural power) may impose a tabu and thus charge with his own power anything exposed to danger. Tabu can therefore be classified as natural or direct, and communicated. It is possible for both kinds to be concentrated on one object.

Among things naturally tabu are chiefs, priests, warriors, burial grounds, women after childbirth, &c.; the reason is twofold; the tabued person may be in some way endangered by contact with the profane world; but on the other hand it is just as probable that he will endanger the profane world if he comes in contact with it. One result of this may be seen in gradations of rank, which result in the separation of king or priest from the commons or laity by a protective wall of functionaries whose *mana* is stronger than that of the common man and therefore capable of fortifying them against the dangerous contact with the man of powerful *mana*.

The violation of a tabu may bring with it its own punishment; when Uzzah put out his hand to steady the ark he was struck dead. On the other hand the *mana* of the transgressor may be so powerful that he escapes the direct chastisement caused by the supernatural impersonal force or by the god; but in this case his less well-equipped fellows may

suffer; hence there are social sanctions for a breach to tabu, so that vengeance may fall upon the guilty and the innocent may be spared. The community may also inflict punishment on those who are themselves tabu, like mourners, if they do not observe the restrictions proper to their condition; in this case the object is to deter others as well as to punish.

Acquired tabu is not necessarily permanent, it may be got rid of by taking the proper steps; washing is a common method of desacralisation. In Tonga the common person who touched a chief purified himself by touching the foot of a higher chief and then washing; or the infection of tabu may be treated as a more material substance. In New Zealand a chief who touched his head—a specially tabu part of the body—with his fingers could make his hand fit for profane purposes by putting it to his nose and snuffing up the air as though the tabu were a kind of effluvium. Where the condition of tabu is ascribed to the action of a spirit there are also means of removing it; a Melanesian mourner may leave his village for a length of time, and the spirit of the dead man, getting tired of waiting for him, may go away and leave the man free to return.

(2) The field of tabu in the wider sense is too vast for more than the most cursory survey. Some of the ritual prohibitions incumbent on uncivilised or semi-civilised peoples all the world over may be treated as rites of transition, that is to say as ceremonies destined to protect human beings at important epochs of their lives against the dangers that lie in wait for them. If we take rites of initiation we find that the essential element is that the candidate has to be transferred from the ranks of youths to those of adult men. This is effected by, firstly, removing the youth from the profane world to an initiation 'school,' where he has to observe many ritual prohibitions in addition to acquiring new knowledge; at the termination of this period he must be transferred back from the world in which he has been living, but now enters another section of the profane world. The passage from one world to another is often symbolised by such acts as entering the 'school' by a door which marks the point at which the two worlds meet; when he passes it the youth becomes tabu, and when he passes it in the reverse direction he must undergo a rite of desacralisation. The same scheme can be applied, with appropriate modifications, to a multitude of cases; betrothal and marriage are open to a similar interpretation; through childbirth and death a being enters a, for him, new world, which sets up a complex of prohibitions; even the simple occupation of a new house must not be undertaken without removing the tabu that rests upon it; at his accession a chief or king submits to ceremonies which separate him from the common folk and fit him for his high office; the stranger, when he comes within the gates, may cause or incur all sorts of dangers and undergoes appropriate treatment; and so on. But these cases represent only a small part of those involving tabus of one kind or another. One side of Totemism (q.v.) is the system of ritual prohibitions which regulate the dealings of a man with his totem. There may be a vast complex of rules regulating a man's behaviour in many circumstances of life, such as the *uso ani* of the Ibo, which are virtually their code of morality on one side, regulating whom a man may marry, deciding what children must suffer death (e.g. twins), &c., but also dealing with such apparently trivial matters as the crawling of a child through a gutter hole.

(3) Tabu therefore presents itself from one point of view as a complex of negative injunctions, but it would be a mistake to suppose that it can be viewed as wholly negative. Not in Polynesia only, but also in Africa and other parts of the world, tabu

represents in some respects the beginning of law and order; for a chief who would not intervene to help an individual if he were asked to do so simply as a guardian of law and order is nevertheless compelled to take steps when a tabu is broken. Property is thus protected by putting on it a tabu, and if the fear of direct penalties does not deter an offender he has always to look forward to being compelled to pay an indemnity to the chief or other person whose tabu he has violated. Personal rights, no less than the rights of property, can, it is clear, be enforced in the same way, for the weakling who is protected by the tabu of a chief is as secure as he would be under a more elaborate system of law.

Tabu has also been operative in another direction long after it ceased to be a living force; the sense of moral obligation remained behind when belief in the sanctions of tabu faded away; it laid the foundations of the influence of the categorical imperative. It must, however, also be recognised that much of what is vaguely called superstition may be due to the lingering effects of dead and gone tabus; an action forbidden for fear of supernatural penalties became, in process of time, unlucky—a deed which men shrink from doing, though they can formulate no valid reason for abstaining.

Tabu has also had, at least in certain areas, great influence on language; in Mimaassa a word that forms part of, e.g., a father-in-law's name, or even resembles it, may not be used by the son-in-law; among the Zulu the system of *hlonipa* in a similar way causes words to go out of use among a whole tribe; so too the names of dangerous or destructive animals tend to be replaced by synonyms or euphemisms.

Tabus of one kind or another are all but universal. Among the Jews tabus were incumbent on the high priest, the Nazirite, &c.; a leper, one who touched a corpse, and a bystander at heathen rites were tabu; iron was not to be used in the temple, a field was not to be sown with different herbs, &c. Among the Romans the *flamen dialis* and his wife had to observe all sorts of tabus. In modern times it was at its height in Polynesia at its discovery. It exists in one form or other in Melanesia, Indonesia, Australia, India, Africa, and America. In fact it is almost a necessary corollary of a belief in supernatural power.

It cannot be said that any general study of the subject exists, but reference may be made to the article in the *Encyclopædia Britannica* and the literature cited there, especially Frazer's *Golden Bough*, van Gonne's *Tabou et Totémisme à Madagascar*; descriptions of tabu in individual cases will be found in Langsdorf, *Reise um die Erde*; Codrington, *The Melanesians*; Maass, *Bei lebenswichtigen Wilden*; Internationales Archiv für Ethnographie, vii. 232-3; Handbook of American Indians, s.v. 'Taboo'; &c.

Tacahout, an Arab name for the small gall formed on the Tamarisk tree, used as one source for obtaining Gallic Acid (q.v.).

Tacamahaca. There is a good deal of confusion in botanic and commercial circles as to the trees which produce this resin, for Elemi (q.v.) and other resins are often confounded with it, most of these being produced in Brazil by different species of Icica. The fragrant bitter resin from Brazil is chiefly yielded by *Protium heptaphyllum*, but other species, as *P. guianense*, *P. icicaria*, &c., furnish a similar resin, known locally as 'almaceja,' which is used in medicine and the arts, and burned as incense in the churches. One Tacamahaca, from *Bursera tomentosa*, sells in Mexico at a good price, and is called Caricari in Venezuela. *Calophyllum Calaba* and others of its genus yield East Indian tacamahaca, which somewhat resembles species of olibanum, and gives off a similar odour when heated. The Mexican tacamahaca is usually called shell-tacamahaca, but is

better known as Elemi. *Populus balsamifera* is termed the Tacamahac poplar, but it yields little or no resin, the leaf buds only being used in ointments to prevent rancidity.

Tachylite, a black opaque natural glass, which results from the rapid cooling of molten basalt. It occurs as a thin selvage to dykes and veins of intrusive basalt—the latter having cooled rapidly from contact with the adjacent rocks. In Hawaii it appears as a scoriaceous or a compact crust, 2 inches or less in thickness, upon the basic lavas of that region. Tachylite never forms lava-flows like the acidic glasses (Obsidian). See BASALT.

Tacitus, the historian, is known to us chiefly from autobiographical touches in his own writings and from allusions in Pliny's letters. His full name is matter of doubt—Cornelius Tacitus being his nomen and cognomen; but whether his prenomen was Publius or Gaius can only be conjectured. Born perhaps at Rome (less probably at Terni) under the Emperor Claudius between 52 and 54 A.D., we infer that his family was respectable from his education, his profession, and his marriage. He studied rhetoric in Rome under M. Aper, Julius Secundus, and, likely enough, Quintilian; rose to eminence as a plender at the Roman bar; and in 77 or 78 married the daughter of Agricola, the conqueror and governor of Britain. To this alliance he doubtless owed the accelerated promotion which, beginning with a quaestorship under Vespasian, made him praetor in 88 A.D. and a member of one of the priestly colleges. Next year he left Rome, probably for Germany, where, doubtless as governor, he must have acquired his knowledge of the features, natural and social, of the country; and he did not return till 93, when he found his father-in-law had recently died. We know him to have been an eye-witness of Domitian's reign of terror, almost blaming himself, as a senator, for complicity in that monster's judicial murders of such exemplary citizens as Helvidius and Senecio, and we have his own testimony as to the blessed change wrought by the accession of Nerva and Trajan. Under the former emperor he became consul suffectus, succeeding the great and good Virginus Rufinus, on whom he delivered in the senate a splendid *oratio funebre*. In 99 A.D., conjointly with the younger Pliny, he prosecuted the political malefactor, Marius Priscus, and the 'characteristic dignity' with which his share of the prosecution was conducted won him the thanks of the senate. After this we lose sight of him, but may assume it as certain that he saw the close of Trajan's reign, if not the opening of Hadrian's. The high reputation he enjoyed in life is attested by the eulogistic mention of him repeatedly made in Pliny's letters, and in the third century the Emperor Tacitus, proud to claim kinship with him, built in his honour a tomb which was still standing in the later decades of the 16th century, when it was destroyed by Pope Pius V. The same emperor also issued an edict by which the works of his namesake were to be copied out ten times yearly for presentation to as many public libraries.

In spite of this multiplication of copies we possess but a moiety of what he wrote. His earliest work, the *Dialogus de Oratoribus*, treats, in conversational form, of the decline of eloquence following on the change for the worse in the education of the Roman youth under the empire. This, published in 76 or 77, was for some time suspected to be from another pen, but is now included in every edition of his works. It has reached us entire. Next comes the *Agricola*, the literary character of which it is difficult to define. Quite a library has accumulated on the question whether it is a 'laudatio funebris,' or an 'apologia' written to

shield the memory of Agricola from the charge of servility, or a historical panegyric framed for political ends. As biography it has grave defects, while it cannot be brought under any of the three above-named heads without serious deductions. But it will always be read for its elevation of style, its dramatic force, its invective and its pathos. For English readers its interest is unique. The third work, the *Germania*, or *De situ, moribus, et populis Germaniae*, is a monograph of the greatest value on the ethnography of Germany. Faulty in geographical detail, it becomes characteristically strong wherever human interest emerges. Fourth in order are the *Historiae*, or the history of the empire from the accession of Galba in 69 A.D. to the assassination of Domitian in 97. Of the twelve books originally composing it only the first four and a fragment of the fifth are extant. Tacitus is at his strongest in this narrative. His material was drawn from contemporary experience; and though the imperial archives were closed to him, he had at command the personal information open to a man of his position, to say nothing of correspondence (as of Pliny), the 'laudationes funebres,' the 'acta diurna' (what we should call the 'gazette'), and the 'acta Senatus,' the Roman equivalent for Hansard. He had no sympathy with the empire, as indeed we gather from his earliest work. He yearned for the return of an aristocratic oligarchy—the Rome of the Scipios and the Fabii. He is, on this account, a partisan, but is able to justify the most trenchant contrasts between the greatness of Republican and the deterioration of Imperial Rome, which latter he contrasts disadvantageously with the freedom and simplicity of even barbarian Germany. To his peculiar satirical gift which often makes him a 'Juvenal in prose' he gives free rein from time to time; though even in his bitterest moods he never forgets he is a Roman—a certain *charminism* betraying itself in his tendency to minimise the defeats of his compatriots and even the number of their slain. He had no appreciation of the higher qualities of the Jews, and his attitude to the growth of Christianity is that of a prejudiced, if cultured Roman, who, recognising an overruling providence or supreme 'Necessitas,' will not stoop to weigh the evidence to which the new religion appealed. The qualities conspicuous in the *Historiae* are maintained in his last work, the so-called *Annales*, a history of the Julian line from Tiberius to Nero (14 A.D. to 68). Of their sixteen books only eight have come down to us entire, four are fragmentary, and the others lost. In these, as in all his writings, his avowed aim was to perpetuate virtue and to stigmatise baseness whether in word or deed; hence he professes himself so severe a censor of the imperial system; though he is not blind to the shortcomings of the later republic, under which the provinces, he admits, were worse off than under the empire. Of late, indeed, it has been maintained that as the representative of the decadent and justly superseded aristocracy, he was malignantly unfair to even the best of the imperial Caesars. Among the more obvious defects which lower his value as a historian are his weakness in geography and his carelessness as to strategic details. His style is the most strongly marked of antiquity—statuesque in outline, rich if somewhat too sombre in colouring, effective in antithesis, not seldom obscure from sheer condensation.

The standard complete editions are those of Orelli, Ritter, and Halm. Important modern English editions are those of Furneaux, and Fisher, while there are translations (with notes) by Church and Brodribb, G. G. Ramsay, and Moore. The *Lexicon Taciteum* (1903) of Gerber and Greef is useful. See also the studies by Boissier (1903; trans. 1906) and Müller (1912). The old

fable that Tacitus was a mere forgery by Poggio (q.v.) need only be mentioned. Fabia in *Les Sources de Tacite* (1895) sought to prove that Tacitus is overrated, that he makes bad omissions, and that he copies sentence after sentence from older authorities—in the *Historiae* from Pliny the elder, in the *Annals* from Aufidius Bassus and Cluvius Rufus.

Tack, a Scots law-term for Lease (q.v.).

Tacna, a province of Chile. In 1884 it was ceded by Peru for ten years, when a plebiscite was to determine which country it should belong to. As the plebiscite has never been taken, the province is still occupied by Chile (see PERU, *History*). Cession of Tacna to Bolivia would appear to be the only definite solution of the dispute. The soil is fertile, cocoa, coffee, sugar, cotton, and fruit being cultivated, and there is some sheep-rearing and mining. Area 9566 sq. m.; pop. 38,912. The capital, Tacna, 38 miles by rail N. of Arica (q.v.), has a pop. of 15,000. Here the Chileans won a victory over the Peruvians and Bolivians in 1880.

Tacoma, the third city of Washington state, stands on the east side of Puget Sound, by rail 145 miles N. of Portland, Oregon, and 18 S. by W. of Seattle. In 1880 Tacoma was a village with only 1098 inhabitants; by 1890 it was a flourishing city with miles of wide streets, large wholesale stores, numerous mills and factories, and a busy port. There are now huge planing, paper, and flour mills, and iron and lumber works. Tacoma is an extremely important port, with many steamship lines to the Orient and to South America. Pop. (1900) 37,714; (1920) 103,093. Behind the city an open valley runs towards where the beautiful volcano Tacoma (or Rainier) rises, from a ridge of snow-covered mountains, to a height of 14,444 feet.

Tactics, MILITARY, the science which enables one of two opposing bodies of troops to be stronger than the other at every crisis of an engagement. This may be due to superior numbers, favourable ground, better arms, a higher state of discipline and training, or anything else that, if used to the best advantage, will produce greater strength at the point where and time when it is most essential.

Strategy (q.v.), which has precisely the same objects, merges into tactics as the enemy comes within striking distance, and the latter science is therefore sometimes defined as the strategy of the battlefield. Modern writers use different terms for the various branches of tactical science: *grand tactics* or *manoeuvre tactics* deals with the methods of putting the chief units into the battle; *minor tactics*, with the conduct of small bodies, such as advanced and rear guards, outposts, patrols, &c.; *fighting tactics*, with the formations into which the regimental units dislocate themselves on entering the zone of fire; *fire tactics*, with the best use of guns and rifles, the massing of their fire, and the selection of the target; and the special *tactics of cavalry, artillery, or infantry, combined tactics, siege tactics, and mining tactics*.

It would be impossible to enumerate all the schemes and devices which go to make up this science, varying as they must with the arms in use and the manoeuvring power of the troops employed, but some illustrations may be given from ancient and modern history. In Judges xx. we read of a favourite and dangerous manoeuvre, the Israelites feigning to retreat before the Benjamites, so as to draw them on until their flanks and rear were exposed to the 'liers in wait.' Hannibal at Cannae and William the Conqueror at Hastings were among the many successful imitators of these tactics. Others, like the Duke of Burgundy in 1476 at Granson, lost their armies

through attempting it with unsteady troops. Fredrick the Great owed his victory at Mollwitz to the rapid fire and steady discipline of his men, and the former was chiefly due to the introduction of iron ramrods. His later battles give us good examples of manoeuvre tactics. At Lenthén he engaged the Austrians, immovable in their chosen position, with his advanced guard, while his main body, under cover of some hills and foggy weather, marched in open column of companies round their flank, wheeled into line, and rolled up their army. At Rossbach he showed how to defeat this manoeuvre when the enemy put it in practice. Sending his cavalry and artillery to check the head of their marching columns, he threw his main body upon their flank and inflicted a crushing defeat. At Kolin his *linear tactics* failed because the rear of his column wheeled into line too soon, leaving the head to continue the march, so creating a wide gap in the line when formed up. At Waterloo Napoleon showed an example of *combined tactics* on a large scale. By cavalry charges he obliged the British infantry to form squares, which then became targets for his massed artillery. When under stress of this 'hard pounding' they opened out into line, a renewed charge of cavalry obliged them to take the denser formation again. At Gravelotte the German armies (some 240,000 men) showed an unparalleled instance of *grand tactics* by marching to their positions across country in seven large masses, each consisting of one complete army corps. The *minor tactics* employed by advanced or rear guards and outposts are to a certain extent stereotyped. Their object is to prevent the main body—in the first case a column, often several miles long; in the second a large camp, cantonment, or bivouac—from being attacked before it can get into fighting order. Therefore a series of small parties of two to six men lead the way, or stand sentry, some four miles in front of the main body, while larger bodies support them at a little distance, followed in their turn by still larger units, so that the enemy meets with an ever-increasing resistance until he finds himself confronted by the main body drawn up in a carefully chosen position. *Fighting tactics* must depend chiefly upon the arms in use. The mail-clad horsemen of the 15th century never succeeded in defeating the solid phalanx of pikemen opposed to them by the Swiss Confederation until the employment of artillery prevented the latter retaining such a massive formation. The English archer, protected in front by palisades and on the flanks by spearmen, destroyed the chivalry of France at Cressy and Poitiers, but at Bannockburn was ridden down by the Scottish cavalry, because the flanking spearmen had been omitted. Gustavus Adolphus, by employing cartridges, enabled his infantry to fire more quickly than his opponent and so to form on a wider front. The invention of the bayonet, doing away with the necessity for pikemen to protect the musketeers, still further increased the fire-power of infantry. The British two-deep line overthrew, by its converging fire and charge, the column formation of the French in the Peninsula and of the Russians at Alma. In the battles of the Franco-German war of 1870-71 it was found impossible to advance against the fire of modern breech-loading rifles except by rushes of comparatively thin lines of skirmishers, constantly reinforced by supports and reserves in rear. The magazine rifle, smokeless powder, machine gun, quick-firing cannon, and enormous power of high-explosive shell still further complicate the problem, presented to the assailant, of closing with the enemy. No rules can be laid down except that there must be plenty of supports and reserves, and the closest co-operation between artillery and infantry.

In the Great War the multiplication of firearms and the vast development of entrenching led to experiments in attack. These culminated with us in the 'leap frog' system, whereby the first attackers were given limited, clearly defined objectives, company by company or platoon by platoon, further work beyond being entrusted to the next wave of assailants, and so on. In defence, the final tactics were to hold the first line lightly, so as to save men during the bombardment, and to make counter-attack from the second line before the assaulting troops had reformed in the first; at this time and place the attacker, so far successful, could not use his artillery.

Against enemy whose fire is not formidable, but the shock of whose charge is so, close order is the rule and the luring of him into the open. He is usually in superior numbers, and therefore ready enough to attack.

Cavalry tactics, now more like those of mounted infantry, consist greatly in using the horse for speed and then the rifle in the hands of dismounted troopers. Shock action is seldom possible, and differs from the charge of old days in the men riding in open order, and not boot to boot. *Artillery tactics* consist in concealment from hostile observers in and on land, close co-operation with one's own infantry, concentration of fire at short notice on any given target, the constant provision to the batteries of unlimited ammunition.

Siege tactics have lost importance in sieges proper, which operations, in relation to permanent works, have become almost entirely a matter of sheer demolition of everything by high-explosive shells (see under SIEGE). But the siege tactics of former days, included in the words sapping and mining, have appeared in the modern attack of entrenchments, whenever it was advisable not to risk *à l'assaut*.

See *Field Service Regulations, Part I.* and the *Training Manuals* of the War Office for infantry and artillery; for history of the subject, see Captain Johnstone's *A History of Tactics* and E. M. Lloyd's *History of Infantry*.

Tactics. NAVAL, is the art of manoeuvring ships and fleets in presence of each other for the purposes of battle; whereas naval strategy is the science of combining and employing fleets or single ships in order to carry out defined operations at sea or against an enemy's coast, for obtaining command of the sea or certain portions of it. Although fleets had existed and battles at sea been fought from the earliest periods, it was not until towards the close of the 16th century, in the reign of Queen Elizabeth, that naval war began to assume definite form. The discovery of the New World and the occupation of its richest territories by Spain, the opening up of the route to the East Indies by the Cape of Good Hope, and the efforts which English merchants began to make at this time to push their own trade gave a marvellous impetus to the sea-borne commerce of the world, which carried with it as a necessary consequence the building of larger and more seaworthy ships than had previously existed. War at sea at this time does not appear to have been carried on on any definite plan, and consisted principally, if we except the attempt of the Great Armada, of raids on the enemy's commerce and coast-towns. The first organised attempts to obtain command of the sea are to be found in the Dutch and English wars of 1652, 1665, and 1672, in which the honours were pretty evenly divided, each party striving to destroy the trade of the other; in the second war, Dutch merchant-ships were forbidden by the Dutch authorities to put to sea at all. Several efforts were made by the French, between 1690 and the defeat at Trafalgar, to obtain the command of the sea in order to effect the invasion of England. In

1690 the Earl of Torrington, forced against his better judgment, by direct orders from queen and council, to attack the vastly superior forces under Tourville, gave battle off Beachy Head. He was defeated, but skilfully drew off and fell back under shelter of the Gunfleet Shoals at the mouth of the Thames. Here, although 'beaten, inferior, and shut up behind sandbanks,' yet, from the strategic position he now held, his fleet still remained such a 'power in observation' as to paralyse the action of the victorious and superior force. Steam is often said to have revolutionised naval strategy and tactics, but this is only true in so far as changes in the motive-power of ships affect the times required to move from one position to another, and render such movements more certain; formerly the best-laid schemes were often frustrated by foul winds and gales, while now the great steam-power of battle-ships and cruisers renders them independent of wind and to a great extent of bad weather. As a set-off, however, to this, the coal endurance of ships and the replenishing of their supplies of fuel become important factors in deciding upon their movements.

The principal objects of Great Britain's naval strategy must be, first and foremost, to obtain the complete command of the sea, the destruction of the enemy's battle-fleets, and the protection of the great trade-routes. For this purpose a fleet of battle-ships strong enough to meet any hostile combination, supplemented by a proportionate number of fast cruisers, torpedo-boat destroyers and submarines, and air-craft, is indispensable. A deficiency in battle ships might cause us to lose command of the seas round our coasts, thus opening the way to invasion and endangering our very existence as a nation; while a poverty of cruisers would mean a sweeping of the country's trade from the sea—as happened to the United States in the civil war—and deprival of broadstuffs and most of the raw materials required for our manufactures. Eighty per cent. of the sea borne trade of the world is carried in English bottoms, and a few hostile cruisers and submarines, if not immediately hunted down, would in a short time work incalculable havoc, as was proved by the operations of the Germans in the Great War.

During the war between Spain and the United States in 1898, the Spanish Admiral Cervera, with his squadron of four armoured cruisers and two destroyers, was blockaded for more than a month in Santiago de Cuba by a much superior squadron under Rear-Admiral Sampson, whose ships were cruising on an arc of a circle some seven miles off the harbour. In the forenoon of 3d July Cervera came out and made a dash for liberty, and he would probably have succeeded in making his escape, in view of the distance Sampson's ships were keeping offshore, but for the loss of speed of his little squadron due to the foul state of their bottoms; as it was, he was intercepted and his ships driven on shore and destroyed. This was a case of genuine blockade. Observation of the enemy's ports now takes the place of close blockade; this being carried out by a chain of cruisers, submarines, air-craft, and destroyers in touch with the main body of the fleet. Such touch is now easily maintained by means of wireless telegraphy, which has been brought to such a pitch of perfection as to revolutionise the art of scouting at sea.

The triremes or galleys of the ancients were armed with formidable iron or brass beaks; propelled by oars, they were formed for attack with their bows pointing to the enemy, the aim being to destroy by an oblique blow the oars on one side of the enemy, and then ram and sink her. At Salamis (480 B.C.) the superior tactics of the numerically inferior Greek fleet inflicted a crush-

ing defeat on a vastly superior Persian force (see NAVY). The secret of tactical success is to throw an overwhelming force, if possible, on some point of the enemy's line, and destroy him in detail: as at Sluys in 1340, when Edward III., having successfully manœuvred to bring his line obliquely across the right wing of the French, completely crushed it. At Lepanto in 1571, Don John of Austria, mainly by his skilful tactical arrangements, completely defeated the Turks. He divided his fleet into three squadrons, which were formed in line abreast, with sufficient room between each for manœuvring; in rear was a reserve squadron. The Venetian admiral, before the action commenced, placed six galleasses (see GALLEYS) about half a mile in advance of the fleet, two in front of each of the three divisions; the heavy ordnance of these vessels effectually broke the shock of the Turkish onset. Taking advantage of their confusion, Don John pierced their centre, and the rout of the Turks was complete, although the commanders of both the Turkish ships displayed considerable tactical skill. The Christian left wing was for a time outflanked and placed between two fires, while the Turkish left wing passed through the Christian line, and, but for the reserve squadron by which it was immediately attacked and driven back, might have altered the fate of the day. Lepanto was the last great battle in which galleys took a prominent part. With 'great ships,' dependent on their sails alone, having their guns mounted on the broadside, a new method of organising fleets for battle came into being. It was not, however, until the wars between the Dutch and English of 1652-72 that the tactical formation of a fleet in 'line of battle' was devised. Previous to this, fighting at sea appears to have been carried on in rather an indiscriminate fashion, although from the first the obtaining of the weather-gauge seems to have been recognised as the great aim for which to manœuvre. Sir W. Monson, a distinguished sea-captain of Queen Elizabeth's time, writes: 'For the greatest advantage in a sea-fight is to get the wind of one another; for he that has the wind is out of danger of being boarded, and has the advantage where to board and how to attempt the enemy.' According to Admiral Colomb, the 'line' was first introduced by the Dutch as a means to weaken the power of fireships, and to bring the fleet under better control. The line of battle consisted in a fleet of ships being extended in a straight line either ahead or abreast one ship of another, keeping as close together as weather permitted, so that at all times every ship should be ready to sustain and relieve one another. It was directed that each ship in the line should keep within half-a-cable's length (about 50 fathoms) of one another. It was introduced into the English navy by Sir William Penn. According to Pere Hoste, it was the formation taken up by both English and Dutch in the battle of the 29th July 1653, and by the Duke of York in the battle off the Texel in June 1665. But it was dropped again by Albemarle in the battle of June 1666; and, by the way Sir W. Penn speaks of it (see POPYS), it seems clear that there was still controversy as to whether a line was or was not the best formation for a fleet for fighting purposes. So, although the line was established on paper as the fighting formation soon after the outbreak of the first Dutch war, it probably did not get firm hold until the third Dutch war. However, as a recognised order of battle it was embodied in the Duke of York's fighting instructions issued in 1665. These instructions were modified by Admirals Russell and Rooke at the end of the 17th and the very beginning of the 18th century, and Rule XIX. ran: 'If the admiral and his fleet have the wind

(or weather-gauge) of the enemy, and they have stretched themselves in a line of battle, the van of the admiral's fleet is to steer with the van of the enemy's, and there to engage him, each ship from van to rear successively.' It was for acting contrary to this rule that Admiral Matthews was tried by court-martial and cashiered after his indecisive action with the French off Toulon on the 22d February 1744. His fault, for which he was condemned, was breaking (or quitting) his own line with the signal for the line of battle still flying; having formed his line, he broke it himself by running down to attack the French and Spanish centre. Admiral Lestock, the second in command, refused to obey. Both were tried, and Lestock was acquitted. These instructions were still in force in 1781, when Admiral Graves fought his action off the Chesapeake on the 5th September. And on the 5th July 1782 Sir Edward Hughes, in the East Indies, tried to engage the French fleet under Suffren according to Rule XIX, when he had the chance, but failed. According to Professor Loughton, they were not issued after that time. Admiral Rodney on the English side and Suffren on the French had shown that it might be better to leave a commander-in-chief free to act as the occasion required. These instructions also made no provision for engaging from the position to leeward. It would seem that the idea in Russell's and Rooke's minds was that the fleet to windward, whichever it was, was to engage. As a matter of fact, the French never engaged in that way, and as a rule utilised the position to windward to avoid action, as in Admiral Keppel's action in 1778, and in Rodney's two actions with Guichen in May 1780. The system of tactics put in practice by Sir George Rodney in his action with the French under the Comte de Grasse on the 12th April 1782 was by a curious coincidence used on the same day by the French admiral Suffren against the English squadron under Sir E. Hughes in the East Indies, the result of which was to free British admirals' hands, leaving it to their discretion how best to attack the enemy. This was simply concentrating the attack on a part of the enemy's fleet instead of dispersing it along the whole; there was nothing new in this or in the manoeuvre by which it was effected, which was cutting through the enemy's line.

The honour of having been the first to demonstrate fully the principles on which the manoeuvres of an attack against fleets to windward or to leeward depend is generally ascribed to John Clerk (q.v.) of Eldin in 1779; though English commanders cut the enemy's line as early as the middle of the 17th century. In 1652 Sir George Ayscough pierced the Dutch line from to leeward; in 1665 the Earl of Sandwich cut through the centre of the Dutch line; in 1672 Sir J. Jordan, having the weather-gauge, cut through the Dutch fleet and threw it into confusion. But it was Rodney's victory over the French in 1782 which gave the manoeuvre notoriety. The idea was suggested to the admiral by Sir Charles Douglas on perceiving an opening between two of the ships near the French centre. The opportunity was seized of passing through; so narrow was the opening that the admiral's ship almost touched the French ships on each side; the ships astern followed him closely, and these kept up a powerful raking fire against the ships in the rear division of the enemy's fleet, which, being driven to leeward as the van of the British passed through, broke up and made sail before the wind to escape. At the battle of the Nile (1798) Nelson doubled on the van of the French line and attacked it on both sides, while the other ships, the whole fleet being at anchor, could afford no assistance; but at Trafalgar he

broke the enemy's line in two places, bearing down upon it in two columns. The enemy's centre and rear were overwhelmed, the van being unable to come to their assistance.

Since the introduction of steam and armour-plating there have been but few naval battles affording opportunity for the display of tactical handling of ships. In 1866 the Italian fleet under Persano, consisting of eleven ironclads, four wooden frigates, and some small vessels, was bombarding Lissa, when on the morning of the 4th July the Austrian fleet under Tegethoff was sighted. Persano formed his ironclads in line of battle—the old 'line ahead'—in single column, nearly at right angles to the course the Austrians were steering; Albini, his second in command, acting on the understanding that wooden ships should not unnecessarily engage armoured ships, kept well out of the way and practically took no part in the action. Tegethoff formed his seven ironclads in double quarter line, his flagship, the *Ferdinand Max*, leading and forming the apex of the wedge; following in the same formation, at a distance of about 1000 yards, came seven wooden ships; in rear of these again came seven gun-vessels. Persano trusted to his gun, Tegethoff to the ram. Steaming at full speed, Tegethoff, who had previously explained his plans to his captains, made the signal, 'Ironclads to rush against and sink the enemy.' The Italian line was badly formed, and the Austrians passed through a large gap in the centre. In the mêlée which ensued, the *Ré d'Italia* was rammed and sunk by the *Ferdinand Max*, the *Palestro* was set on fire and blown up, and the Italians, now thoroughly disorganised, were driven to take refuge in Ancona. Naval opinion came to the conclusion that the ram was more formidable than the gun, and that 'line ahead' was no longer suitable as a battle formation. But it was overlooked that the *Palestro* had been sunk by gun-fire, and that if the *Ré d'Italia* was rammed, it was because for the moment she had also been rendered unmanageable from the same cause. The advent of the torpedo and the vastly increased range and power of modern guns have killed ramming tactics, and the war of 1904-5 between Russia and Japan proved that, now as in the past, there is only one weapon of offence for the fighting ships, and that is the gun.

The action of 3d July 1898, off Santiago de Cuba, when Cervera's squadron was destroyed, was not a tactical engagement in any sense of the word; it was simply the chase and destruction of slower and inferior ships by faster and more powerful ones. In the two great battles between the Russian and Japanese fleets, on the 10th August 1904 and the 27th May 1905, we find: 1st, that the decisive factor in each action was not the ram, nor the torpedo, but the gun; 2d, that single column in line ahead—the one formation which allows the whole broadside of a ship to be most effectively brought into action—was the battle-ship formation adopted by both Togo and his Russian opponents. The aim of the Russian admiral on the 10th August was to break through the Japanese and escape to Vladivostok; of Togo, to foil the attempt. Rear-Admiral Vithöft led the Russian line of six battle-ships in his flagship, the *Cesarevitch*, while Togo in the *Mikasa* headed the Japanese line of four battle-ships and four armoured cruisers. Fire was at first opened at ranges varying from 11,000 to 8000 yards; later the distance was decreased to 3500 yards, and at first both sides seem to have concentrated their fire against each other's flagship, which were leading. About 6 P.M. a shell from the *Mikasa* burst close to the conning-tower of the *Cesarevitch*, killing the admiral and disabling her steering-gear; her helm jammed and the ship sheered off to port, and the whole Russian

line was at once thrown into confusion and their formation broken up. The result is known; the *Cesarevitch* found her way into the German port of Tsingtan, and the other five Russian battle-ships were forced back to Port Arthur. In the battle of the 29th May 1905, in which Togo annihilated the Russian fleet under Admiral Rozhdestvensky, the two divisions of Togo's fleet, each consisting of six armoured ships, which attacked the Russians, the one from ahead and the other from astern, were formed in single column in line ahead. The Russians opened fire about 2 P.M. at 12,000 yards, but it was quite ineffectual; the Japanese reserved their fire until within 7500 yards, and so accurate was it that by sunset three of the Russian battle-ships were sunk and the rest of the fleet hopelessly disorganised; so that, with the exception of four unarmoured cruisers, the whole fleet, which when the fighting began consisted of five first-class battle-ships, three second-class, and three const-defence ships, with three armoured cruisers, had been sunk or captured. The Japanese fleet consisted of four first-class battle-ships, eight armoured cruisers, some smaller vessels, and a large force of torpedo-boats, which were launched with great effect against the Russian ships during the night of the 27th-28th.

During the Great War, 1914-18, the few naval actions demonstrated the value of accurate fire at very long ranges, the value of high speed, the influence on tactics of torpedo attacks by masses of torpedo boat destroyers, and the influence of mines and submarines on the mobility of fleets. At *Coronel* Von Spee overpowered and sank Cradock's squadron by superior gun-power and speed. At *Falkland Islands* Stander overpowered Von Spee by superior gun-power and speed, sinking all his squadron except *Dresden*. At *Dogger Bank* Beatty chased and overtook the Germans under Von Scheer and sank *Blucher*, but owing to *Lynn* being disabled, and the menace of mines and submarines causing the rest of his cruisers to abandon the chase, three German battle-cruisers escaped though injured. At *Jutland* Beatty engaged the German battle-cruisers, and fought a running action until the German main battle-fleet was sighted. He then altered course 16 points, and led them to meet Jellicoe's grand fleet, but a determined massed attack of German torpedo-boat destroyers interfered with the deployment of Jellicoe's fleet and somewhat delayed forming line ahead, and efficient range finding and range keeping was marred by mist and failing light, resulting in the Germans managing partly to evade the grand fleet and escape into harbour; but before the mist came on very considerable damage was inflicted on the Germans, who were also mauled by torpedo craft during the night of 31st May 1916, after the action, when steering for Horns Reef. The German fleet never attempted to give battle again. When ordered out to fight, the battle-ships' crews untied and refused to go. They finally surrendered to the grand fleet when the armistice was arranged.

In these actions line ahead formation was the battle formation, and the general idea was to manoeuvre the line so as to cross at right angles to the course of the enemy's line—called crossing his T; but when chasing it developed into quarter line, and, owing to differences of speed, intervals were lengthened. Ranges varied between 21,000 yards and 11,000. The general idea, if visibility permitted, was to keep outside torpedo range—i.e. outside about 15,000 yards, but occasionally they got within 8000 yards. Sea-planes were used by the grand fleet at Jutland during the approach, and did good service. Kite-balloons were introduced for spotting fall of shot, and the Germans used an

air-ship; but after Jutland the use of air-craft, in conjunction with the grand fleet, for scouting and for spotting fall of shot was greatly improved, and special vessels were designed and built to carry and work air-craft—e.g. *Argus*, *Renown*, &c. In future naval actions, air-craft will undoubtedly be extensively used both for scouting and bomb-dropping, and will no doubt influence tactics.

It seems clear that the gun has resumed once more its old position as the determining factor in naval battles, and the tactics of commanders must be such as to give the best effect to this weapon. Tacticians look to the single column in line ahead as giving the gun its best opportunity, and of being the best formation not only for affording mutual support, but for concentrating an overwhelming fire on one part of the enemy. The fleet that has a superiority in speed must necessarily, if well handled, have certain advantages over a slow one: it gives the power of accepting or refusing action; it enables the fleet possessing it to take up the most advantageous position as regards sun and wind. And superior speed should give the opportunity of concentrating a superior force on some given point of the enemy's line and crushing it.

Tadcaster, a market-town in the West Riding of Yorkshire, on the Wharfe, 9 miles SW. of York. At Towton, 2½ miles S., the Yorkists gained a great victory in 1461.

Tadema. See ALMA-TADEMA.

Tadmor. See PALMYRA.

Tael, a weight of silver of a certain fineness or touch used as a Chinese money of account, and represented by no actual coin. There are altogether about 170 forms of taels, of which the four principal are the *Hakwan* or customs tael, an arbitrary standard only used for calculating the duties levied by the maritime customs, worth now from 8s. 6d. to 4s., and weighing 583 grains; the *Keping* or treasury tael, in which under the empire all dues were paid, except the customs and those paid in kind and in copper cash; the *Tsaoping* or Shanghai tael, in which the banks quote foreign exchange rates; and the *Canton* tael, used for weighing bar silver in Hong-Kong, Shanghai, and Canton. The tael was originally of importance in establishing some sort of financial standard, but both before and after the revolution there reigned intense currency confusion, and it has been proposed to establish a Chinese silver dollar of uniform value throughout the country.

Taenia. See TAPEWORM.

Taffeta, or TAFFETY (Persian *tāfta*), a term formerly applied to all plain silks simply woven by regular alternations of the warp and weft, came to be used for almost all 'plain silks,' or even for various combinations of silk and wool, and now generally means a thin glassy silk with a wavy lustre.

Taff Vale. See TRADE UNIONS (*Legal Position*).

Tafflet. See MOROCCO.

Taft, WILLIAM HOWARD, American president, was born at Cincinnati in 1853, his father having been a member of President Grant's cabinet. He studied at Yale, qualified as a barrister at Cincinnati, held numerous posts in Ohio, and in 1890 became Solicitor-general for the United States. In 1901 he was appointed first Civil Governor of

the Philippine Islands; in 1904-8, was Secretary of War; in 1906, Provisional Governor of Cuba; and as a republican was President of the United States 1909-13. He stood for a second term of office, but was defeated by Woodrow Wilson; thereafter he became Professor of Law at Yale. In 1921 he was made Chief Justice of the United States. He strongly supported the movement for reciprocity with Canada.

Taganrog, a seaport of Ukraine, in the Don country, on the north shore of the Sea of Azov. The port has now silted up considerably, but there is still an important trade in grain, linseed, &c. Tebekhov was a native. Pop. 70,000.

Tagliacozzi, or **TALIACTIUS**. See RHINOPLASTIC OPERATIONS.

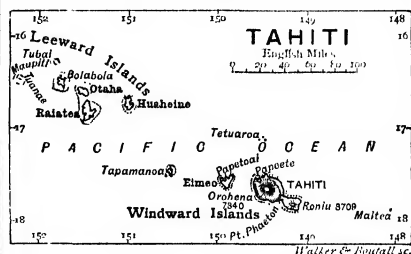

Taglionti, MARIA (1804-84), a celebrated dancer, born at Stockholm of Italian parents, her father being a ballet-master. She made her debut in Paris in 1827, and appeared with enormous success in all the large European capitals. She married Comte de Voisins in 1832, and retired with a fortune, afterwards lost. Her brother Paul and his daughter Maria were also famous dancers.

Tagore, RABINDRANATH, was born in 1861, of an ancient Bengal family. For some time he managed his father's estates in the country, and later founded a school at Bolpur, near Calcutta, since developed into an international institution. In 1913 he was awarded the Nobel Literature Prize. A knighthood was conferred in 1915, which in 1919 he asked in vain to have revoked. In Bengali he has written about thirty poetical and twenty-eight prose works (novels, essays, pamphlets, &c.), some of which he has translated into English. His best-known volume of poetry is *Gitanjali*, and other books are *Fruit-Gathering*, *Siddhanta*, *The Gardener*, *The Crescent Moon*, and a volume of *Reminiscences* (1917). His writing is intimate, personal, mystical, and, on the whole, sympathetic to nationalist aims and aspirations. See Study by E. J. Thompson.

Tagus (Span. *Tajo*; Port. *Tejo*), the largest river of the Spanish Peninsula, rises on the frontier of the provinces of Guadalajara and Teruel, on the western slopes of the Muela de San Juan. It first flows north-west, then curves to the south-west, and flows mainly in that direction past Aranjuez, Toledo, and Alcantara, and in Portugal, Abrantes, Santarem, and Lisbon, entering the Atlantic about 10 miles lower down. Below Salvaterra it divides into two arms, the western Tejo Novo and the eastern Mar de Pedro, which form a delta, the *Lezírias de Tejo*. Both fall into the noble Bay of Lisbon, which turns to the west and joins the sea by the *Entrada de Tejo*. It is navigable to Abrantes, from Santarem for steamers, even ocean-going vessels. Its total length is 566 miles; its drainage area includes 31,700 sq. m.

Tahiti, an island giving name to a small archipelago, also called Society Islands, in the middle of the Pacific, more than 2000 miles N.E. of New Zealand and some 3400 S.W. of San Francisco. The islands consist of Tahiti, which embraces 600 sq. m. out of a total of 900 for the entire archipelago, and a number of smaller ones, the chief being Raiatea and Eimeo (q.v.). The group is divided into two clusters, called respectively the Windward and the Leeward Islands, and stretches for about 200 miles in a north-west and south-east direction. They are composed of volcanic rocks, are mountainous (Orohena on Tahiti is 7340 feet high), and well wooded, with belts of low fertile soil along the shores. Coral-reefs encircle the separate islands, some of which are atolls, and numerous

cascades foam down the mountain-sides. The scenery is magnificent, the chief island being often called 'the Garden of the Pacific.' The climate is very moist and hot (range 70° to 84° F.), but equable and healthy. Coconuts, oranges, vanilla, and all kinds of fruit are grown, as well as some cotton and sugar. Besides these things mother-of-pearl (the most valuable of all), coconut fibre, and phosphates are exported, while the most important imports are tissues, wheat, live-stock, and metal work. The people cultivate for their own sustenance the bread-fruit, taro, yam, sweet potato, &c. There are several good harbours behind the

shelter of the reefs; the most important is Papeete, the capital of the archipelago, which stands on the north-west of Tahiti, and has a Roman Catholic cathedral, an arsenal, schools, and a population of 4600. The population of Tahiti is 7145 (1924), and of all the islands together, though more than half are wholly uninhabited, about 20,000. The people, a handsome race of the Polynesian stock, are light-hearted, polite, and gay, but very immoral and untrustworthy; formerly, before they became so thoroughly Europeanised as they are now, they were notorious for their cruelty. The group was discovered by the Spanish navigator De Quiros, but first accurately described in detail by Cook (1769-77). He gave the name of Society Islands in honour of the Royal Society of London on the occasion of his first visit; at that time the population numbered nearly a quarter of a million. The London Missionary Society commenced work in these islands in 1797. But they have had unusual difficulties to contend against, and in 1812 they had to flee for a while to Australia. In 1842 the French forced a protectorate over the eastern cluster, subsequently extended to the whole group, which was made a colony in 1897 and united in 1903 with other establishments in Oceania.

See Cook's *Voyages*; *Quest and Occupation of Tahiti* (trans. Corney, from Spanish despatches, &c., Halsbury Soc. 1913-19); Desgraz, *Iles Tuai* (1844); Ellis, *Polynesian Researches* (1829); Williams, *Missionary Enterprise on the South Sea Islands* (1839); Pritchard, *Polynesian Reminiscences* (1866); Dora Hort, *Tahiti: the Garden of the Pacific* (1891); and books by Calderon (1921), and Keable (1925).

Taiichu, an inland town on the western side of Formosa, about midway by rail between Taipei and Tainan. Pop. 32,000.

Taihoku, or **TAIPEI**, since 1887 the capital of Formosa (q.v.), 13 miles by rail from Tamsui on the north coast. The Japanese have spent large sums of money on Taihoku, and it is now an extremely prosperous and well laid out town with a busy commerce, especially in tea, camphor, sugar, and coal, and with numerous important government buildings, hospitals, schools, banks, &c. Pop. 187,000.

Tail, and **Tailzie**. See ENTAIL.

Taillandier, SAINT-RENÉ (properly René Gaspard Ernest), a French writer (1817-79), born at Paris, studied at Paris and Heidelberg, and had already filled chairs at Strasburg and Montpellier, when he was called in 1863 to succeed Saint-Marc Girardin at the Sorbonne. He was admitted to the Academy in 1873. His chief work was to open up the art and literature of Germany to his countrymen in such books as *Histoire de la jeune Allemagne* (1849), *Études sur la révolution en Allemagne* (1853), *Allemagne et Russie* (1856), and a translation of the Goethe-Schiller letters (1863), besides writing many volumes of essays, philosophical, literary, and historical.

Tailor-bird (*Orthotomus sutorius* or *Sutoria sutoria*), a bird belonging to the family Sylviidae. The male is about 6½ inches long; the general colour is olive-greenish; wings brown, edged with green; the two central tail feathers are long. It

Tailor-bird (*Orthotomus sutorius*).

is common in gardens, hedgerows, orchards, and low jungle in India, Burma, and China, being found usually in pairs, but sometimes in small flocks. The name tailor-bird is derived from the way in which the nest is formed. Two or three leaves are stitched together by means of silk from cocoons, thread, wool, or vegetable fibres, the necessary holes being made by the bill. In the cup thus formed the nest is made, and consists of cotton-wool with a few horse hairs and some fine grass. The eggs are three or four in number, and are of two distinct types, the ground of the one being reddish white and of the other pale bluish green. The latter type is the rarer, and the two kinds of eggs are never found in the same nest.

Tain (Scand. *Thing*, 'a place of assembly'), an ancient royal burgh of Ross-shire, near the south shore of the Dornoch Firth, 44 miles NNE. of Inverness by the Highland Railway (1864). A ruined chapel marks the birthplace of St. Duilach (c. 1000-65), whose body was brought back from Armagh in 1253; within it Bruce's queen was taken captive for Edward I., and James IV. did yearly penance here. There are also a collegiate church (1471; restored 1849-82), a court-house (1849), a public hall (1876), and an academy (1812). Pop. (1861) 2319; (1921) 2394. As a parliamentary burgh (till 1918), Tain united with Wick, Dornoch, Dingwall, Cromarty, and Kirkwall to return one member. See Taylor's *History of Tain* (1882).

Tainan (until 1889 TAIWAN) is the oldest city in Formosa (q.v.) and was the capital for two centuries under Chinese rule. It contains law courts, a hospital, several schools, and has been much improved as a town since the Japanese

occupation. With its port Anping, 3 miles W., it was one of the last places to fall to the Japanese in 1895. Pop. 83,500.

Taine, HENRI, French critic, so styled first through a whim of the editor of the *Revue des Deux Mondes*, his real name being Hippolyte Adolphe Taine, was born at Vouziers in Ardennes, 21st April 1828. He studied at Paris at the Collège de Bourbon and the École Normale, but his religious opinions barred the way to a scholastic career commensurate with his abilities. He filled minor parts at Toulon, Nevers, Poitiers, but soon threw up the state educational service to return to Paris, where after a short time of struggle he conquered fortune by the sheer strength and originality of his literary work. He took his *Docteur ès Lettres* in 1853, writing for the occasion, besides the regular thesis, a treatise on Lafontaine's *Fables*—a masterpiece of critical analysis which established his reputation. Here at twenty-five he had reached the critical method which was to dominate him throughout life. His method is to make a searching investigation into the race, social conditions, and antecedents of the individual, his environment, the special tendencies of the age and their bearing upon him. These supply the key to the fundamental quality—the *faculté maîtresse*—of the author, which, once grasped, the critical judgment is complete and unassailable. But unfortunately *race, period of time, and environment* give completely different combinations to the reading of different observers, and with the help of all these it is only possible to see what one wishes or expects to see. The individuality is a subtle essence which eludes all this pretentious analysis, and these vast generalisations remain mere preconceived theories and foregone conclusions, the process the very opposite of the objective, the scientific, the certain. In 1854 Taine won the Academy's prize for an essay on Livy—an audacious application of the same critical method to a period of which he did not possess adequate knowledge. His *Voyage aux Eaux des Pyrénées* (1855) and *Voyage en Italie* (1866) are books that stand almost first of their class. In 1863 Taine was appointed to an examinership at St. Cyr; in October 1864 he became professor of *Æsthetics and the History of Art* at the École des Beaux-Arts in Paris, thus finding a motive for his well-known subtle and paradoxical books on the Philosophy of Art, the Ideal in Art, and the Philosophy of Art in Italy, in Greece, and in the Netherlands. Already an Oxford D.C.L. (1871), was elected to Loménie's chair in the French Academy in 1878; he died 5th March 1893. Some of his maturest critical work is to be found in the *Essais de Critique et d'Histoire* (1857) and the *Notions des Essais* (1865); his most vigorous polemic in *Les Philosophes Français du XIX. Siècle* (1856), an attack on Cousin, Jouffroy, &c. The *Notes sur l'Angleterre* (1861) is perhaps his best book of its class, spite of its cleverness a warning example of the folly of splendid inductive theories without adequate knowledge. His famous *Histoire de la Littérature Anglaise* (5 vols. 1863-64; Eng. trans. by H. Van Laun, 4 vols. 1872-74) excited a clerical storm in France which cost him the Academy's prize of 4000 francs. The work is marred by sins of omission and commission alike, and by no means justifies its title—Sainte-Beuve suggested as an alternative, 'Histoire de la race et de la civilisation anglaises par la littérature.' But it was long the best work of the kind done by a foreigner, full of sympathetic insight and subtlety, and admirably written. Taine's greatest work, however, is his study of the Revolution, its causes and its issues, *Les Origines de la France Contemporaine (L'Ancien Régime,*

1875; the Revolution itself, in three sections, 1878-81-85; *Le Règne Moderne*, vol. i. 1890). As a psychological history of the greatest event in modern history this work stands absolutely alone. The first part is a patient and accurate study of the social state of France for a hundred years, proving the inevitableness of revolution and of its violence alike. The treatment of the Revolution itself is original, and constitutes the strongest attack yet made upon it, the conclusion being much the same as that reached by Burke in his *Reflections*. He cherished as whole-hearted a contempt for the democracy as Carlyle, and, as Lord Acton said, fancied that to show the horrors of the Revolution was a good argument against democracy. His ultimate doctrine was that the wealthy and enlightened should lead the ignorant and those who live from hand to mouth. M. Aulard insisted that though honest, Taine was strongly prejudiced; that his documentary basis was incomplete and inadequate, in spite of his wealth of references; that he was guilty of grave inaccuracies in dealing both with facts and with documents; and that his omissions are as grave as his errors. He failed to realise that there may be two sides to a question, and when inconvenient facts presented themselves, he ignored them or belittled their importance.

See his *Derniers Essais de Critique et d'Histoire* (1895) and his *Carnets de Voyage* (1897); Bourget, *Psychologue Contemporain* (1887); G. Monod, *Les Maîtres d'Histoire* (1895); studies by Marguerite (1894), Girard (1901), Aulard (1907), and Picard (1909); and his *Life and Letters* by his widow (Eng. trans. 1902-8).

T'ai-Pings was the name given by foreigners to the followers of Hung Hsiü-ch'uan (S'eiw-tsenen), who raised the standard of rebellion in China in 1851, the enterprise not being finally suppressed till 1865. Hung was born in 1813 in a poor agricultural village of the district of Hwä, in Canton province. His only chance of rising in the world being by literary distinction, he became a diligent student, but he never succeeded in taking the first degree at the provincial capital. Through his visits to Canton, however, he had obtained a bundle of Christian tracts, and gained, we must believe, some knowledge of foreign missions. Returning home from another disappointing competition in 1837, he fell into a long illness, in which he saw visions, and conceived the idea of changing the religion of the empire, and subverting the ruling Manch'ian dynasty. When he got better he began to disseminate his new views, and could soon boast of two converts. These were like himself teachers of village schools, who by-and-by lost their pupils and came into angry collision with their neighbours. In 1844, in company with the elder of the two converts, Hung went into the adjacent province of Kwang-hsi, where they made many converts, and gathered them into communities which they called 'Churches of God.' Hung began also to give forth arrangements and decrees as revelations communicated to him by 'the Heavenly Father,' and the 'Heavenly Elder Brother.' The Heavenly Father was 'the Great God,' and the Elder Brother was 'our Lord Jesus Christ.' Meanwhile progress of organisation proceeded. A strictly moral conduct and the keeping of the Sabbath were enjoined on the congregations; all idolatrous practices and the use of opium were forbidden; professors of union from leaders of the Great Triad Society, pledged to the restoration of a native Chinese dynasty, were rejected.

After some years of uncertain struggle with the official authorities, the insurgents (for such they were now) took possession of the district city of Yung-an. There they hailed their leader as emperor of the dynasty of T'ai-P'ing (Grand Peace),

and adopted T'ien Kwo (Kingdom of Heaven) as the name of his reign. He was himself also styled T'ien Wang (Heavenly King), and some half a dozen of his oldest and most trusted followers were appointed by him his lieutenants, with the title of Wang (Kings). After being kept for some time in a state of siege in the city by their opponents, on the night of 7th April 1852 they burst forth, scattered their besiegers, and commenced their march to the north. Their number was only a few thousands, and they had no artillery, but full of enthusiasm they pressed on. We can only account for their success by recognising the unpreparedness and supine cowardice of the imperial officers and their troops. They passed from Kwang-hsi into Hsiang, got command of the river Hsiang, and before the end of the year had reached the great Yang-tso River. Launching forth on it, and taking on the way the capitals of Hsi-peï and An-hüi, they encamped before Nanking on the 8th March 1853. Within ten days it had fallen into their power, and every man of the Manch'ian garrison been put to the sword. Their host, grown in the twelve months from under 10,000 probably to more than 100,000, proclaimed the T'ai-P'ing dynasty anew, and swore fealty to the Heavenly King. In a few months a large force was despatched northwards to terminate the contest by the capture of Peking. This expedition did wonders, traversed the two provinces of An-hüi and Ho-nan, then marched west to Shun-shi, from which, turning east again, it penetrated into Chih-li, and finally occupied an entrenched position only about 20 miles from T'ian-tsin. But the rebellion had there reached the limit of its advance. Though the expedition met with no great defeat, sufficient reinforcements did not reach them, and the leaders were obliged to retreat towards Nanking in 1855.

From this time the rebel cause began to decay. The moral enthusiasm which had distinguished it in Kwang-hsi disappeared. Dissensions arose between the kings, who strove and fought among themselves, and passed from the stage one after another. Hung created new kings to supply their places, but his name had ceased to be a word to conjure with. He secluded himself from public view, and was unable to institute any system of good order or administration in the extensive provinces subject to his control. The promise of Christian institutions died away. The imperial government, moreover, rallied its forces, and a desperate struggle ensued between them and the rebels. Some of the new kings proved to be men of great ability. Sü-chün and Nang-chün, the capitals of Chiang-sü and Chih-chiang, were both reduced and held by them for a time. How the struggle would have ended was still uncertain, when the imperialists began to call in the assistance of foreigners. A body of men of different nationalities entered their service under an American adventurer known to us from his taking this command as General Ward. He was a very capable man, and did the imperialists good service till he was killed in 1862. Then the British authorities at Shanghai were prevailed on to organise a more effective force, and to put the whole auxiliary movement under the direction of Colonel Charles ('Chinese') Gordon (q.v.). The T'ai-Pings fought with the courage of despair, but they could not long protract the final issue. Nanking was invested by the imperialists, and taken at last on the 19th July 1864. Hung himself, it is supposed, had taken poison a few weeks before, and so escaped capture. His son, a lad of sixteen years, fled under the protection of two of the kings, but they were all three soon taken and executed. What remnants there were of the fighting men made for the south in different bodies, but they gradually melted away,

and were finally extinguished in Canton province in the following year.

Wilson, *Gordon's Chinese Campaign and the Tai-Ping Rebellion* (1868); Wells Williams, *The Middle Kingdom* (1883); A. Egmout Hake, *Events of the Taiping Rebellion* (1892).

Tairen. See DAIREN.

Tait, ARCHIBALD CAMPBELL, Archbishop of Canterbury, was born at Edinburgh, 22d December 1811, and was educated at the Edinburgh Academy and Glasgow University, whence he passed as a Snell exhibitioner to Balliol College, Oxford. In due time he became fellow and tutor, and was one of the four tutors who in 1841 protested against Newman's Tract 90. In 1842 he was appointed successor to Dr Arnold as head-master of Rugby, in 1849 became Dean of Carlisle (where he lost five little girls at once by scarlet fever), and in 1856 Bishop of London, as successor to Blomfield. Here he did much to bring the teaching of the church home to the people, instituting evening sermons in St. Paul's, and encouraging open-air preaching; whilst the 'Bishop of London's Fund' for building schools, churches, and parsonages attained by his efforts to the amount of £350,000. A friend of compromise, though a foe to needless innovations, he showed much tact and personal kindness in dealing with various controversies as to vestments and confession; condemned the *Essays and Reviews*, but promoted moderate measures; and though strongly hostile to Colenso's views, intervened to secure him fair-play. The same love of the *via media*, which caused him now to be accused of bigotry and now of indifference, he manifested when (having declined the Archbishopric of York in 1862) he was in 1868 made Primate of all England by Disraeli. He assisted in composing the statutes raised by the question of Irish disestablishment, but was less successful with the Public Worship Regulation Act and the Burials Bill. He took a keen interest in missions, and greatly helped to extend and improve the organisation of the church in the colonies. The Lambeth Conference of 1878 took place under his auspices. He lost in 1878 both his only son, the Rev. Craufurd Tait, and his wife, a daughter of Archdeacon Spooner, whom he had married in 1843; and he himself died 3d December 1882.

See the *Life* by his son-in-law (Archbishop Davidson) and Canon Benham (2 vols. 1891), and the *Memoir of Catharine and Craufurd Tait* by Benham (1879).

Tait, PETER GUTHRIE, natural philosopher and mathematician, was born at Dalkeith, 28th April 1831. He was educated at the Edinburgh Academy, at Edinburgh University under Professors Kelland and Forbes, and at St Peter's College, Cambridge. He was senior wrangler and first Smith's prizeman of 1852. In 1854 he was elected professor of Mathematics in Queen's College, Belfast, and in 1860 professor of Natural Philosophy in Edinburgh University. While in Belfast he assisted Dr Andrews in experimental researches into the nature of ozone. Subsequently he was associated with Balfour Stewart in experiments on the heating of a disk rotating in vacuo. His most important experimental work was on thermo-electricity, on the pressure errors of the *Challenger* thermometers, on the effect of pressure on the maximum density point of water, on thermal conductivity, and on impact. To mathematical physics he contributed valuable memoirs on *Mirage*, on the *Kinetic Theory of Gases*, as well as many involving quaternionic treatment—all published in the *Transactions of the Royal Society of Edinburgh*, of which Tait was

general secretary from 1879. In pure mathematics his papers on *Knots* and on *Quaternions* are best known; his *Elementary Treatise on Quaternions* (q.v.) proclaimed him the successor of Hamilton. The *Dynamics of a Particle*, by Tait and Steele (1856), became a standard text-book. With Sir W. Thomson (Lord Kelvin) Tait wrote the famous *Treatise on Natural Philosophy* (vol. i. 1867; new ed. in two parts, 1879). The *Unseen Universe*, by Stewart and Tait, and its sequel, *Paradoxical Philosophy*, interested other than scientific minds. Tait also took part in preparing the biographies of Forbes, Rankine, and Andrews. Other writings were *Lectures on some Recent Advances in Physical Science* (3d ed. 1885) and his text-books on *Light* (2d ed. 1889), *Heat* (2d ed. 1892), and *Properties of Matter* (new ed. 1907); and two volumes of his *Scientific Papers* were published in 1898 and 1900. A tractate upon *Newton and the Laws of Motion* appeared in 1899. Having resigned his professorship in the spring of 1901, he died 4th July. See Professor Cargill G. Knott's *Life and Scientific Work of Peter Guthrie Tait* (1911).—His son, Lieutenant FRED G. TAIT (1870–1900), the famous golfer, was shot in a reconnaissance near Koodoosberg in South Africa. A *Life* of him was published in 1910.

Tai-wan, an alternative name for the island of FORMOSA (q.v.). See TAINAN.

Tajiks, a brachycephalic ('Alpine') Iranian people of Persia and Turkestan. See PERSIA (*Inhabitants*), TURKESTAN.

Taj Mahal. See AGRA.

Tajurra Bay, an inlet of the Gulf of Aden into the African coast, on which is the small town of Tajurra. Around it lies the French Somali Coast Protectorate.

Takin (*Budorca taxicolor*), a hollow-horned ruminant, seen but very rarely on the borders of Tibet and Assam, resembling a gnu, but smaller.

Takla Makan, the central Asian desert between the Kuenlun and the Taim. See ASIA.

Takow, a port in SW. Formosa. Its harbour facilities are rapidly being extended, and there is considerable traffic in sugar; pop. 40,000.

Taku, a fortress defending the mouth of the Pei-ho.

Talavera de la Reina, a picturesque town of Spain, on the Tagus, 75 miles S.E. of Madrid. Here, on July 27–28, 1809, Sir Arthur Wellesley, with 19,000 men and 34,000 useless Spaniards, defeated 50,000 veteran French troops under Joseph Bonaparte and Marshals Jourdan and Victor. Pop. 13,500.

Talayots, the name given to the numerous prehistoric stone mounds, 26 to 30 feet in height, found on the island of Minorca. They differ from the Nuraghi (q.v.) of Sardinia and the Brochs (q.v.) of Scotland in having—with very few exceptions—no internal chamber. In origin talayots are perhaps connected with the burial of the dead.

Talbot, a kind of dog deriving its name from the family of Talbot, who had a dog in their coat of arms. The talbot seems to have been the same as that called the St. Hubert's breed, the oldest of the slow-hounds and perhaps the original stock of the Bloodhound (q.v.).

Talbot, a historic English family, traces its descent from Richard de Talbot, named in *Domesday*, whose descendant, Richard, was made a baron (died 1306). The sixth baron, Sir John Talbot, Lord-lieutenant of Ireland, was the famous champion of English arms in France during Henry VI.'s reign, and is familiar to readers of Shakespeare. The hero of some forty victories, he was checked at Orleans by Joan of Arc, and routed and taken prisoner at Patay (1429). Created Earl of

Shrewsbury (1442), he fell fighting against France in the eightieth year of his age (1453). Some of his successors are dealt with at SHEFFIELD. The twelfth earl held prominent office under William III., Anne, and George I., as Lord-lieutenant of Ireland, and Lord High Treasurer and Lord Chamberlain of Great Britain. He was made Duke of Shrewsbury in 1694; but the dukedom died with him (1718). The senior male line of earls died out in 1856, and, after a disputed succession, the title passed to Henry John Chetwynd, third Earl Talbot, who became eighteenth Earl of Shrewsbury. The Lords Talbot de Malahide are a distinct house, and represent a family settled in Ireland in the days of Henry II.

Talbot, WILLIAM HENRY FOX, celebrated in connection with photography, was born at Lacock Abbey, near Chippenham, on 11th February 1800. He passed from Harrow to Trinity College, Cambridge, where he graduated as twelfth wrangler and obtained the junior Chancellor's Medal in 1821. In the first reformed parliament Talbot sat for Chippenham; but scientific investigation being more to his taste, he gave up politics and devoted himself to the problem of fixing shadows. His principal services to photographic art, which in 1842 secured him a Royal Society medal, are described at PHOTOGRAPHY. Others lay in photographic and 'photoglyphic' engraving. Latterly he devoted himself to the study of general physics and to philological and miscellaneous researches, and was one of the first decipherers of the cuneiform inscriptions from Nineveh. He died at Lacock Abbey, 17th September 1877. His *Pencil of Nature* (1846), one of the first works illustrated by photographs, describes his great invention. Amongst his works are *Hermes, or Classical and Antiquarian Researches* (1838-39); *Legendary Tales* (1839); *Antiquity of the Book of Genesis* (1839); and a work on *English Etymologies* (1846).

Talc, a mineral composed almost entirely of silicate of magnesium, in the proportions of 63.5 silica and 31.7 magnesia, with 4.8 water. Its colours are silvery-white, greenish-white, and green. It has a pearly or semi-metallic lustre, and is unctuous to the touch, in which it differs from mica. It cleaves easily into thin flakes which are transparent and flexible, but not elastic. Its hardness = 1, hence it is readily scratched with the finger nail. It usually occurs compact and not in good crystalline forms, but belongs either to the rhombic or the monoclinic system. It is also found massive, in beds associated with mica-schists, gneiss, and serpentine. Talc frequently occurs in rocks as an alteration-product, especially of magnesia minerals that contain little or no alumina. Hence it frequently replaces enstatite, augite, hornblende, &c. It is found in Scotland, Tyrol, the Pyrenees, and various parts of the United States, and is or has been used like Mica (q.v.) for stoves and ovens, for slate-pencils, for surfaces exposed to acids, for stoppers of chemical bottles, &c.—A kind called *Indurated Talc*, or *Talc Slate*, has a curved slaty structure, and is not separable into laminae like common talc. It approaches in character to Steatite (q.v.), and is used for similar purposes.

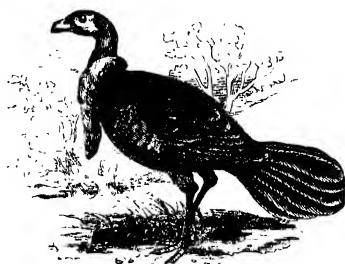

Talca, a town of Chile, on the Claro River, capital of the province of the same name (pop. 131,000), manufactures woollens, and trades in wines, wheat, &c.; pop. 36,000.

Talcahuano, the port of Concepción (q.v.) and principal naval base of Chile; pop. 22,000.

Tálchir Beds, a group of strata occurring at the base of the Gondwana series of India. They probably occupy the same geological horizon as the Upper Carboniferous of Europe, but owing to

the rarity or absence of marine fossils their exact correlation with their European equivalents is somewhat uncertain. The beds are remarkable for the occurrence in them of numerous small and large erratics, some of the latter measuring 15 feet in diameter. In the neighbourhood of the Godavari the included blocks of foreign and transported rocks are smoothed, polished, and striated in the same manner as glaciated stones. Moreover, the hard Vindhyan limestone which underlies this Tálchir boulder-bed is similarly smoothed and scored in long parallel lines.

Talegalla, or **BRUSH TURKEY**, a name given to several Australasian gallinaceous birds in the same family (Megapodidae) as the Mound-builders. One of the best known is the Bush Turkey (*Cathartes lathami*) of eastern Australia, a blackish-brown bird, with pink head and neck, and a bright yellow neck-wattle. It is nearly the size of a female turkey. It frequents thickly wooded parts, and escapes from dingoes and other enemies by taking refuge in the brush or by ascending trees. It is easily shot. These 'Talegallas' are often seen in small flocks, and they make their mounds together. A mound may be 6 feet high and 14 feet in diameter at the base, and is formed by kicking earth and decayed vegetation backwards. Several females may use the same mound, and the cocks probably assist in the construction. The same mound may be used for several years. In a cup-shaped hollow in the centre the eggs (20 to nearly 40) are placed, small end downwards, in circles and in layers. The heat of the fermenting vegetation favours development; the young bird may leave

Brush Turkey (*Cathartes lathami*).

the mound twenty-four hours after hatching. The bird has bred in the Zoological Gardens in London, and might perhaps be domesticated for the sake of its palatable flesh and eggs. Nearly related are various species of Talegallus, whose mounds may be 11 feet high and show an internal temperature of 93° Fahr. See MOUND-BIRDS.

Talent (Gr. *talanton*, from a root 'to balance or weigh') was the heaviest unit of weight among the Greeks. The word is used by Homer to signify indifferently a balance and a definite weight of some monetary currency. Silver coin was first struck in Hellas proper in the island of Ægina, and the Æginetan standard was apparently adapted to the Babylonian gold standard. The Babylonian commercial talent seems to have been either 65 lb. 5 oz. or 66 lb. 5½ oz. Derivatives of this (containing 3000 shekels) were in use in Phœnicia and Palestine; but there was another silver talent, and a gold talent worth 2½ of the commercial talent. The Euboic talent was of smaller monetary measure and weight than the Æginetan. Its use was mostly confined to Athens, Chalcis, and

the Chalcidian colonies; while the Æginetan prevailed over the rest of the Greek world. About the middle of the 6th century B.C. the Attic standard arose, and it is impossible henceforth to distinguish the history of the Euboic from that of the Attic talent. These several talents were similarly subdivided into 60 minæ, the minæ (Gr. *μνα*) into 100 drachmæ, and the drachma into 6 oboli; and their relative proportions are Æginetan talent: Euboic talent: Attic talent :: 39:26:27, the weight of the first being 83½ lb. avoird., of the second 55½ lb., and of the third 57½ lb. Besides the Attic talent there were other talents in use at Athens for weighing various articles. One of these was the Commercial or Æmporic, which was identical with the Æginetan standard for coins and corresponded in use to our weight avoirdupois, being the ordinary weight in use in the market.

Talfourd, SIR THOMAS NOON, was born at Reading, 26th May 1795. The son of a Reading brewer, he was educated at the grammar-school there under Dr Valpy, and in 1821 was called to the bar at the Middle Temple. He became a serjeant-at-law (1833), Whig member for Reading (1835-41 and 1847-49), and a justice of Common Pleas (1849), at the same time being knighted. He died of apoplexy during Stafford assizes, 13th March 1854. Talfourd is remembered by his four nearly forgotten tragedies, of which *Ion* (1835) was brought out by Macready at Covent Garden; by his Copyright Act (see COPYRIGHT) of 1842; and by his writings on Charles Lamb.

Taliacotius. See RHINOPLASTIC OPERATIONS.

Ta-lien-wan. See DAIREN.

Taliesin, or TALIessin, a 6th-century Welsh bard, perhaps wholly mythical, to whom much poetry of later periods, preserved in the 14th-century *Book of Taliesin*, has been attributed.

Talio. See CRIMINAL LAW.

Talipot, **Talipot**. See PALM.

Talisman (though Spanish from Arabic, from the Gr. *telesma*, 'mystery,' 'initiation'), a species of charm, consisting of a figure engraved on metal or stone when two planets are in conjunction, or when a star is at its culminating point, and supposed to exert some protective influence over the wearer of it. The terms *Talisman* and *Amulet* (q.v.) are often considered nearly synonymous, but the proper distinctive peculiarity of the former is its astrological character. Talismanic virtues have often been attributed to a peculiarly marked or formed egg, and instances are recorded, by various authors, of eggs hatched with figures of comets or eclipses on them. Talismans which acquired considerable celebrity were the Abraxas Stones (q.v.). Another historic talisman is the Lee-penny, a heart-shaped, dark red jewel, now set in a shilling of Edward I., with a silver chain and ring attached, supposed to have been obtained in Spain by Sir Simon Lockhart, who set out with Sir James Douglas to bear Bruce's heart to the Holy Land. So late as 1824 water in which it had been dipped was used to cure cattle bitten by a mad dog. A species of talisman at present in use in Asia is a piece of paper on which the names of the Seven Sleepers and their dog Kitmer are inscribed. Pasted on the walls of houses, it is believed to be a protection against ghosts and demons. The Phylactery (q.v.) was a common talisman; and in Christian Byzantium phylacteries were made bearing the figure of Solomon, the compeller of demons. See ABRACADABRA, ASTROLOGY, DIVINATION, EDENHALL, EVIL EYE, INCANTATION.

Tallage, a tax to which, under the Anglo-Norman kings, the demesne lands of the crown and all royal towns were subject.

Tallahassee, the capital of Florida, 166 miles by rail W. of Jacksonville, has a capitol and several colleges; it has wagon and canning industries, and is the centre of an agricultural district, in which the vine is largely cultivated; pop. 6400.

Tallart, or TALLARD, CAMILLE, COMTE DE (1652-1728), served with distinction in the wars from 1670 on, under Condé and Turenne, commanded a corps d'armée in the War of the Spanish Succession, and, a marshal of France, was defeated by Marlborough at Blenheim (q.v.).

Tallemant des Réaux, GEDÉON (1619-92), the Brantôme of his century, was born at La Rochelle, studied law, and married his cousin Elisabeth Rambouillet, daughter of a wealthy farmer of revenues; and having bought the seigniorial estate of Plessis-Rideau in Touraine, changed its name to Des Réaux. His famous work, the *Historiettes*, written in 1657-59, is invaluable as a complete picture of the society of his time; the most finished group of these portraits in miniature, that of the famous circle of the Hôtel de Rambouillet, without doubt coloured the style and tone of Tallemant. He takes a malignant pleasure in setting forth the vices of the great, and shows a relish for a scandalous story. His short characters, as printed by Monmerqué, are 376 in number, in no case finished biographies, rather collections of illustrative anecdotes, throwing strong light from behind the scenes on the leading figures of three-quarters of a century. And still more, those portraits may generally be accepted as sound and truthful, if some allowance is made for the natural maliciousness and personal prejudices of the writer.—His brother, the Abbé Tallemant (1620-93), was a man of wit and an academician, but his *Vies de Plutarque* (1663) brought him little credit.—His cousin, Paul Tallemant (1642-1712), early began to scribble verses, at eighteen wrote his *Voyage de l'Île d'Amour*, an ingenious commentary on Mlle. de Scudéry's famous 'Carte de Tendre,' and entered the Academy in 1666.

The *Historiettes* of Tallemant des Réaux were first published, from the MSS. of the author, by Monmerqué, de Châteaugiron, and Taschereau (1834); a second edition was by Monmerqué (1840); and a third by Paulin Paris (1872). See Life by Magne (1921-22).

Talleyrand de Périgord, CHARLES MAURICE, Prince de Bénévent, the most inscrutable and resolutely self-regarding of modern politicians, was born at Paris on 2d February 1754. His father, Charles Daniel, Comte Talleyrand de Périgord (1734-88), was an officer in the army of Louis XV. during the Seven Years' War. An accident early in life, followed by an act of legal injustice, seems to have had a determining influence—for evil and not for good—on Talleyrand's character and career. By this accident he was lamed for life, and, in consequence, his rights of primogeniture were transferred to a younger brother, while he himself was, to his regret, educated not for the army but for the church. He threw himself, however, at the Collège d'Harcourt, at the Séminaire de St Sulpice, and at the Sorbonne, which he subsequently attended in succession, into the work of gratifying his ambition. He made himself a fair scholar, and cultivated the character of a rake and a cynical wit. His promotion, considering his well-known immorality, was rapid. He obtained the abbacy of St Denis in 1775, and five years later he was appointed *agent-général* to the French clergy; finally, Louis XVI. appointed him Bishop of Autun in 1789. Meanwhile he had been watching the signs of the times in France, and carefully studying politics. In 1789 the clergy of his diocese elected him to represent them in the States-general; and on this occasion he delivered a

speech which at once stamped him as a political leader. He now became an authority on constitutional, financial, and educational questions, and the friend of men of such widely different gifts as Mirabeau, Sieyès, and Lally-Tollendal. He was one of the members of Assembly who were selected to draw up the Declaration of Right. He took a cynical delight in attacking the profession to which he still nominally belonged. It was he who in 1789 proposed the measure for the confiscation of the landed property of the church. He had rightly calculated that nothing could make him more popular with the rank and file of the revolutionaries in the Assembly; and on the 13th February was elected its president for the usual period. In November he took the oath to the new constitution, and in the beginning of 1791 he consecrated two new bishops—those of Aisne and Finistère—declaring at the same time his sincere attachment to the holy see. It was now, however, open war between it and Talleyrand. In April he was excommunicated by the pope; he retaliated by giving up the clerical career altogether. About this time he was appointed director of the department of Paris in succession to Mirabeau. His most remarkable achievement, however, as a member of the National Assembly was his preparation of a report upon public instruction. This document was greatly in advance of the times, and was undoubtedly the model followed in all the great changes that subsequently took place, when France reorganised her educational system.

Talleyrand, although a favourite in Paris, had never been in sympathy with the fiercer spirits of the Revolution, and indeed was at heart a believer not in the Republic but in a constitutional monarchy. He was heartily glad, therefore, to leave France for London on an unofficial diplomatic mission early in 1792, and did his best to reconcile Pitt to his country, but failed. In December of the same year his connection with the Revolution was brought to a close by his being placed on the list of *émigrés*. He remained in exile in London till the end of January 1794, when he was compelled to leave under the provisions of the Alien Act. He had made many friends in London, and Lord Lansdowne having given him an introduction to Washington, he sailed for the United States. After the fall of Robespierre the sentence of proscription on him was recalled, and he returned to Paris in 1795. He attached himself to the party of Barras, and in 1797 he was called by the public opinion of the country to the post of foreign minister under the Directory.

Talleyrand was for a time the first man in France, Barras being simply his tool. But he had already recognised the genius of Bonaparte, and established intimate relations with him. For a short period, however, he was in disgrace, the fact having been revealed that he had indicated his willingness to sell his services in connection with the conclusion of a treaty between Great Britain and the United States for money. But on the establishment of the Consulate he was restored to his former position as foreign minister, and for many years was closely associated with the fortunes of Napoleon. He had no genuine love for his master, but simply made him a means towards his own aggrandisement and enrichment. Gambling was his chief pleasure, and laid the foundation for an enormous fortune. Among the more odious of the acts of Napoleon with which Talleyrand will always be associated are the kidnapping and murder (March 1804) of the Duc d'Enghien. It is virtually beyond doubt that it was by his instructions that the crime was consummated in spite of the vehement opposition of Josephine, whose opposition led her to denounce him as a *maudit boiteux*.

He was greatly instrumental in consolidating the power of Napoleon first (1802) as consul for life and then (1804) as emperor. When in the following year Great Britain, dreading a French invasion, formed a powerful European coalition against France, it was by the ingenuity of Talleyrand that it was, partially broken up. To him as much as to Napoleon was owing the organisation in 1806 of the Confederation of the Rhine. Napoleon and he were thoroughly at one as regards the foreign policy of France till the conclusion of the peace of Tilsit in July 1807. After his creation as a prince of the empire under the title of Prince de Bénévent, he withdrew from the Ministry. The failure of Napoleon's designs in Spain was, however, the occasion of the first real rupture between him and Talleyrand.

Although Talleyrand was an advocate of the Austrian marriage, his voice was on the whole for a policy of wisdom during the later years of the first empire. In particular he was opposed to the invasion of Russia; and this gives some justification for his desertion of Napoleon in 1814. That desertion was complete and, from his own point of view, successful. He became the leader of the anti-Napoleonic faction; and through him communications were opened both with the allies and with the Bourbons. He dictated to the Senate the terms of Napoleon's deposition; and he became minister of foreign affairs under Louis XVIII., whom, indeed, he had placed on the throne. In his country's distress Talleyrand was now as much its good genius as was Thiers at a later and even darker period of its history. He negotiated the treaties by which the allies left France in possession of the boundaries which had been established in 1792, and in the congress which met in Vienna in September he successfully vindicated her rights to be heard in the readjustment of European arrangements. He had not calculated on the Hundred Days, however, and offered no help to Louis, who, on Napoleon's escape from Elba, had retired to Ghent. Yet the allied powers insisted on his being taken back into royal favour, and after the second restoration he became prime-minister. He remained in office, though, only for a short time, as he found himself the reverse of a *persona grata* to the king, and disliked by all existing parties in France.

During the reigns of Louis XVIII. and Charles X. Talleyrand was little better than a discontented senator who never lost an opportunity of injuring the court and the government, although it is possible that his protest in 1823 against the Spanish war was animated by genuine regard for his country's interests. During the July revolution he was Louis-Philippe's chief adviser. The citizen king offered him the post of foreign minister, but he declined it. He went to London as ambassador, and was well received there. He reconciled the British ministry and court to France, and returned in triumph to Paris, and finally retired into private life in 1834, and died at Paris on 17th May 1838, at the age of eighty-four.

'A man living in falsehood and on falsehood; yet not what you can call a false man' is Carlyle's view of Talleyrand. 'That rather middling bishop but very eminent knave' is De Quincey's. Both views have been widely entertained; but Talleyrand is a puzzle—more of a puzzle since the publication of his *Memoirs* than he was even before. That he was shamelessly corrupt, immoral, selfish, and mendacious is beyond doubt. Nor was he a wise statesman in the modern sense; the amelioration of human society never entered into his calculations as an object to be aimed at. But he was amazingly clever, infinitely dexterous, and an admirable judge of men, and in his tortuous

diplomacy he generally considered and sought his country's advantage as well as his own.

The Talleyrand *Memoirs*, published in 1891 by the Duc de Broglie, and translated by Mrs A. Hall, are disappointing and unreliable, even if they were not tinkered by Baccourt, Talleyrand's literary executor, or, as Augustin Thierry maintains (*Les Grandes Mystifications*, 1911), written by the Baron de Lamothé-Laigou. For his public career see the works of Mignet, Bastide, and Louis Blanc, the Lamartine, Guizot, and Rovigo *Memoirs*, Sir Henry Lytton Bulwer's *Historical Characters*, Sainte-Beuve's lectures, Pallain's *Correspondence between Talleyrand and Louis XVIII.*, and the Lives by Lacombe (trans. 1910) and Lolive (trans. 1912). Michaud's *Histoire politique et privée* (1853) and Pichot's *Souvenirs Intimes sur M. de Talleyrand* (1870) are partisan pamphlets; McCabe's *Talleyrand* (1906) is also eminently apologetic.

Tallien, JEAN LAMBERT, was born the son of a butler at Paris, 23d January 1767, and was first a lawyer's clerk, next employed in a printing-office, and made himself famous in the first months of 1791 by his Jacobin broad-sheet, *L'Ami des Citoyens*. He was conspicuous in the attack on the Tuileries (10th August), and became secretary to the Commune Insurrectionelle. He had his share in the infamous September massacres, and was elected by Seine-et-Oise to the Convention, where he was one of the most intemperate among the Jacobins, voted for the death of the king, was elected to the Committee of General Security, and played a part in the downfall of the Girondists (June 2). In September he went on his memorable mission to Bordeaux, where he extinguished all opposition under the guillotine, and disgraced himself by shameful profligacy. But a passion for one of his victims, the lovely Comtesse Thérèse de Fontenay (1775-1835), the daughter of the Spanish banker Cabarrus, was said to have changed his nature, and earned for her the title of 'our Lady of Pity.' He was recalled, but in 1794 was chosen president of the Convention. Robespierre hated his insincerity and immorality, and Tallien, recognising his danger, took an active part in the successful attack (really engineered by Fouché) upon the Dictator on the 9th Thermidor. Tallien, now for a moment one of the most influential men in France, lent his aid to suppress the Revolutionary Tribunal and the Jacobin Club, and drew up the accusations against Carrier, Le Lion, and others of the Terrorists; but his importance ended with the Convention, and soon after the frail Thérèse, who had married him in December 1794 and reigned awhile the social queen of Paris, deserted him for a wealthy banker. Bonaparte carried him to Egypt, and for some time he edited the official *Décade égyptienne* at Cairo. On the voyage homeward he was captured by an English cruiser, and brought to England, where the Whig Opposition were stupid enough to make a hero of him (1801). Later he was through Ponché and by Talleyrand sent as consul to Alicante. He died in poverty at Paris, 16th November 1820.

In his *Life of Madame Tallien* (trans. 1913), Gastine has stripped the romance from the story of the 'lion amoureux' and the 'lady of pity,' and proved him a contemptible adventurer and robber, and her a grasping courtesan.

Tallis, THOMAS, 'the father of English cathedral music,' was born about 1510, held the post of organist of Waltham Abbey till the Abbey was dissolved, and after 1540 was attached to the Chapel Royal. In Day's Psalter (1560) there appear eight tunes composed by Tallis, one of these being still used to Ken's evening hymn. In 1575-76 letters patent were granted to Tallis and William Byrd (q.v.) according to them 'the exclusive privilege of printing music and ruled music paper for twenty-one years.' The first work printed under this patent was issued in 1575,

entitled, '*Cantiones quæ ab argumento Sacre vocantur, quinque et sex partium*,' containing sixteen motets by Tallis and eighteen by Byrd. Tallis died on 23d November 1585, and was buried in the chancel of Greenwich parish church, with an epitaph in verse, which was afterwards set to music by Dr Cooke as a glee. Tallis, besides writing a large number of anthems, pieces, responses, and Te Deums (a complete list of which appears in Grove's *Dictionary of Music*), was the author of a celebrated work—'Song of the Forty Parts,' composed for eight choirs of five voices each. Tallis, it has been well said, was 'one of the greatest contrapuntists of the English school. His works are invested with great learning and much dignity, and are highly calculated to impress by their solemnity and power.'

Tallow. See FATS, OILS, LUBRICANTS, MINERAL TALLOW.

Tallow-tree, the name given to trees of different kinds which produce a thick oil or vegetable tallow, or a somewhat resinous substance, which, like tallow, is capable of being used for making candles. The tallow-tree of Malabar (*Valeria indica*) is a very large tree of the family Dipterocarpaceæ (see COPAL). The tallow-tree of China (*Sapum sebiferum* or *Stillingia sebifera*) belongs to the family Euphorbiaceæ. It has been naturalised in India, the West Indies, and in some parts of the southern United States. The capsules are internally divided into three cells, each containing a nearly hemispherical seed, which is covered with a beautifully white vegetable tallow. For the manufacture of candles the capsules and seeds are crushed and boiled, and the fat skimmed off in a melted state. To improve the consistency, wax or linseed-oil is added. The leaves are used in dyeing. The tallow-tree or butter-tree of West Africa (*Pentadesma butyrafra*) is of the Guttifera. The name tallow-tree is sometimes given in North America to a species of Candleberry (q.v.).

Tally (Fr. *tallier*, 'to cut'), the name given to the notched sticks which, till the beginning of the 19th century, were used in England for keeping accounts in Exchequer, answering the double purpose of receipts and public records. They were well-seasoned rods of hazel or willow, inscribed on one side with notches indicating the sum for which the tally was an acknowledgment, and on two opposite sides with the same sum in Roman characters, along with the name of the payer and the date of the transaction. Different kinds of notches, differing in breadth, stood for a penny, a shilling, a pound, £20, £100, £1000. The tally was cleft through the middle by the deputy-chamberlain with knife and mallet, so that each piece contained one of the written sides, and a half of every notch; and one half was retained by the payer as his receipt, while the other was preserved in Exchequer. At the union of England and Scotland a store of hazel rods for tallies was sent to Edinburgh, but never made use of. An act of George III. (1783) decreed the discontinuance of tallies in Exchequer, but some use was made of them till 1812; the old tallies were ordered to be destroyed in 1834; and the overheating of the stove within the precincts of the House of Lords in which the tallies were burned caused the conflagration in which the old Houses of Parliament were destroyed.

Tally System is the name given to a mode of dealing by which dealers furnish certain articles on credit to their customers upon an agreement for the payment of the stipulated price by certain weekly or monthly instalments. This petty credit system of dealing is carried on chiefly in London and other large towns, in stores or shops known as tally-shops. Both seller and purchaser keep

books in which the circumstances of the transaction and the payment of the several instalments are entered, and which serve as a tally and counter-tally. The prices charged under this system are usually exorbitant, and the goods sold, which principally consist of wearing apparel and cheap finery, furniture, hardware, and other household goods, are generally very inferior in quality.

Talma, FRANÇOIS JOSEPH, an eminent French tragedian, was the son of a dentist, and was born at Paris, 15th January 1763. He made a creditable début in 1787 at the Comédie Française as *Séide* in *Mahomet*, but the occasion of his first great success was his innovation in costume when playing Proculus in the tragedy of *Brutus*. Previously actors had worn the garb of their own country and even their own time. Talma appeared in a Roman toga. 'Look at Talma,' said a member of the company; 'how ridiculous he is! He has quite the air of an ancient statue!' a compliment as exquisite as it was unintentional. Henceforth Talma, aided by the counsels of the painter David, made a point of rigorous accuracy in costume; and his own remarkably handsome figure, fine voice, and perfect elocution, together with that matchless ease of movement which came after much labour, combined to fit him for the highest tragic rôles. But it was not till 4th November 1789, when he played Charles IX. in Clénier's play, that he rose to his full height in popular estimation. In 1791 he quarrelled with his associates, and with some other dissentients founded the Théâtre Français de la rue de Richelieu—the name changed next year to Théâtre de la République. Here he reigned throughout the Revolution in such characters as Othello; Nero in *Epicharis et Néron*; and Agasthenes in *Agamemnon*. Some of his later characters were among his best; Leicester in *Marie Stuart*; Sylla; Orestes; Leonidas; and Charles VI. Talma died 19th October 1826. See *Memoires sur Talma*, by Moreau (1826), and his Autobiography, edited by A. Dumas (4 vols. 1849-50).

Talmage, THOMAS DE WITT, pulpit orator, was born at Bound Brook, New Jersey, 7th January 1832, and after holding several charges, from 1869 to 1894 he was pastor of an important Presbyterian church in Brooklyn. He died 13th April 1902. His sermons were translated into many tongues; and a long series of them were issued under fantastic titles.

Talmud (from Heb. *lamad*, 'to learn'; i.e. 'The Study') is the name of the fundamental code of the Jewish civil and canonical law, comprising the Mishna and the Gemara, the former as the text, the latter as the commentary and complement. This 'Oral' or Post-mosaic Code was of gradual development; it is generally recognised that there were older collections upon which the Mishna was framed before being finally redacted in the form in which we now possess it. The oldest codification of *Halachoth*, or single ordinances, is due to the school of Hillel (q.v.). Simon, son of Gamaliel II. and great-grandson of Gamaliel I., mentioned in the New Testament, and his school carefully sifted the material thus brought together. He died 166 A.D. His son Jehudah Hannasi, commonly called Rabbi, who died 219, and his disciples worked the work to its close in six portions (*Sedarim*), 63 treatises (*Masichtoth*), and 524 chapters (*Perakim*), which contain the single Mishnas. But besides this authoritatively compiled code there were a number of other law collections, partly anterior to it, and not fully embodied in it, partly arising out of it—as supplements, complements, bylaws, and the like—partly portions of the ancient Midrash, partly either private textbooks composed by the masters of the academies

for their lectures or enlargements of the existing Mishna. All this additional legal material was collected, not rarely together with the discussions which begot it, under the name of *Baraitoth*, 'foreign,' 'external,' by Chaiya and his school, in the succeeding generation. Not to be confounded with them, however, are the collections of *Toseftas* 'supplements,' or *Great Mishnas*, which, commenced at the time of Jehudah Hannasi himself, and continued after his death by his scholar Chaiya and Hoshaiya, embody much of what has been purposely left out in the concise Mishna, which only embraced the final dicta and decisions. Such 'additions' we possess now to 52 treatises, forming together 383 *Perakim* or chapters. All these different sources of the 'Oral Law'—finally redacted before the end of the 3d century, though probably not committed to writing until 550 A.D.—belong to the period of from about 30 B.C. to about 250 A.D. This great mass of legal matter, although apparently calculated to provide for every case, if not for all times, was yet found insufficient. The dicta of later masters, the decisions of the courts, the discussions on the meaning and purport of special traditions, the attempts at reconciling apparent contradictions in the received material, the amplifications or modifications of certain injunctions rendered necessary by the shifting wants and conditions of the commonwealth—all these and a number of other circumstances made a further codification preperatory.

We must not omit to state here that this Mishna (*Mathnithin*), although it contained nothing but what were indigenous laws and institutions, was yet not a little influenced—if the very fact of its redaction was not indeed caused—by the spirit of the times. At Berytus, at Alexandria, at Rome the legal schools were then in their most vigorous stage of development, and everywhere system and method were being introduced into what till then had been a vast complex of traditional and popular institutions, decrees, and decisions. The Mishna in all respects fulfilled the conditions reasonably to be demanded from such a text-book as it was intended to form; it was clear, concise, complete, and systematic, and moreover composed in as classical a Hebrew as still could be written in those days of decadence of the 'sacred language.'

The further development of this supplementary, oral, or second law—in fact rather an exegesis thereof—together with the discussions raised by apparent contradictions found in the individual enactments of the Mosaic doctors, is called Gemara—i.e. Discussion, Complement, or, according to another explanation, Doctrine. This Gemara contains, apart from the *Halacha*, which is generally written in Aramaic, also a vast number of non-legal, chiefly Hebrew, fragments—homiletic matter, tales, legends, and the like—called *Haggada*.

There are two Talmuds, the one called the Talmud of the Occidentals, or the 'Jerusalem' (Palestine) Talmud, which was closed at Tiberias, and the other the 'Babylonian' Talmud. The first of these now extends over thirty-nine treatises of the Mishna only, although it once existed to the whole of the first five *Sedarim* or portions. It originated in Tiberias in the school of Johanan, who died 279 A.D. Its final redaction probably belongs to the end of the 4th century; but the individual academies and masters through whom it received its completion cannot now be fixed with any degree of certainty. There is less discussion and more precision of expression in this than in the second or Babylonian Talmud, emphatically styled 'our Talmud,' which was not completed until the end of the 5th century, and which makes use of the former. As the real editor of the Baby-

lonian Talmud is to be considered Rabbi Ashe, president of the academy of Sora in Babylonia (352-427 A.D.). Both the Mishna and the Palestine Gemara had, notwithstanding the brief period that had elapsed since their redaction, suffered greatly, partly by corruptions that had crept into their (unwritten) text through faulty traditions, partly through the new decisions arrived at independently in the different younger schools—of which there flourished many in different parts of the Dispersion—and which were at times contradictory to those arrived at under different circumstances in former academies. To put an end to these disputes and the general confusion arising out of them, which threatened to end in sheer chaos, Rabbi Ashe, aided by his disciple and friend Abina or Rabina I. (abbr. from Rab Abina), commenced the cyclopean task of collecting anew the enormous mass of Halachistic material which by that time had grown up. The method he pursued was simple enough. His disciples met twice a year at Sora, in spring and in autumn. At the spring gathering he gave out all the paragraphs of one treatise; and the disciples had the task to find out until the autumn meeting what opinions the different schools had pronounced on the special points thereof. He then investigated the whole critically, and put it into shape according to a certain order. This process took him, with the assistance of ten secretaries, no less than thirty years; and many years were spent by him in the revision of the work, with which he proceeded in the same manner as he had done with the compilation itself. The final close of the work, however, is greatly due to Rab Abina II., head of the Sora academy (473-499). He was the last of the Amoraim expounders, who used merely oral tradition. After them came the *Saboraim*, the reflecting, examining, critical, the real completers of the Babylonian Talmud, and by many in ancient and modern times declared to have first reduced Mishna and Talmud to writing.

The Babylonian Talmud, as now extant, comprises the Gemara to almost all tractates of *Sederim* II.-V. There is also Gemara to the first treatise of the first, and to the first of the last order. The rest, if it ever existed, which is very doubtful, is now lost. The whole work is about four times as large as the Jerusalem one, and its thirty-six treatises, with the commentaries generally added to them in our editions (*Rashi* and *Tosafot*), fill 2947 folio leaves. The language of the Talmud is, as we said, Aramaic (Western and Eastern), closely approaching to Syriac. The minor idiomatic differences between the two are easily accounted for by differences of time and place; but the additional matter—quotations and fragments from older Midrash and Gemara collections, *Haggada*, &c.—is, as before stated, principally written in Hebrew.

The masters of the Mishna (*Tannaim*) and of the Gemara (*Amoraim*) were followed by the *Saboraim* (see above). The code of the oral law had come to a close with the second named; and not its development, but rather its proper study, elucidation, and carrying into practice was the task of the generations of the learned that followed. Apart from this, the Aramaic language itself began to die out as the popular language, and required a further study. The *Saboraim* no longer dared to contradict, but only opined on the meaning and practicability of certain enactments, and undertook the task of inculcating and popularising the teachings laid down by their sires; apart from bestowing proper care upon the purity of the text itself, and adding some indispensable glosses. Their activity was at its height in the 8th century, when Karaism (see *Jews: Religion*), which utterly denied the authority of the Talmud, sprang

into existence. Respecting, however, this authority of the Talmud itself, there has never been anything approaching to a canonicity of the code, or to a reception of it as a binding law-book by the whole nation. The great consideration in which it was always held is owing partly to its intrinsic value, and to the fact of its becoming the basis of all further development of Jewish literature (it being undeniably the most trustworthy receptacle of the traditional Jewish law), and partly to the persecution of the Jews in the Persian empire at the time of Yazdigerd II., Firuz, and Kobad I. (438-531), who closed the schools and academies for a space of nearly eighty years, during which this book was the sole authoritative guide of public conscience, and remained endowed with its importance even when the schools were restored. The best commentaries of the Mishna are by Maimonides and Bartenora; of the Babylonian Talmud by Rashi (q.v.) and the Tosafists of France and Germany. An abstract of the Talmud for practical legal purposes by Maimonides (q.v.) is called *Mishneh Torah*. The Mishna was first printed at Naples, 1492; the Talmud of Jerusalem at Venice, by D. Bomberg, 1523. The entire Babylonian Talmud was first published at Venice by him in 1520. Previously Gershom Soncino had printed twenty-three separate treatises (1488-1519) at Pesaro and Soncino. It is generally printed in twelve folios, the text on the single pages being kept uniform with the previous editions, to facilitate the references. For translations of the Gemara see the bibliography below. The complete Mishna has been translated repeatedly into Latin, German, Spanish, &c., by Surenhusius, Rabe, Jost, and others. We must refrain in this place from attempting a general characterisation of the Talmud, a work completely *sui generis*, which is assuredly one of the most important records of humanity. Nothing can give even an approximate idea of the immensity of material, historical, geographical, philological, poetical, that lies hidden in its mounds. A contribution to the records of fanaticism may also be found in the 'exoteric' history of the Talmud, which was, albeit utterly unknown save by a few garbled extracts, prohibited, confiscated, burned, and generally prosecuted and inveighed against by emperors, popes, theologians, and fanatics generally, from Justinian down almost to our own day, as perhaps no other book has ever been. In our own times, however, its value begins to be recognised by great scholars, not merely as the only source of the knowledge of Judaism, but as the chief source—next to the gospels—even for the history of the origin and early days of Christianity; a notion long ago hinted at by eminent divines like Lightfoot and others.

See also *Jews*, *MISHNA*, *EXEGESIS*, and an essay in the *Literary Remains of Ein Deutscher*, original author of the above article. Moïse Schwab has translated the Jerusalem Talmud into French (Paris, 1871; retranslated into English). The Babylonian Talmud has been translated or adapted by J. M. Rabinowicz in his *Legislation Criminelle du Talmud* (Paris, 1871), and *Legislation Civile du Talmud* (5 vols. Paris, 1877); Aug. Wünsche, *Der Jer. Thalmud in seinen haggadischen Bestandtheilen ins Deutsch übers.* (Zurich, 1880), and *Der Bab. Thalmud in seinen haggadischen Bestandtheilen* (Leip. 1886); N. Brüll, *Die Entstehungsgeschichte d. Bab. Thalmud, in Jahrbücher f. Jüd. Gesch. u. Lit.* II. (1876); Z. Frankel, *Introductio in Thalmud Hierosol.* (Breslau, 1870); W. Bacher, *Die Agada d. Palästinensischen Amoräer* (Strasb. 1892); Jastrow, *Dictionary of the Targumim and the Talmud* (Lond. 1887-92); J. Levy, *Neuhebr. . . Wörterb., . . u. d. Talm.* . . . (Leipzig, 1876). A supplement was issued by L. Goldschmidt (Berlin, 1924). The recent anastatic reprints of Levy and Jastrow are, in many cases, hard to read. The student is advised to obtain the old editions. M. L. Rodkinson's abridged English trans. (New York, 1896-) is not so useful as

the German version (with critical text and notes) of L. Goldschmidt (Berlin, 1897-). A number of separate tracts have been translated (see p. 301 of S. Levy's *Jewish Year Book* Lond. 1927). J. H. Lowe's *Tutorial Preparation* (Lond. 1926) is for self-instruction.

The following articles and bibliographies are of great importance: W. Baehrer (*Jew. Ency.*, xi. 1); M. Riehtman (*ib.* 27); J. Z. Lauterbach (*ib.* 30); L. Blau (*ib.* 33); S. A. Cook (*Ency. Brit.*, xxvi. 380); I. Abrahams (Hastings's *E.R.A.*, xii. 185: this article is of great value for its appraisal of the Talmud as a factor in life); 'Permanent value of the Talm.' in his *Permanent Values* (Oxf. 1924, p. 67); ch. iii. in his *Short Hist. of Jew. Lit.* (Lond. 1906; see also select bibliography on p. 27); S. Schechter (Hastings's *Dict. Bible*, 1904, v. 67); 'Hist. of Jew. Trad.' in his *Studies in Jud.* (Lond. 1896, i. ser. i. 222); 'On the Study of the Talm.' (Philad. 1908, *ib.* ser. ii. 102); P. Fiebig (*Relig. in Gesch. u. Gegenwart* Tüb. 1913, iv. 388); H. L. Strack (*New Schaff-Herzog* New York, 1903, xi. 255); F. Schullein (*Cath. Ency.*, xiv. 435; various printer's errors).

The following introductions may be noted: H. L. Strack, *Einführung in d. Talm.* (Leipzig, 1894, and later editions); M. Mielziner, *Introduct. to the Talm.* (New York, 1925); S. Funk, *D. Entstehung d. Talm.* (Leipzig, 1910); M. Braunschweiger, *D. Lehrer d. Mischnah* (Frankfort on the M. 1903).

Talpidæ. See MOLE.

Talus, a term employed in Geology to designate the sloping heap which accumulates at the base of a rock or precipice, from fragments broken off by the weather, or materials in any way carried over it. The term is also applied to the slope of a wall which diminishes in thickness as it rises.

Tamaqua, a borough of Pennsylvania, on the Tamaqua or Little Schuylkill River, 134 miles by rail W. of New York. It has an extensive coal-mining industry, foundries, flour and powder mills. Pop. 14,000.

Tamar, a river which for 45 miles is the boundary between Devon and Cornwall; its estuary in Plymouth Sound is called the Hamoaze.

Tamarack. See LARCH.

Tamarind, a beautiful tree of the family Leguminosæ, sub-family Casalpinioideæ, a native of the East Indies, but now very generally cultivated in warm climates. Only one species is known (*Tamarindus indica*), a spreading tree 30 or 40 feet high, with alternate pinnate leaves, which have from twelve to fifteen pair of small leaflets, and fragrant flowers, with three petals, the pods brown and many-seeded, as thick as a man's finger, and about 6 inches long. There are two varieties, the East Indian and the West Indian, the former having long pods containing from six to twelve seeds, the latter short pods with from one to four seeds. The pods are filled with a pleasant, acidulous, sweet, reddish-black pulp, in which the seeds are imbedded. West Indian tamarinds are usually imported preserved in syrup, the outer shell having been removed. The wood of the tamarind-tree, and especially of its roots, is a cabinet wood of much beauty, but of extreme

Tamarind (*Tamarindus indica*),
branch in flower:
a, seed-pod section.

hardness, so that it is wrought with difficulty. The pods of some other trees of genera allied to *Tamarindus* are filled with a similar pulp, which is used in the same way, as the Tamarind Plum of India (*Dialium indicum*), and the Brown and Velvet Tamarinds of Sierra Leone.

Tamarind pulp contains citric, tartaric, and malic acids, potash, sugar, vegetable jelly, &c. It is refrigerant and gently laxative, and, in combination with more active remedies, is often employed in the diseases of children. A kind of sherbet is also formed from it; and it is an excellent addition to curries. Cold tamarind tea, made by infusing tamarinds in boiling water, forms an agreeable and cooling drink.

Tamarisk (*Tamarix*), a genus of Tamaricaceæ.

The plants of this family inhabit the warmer parts of Europe and Asia, and of Africa, generally growing in arid situations. Some of them are herbaceous, others are shrubs or small trees, with rod-like branches, scale-like leaves, and small flowers in close spikes or racemes. The Common Tamarisk (*T. gallica*) grows in sandy places in the countries near the Mediterranean, and has been naturalised in some places on the southern coasts of England. It sometimes attains a height of 30 feet. The ashes of this and some other species of the genus contain much sulphate of soda. The Oriental Tamarisk (*T. articulata*) is one of the few trees to be seen in the Arabian and African deserts, where its leafless appearance accords with the surrounding desolation. Galls are found on some species in India, and are valued both for medicinal use and for dyeing. *T. nucumifera* yields a kind of Manna (q.v.). The German Tamarisk (*Myricaria germanica*), belonging to another genus of this family, is a smaller shrub than the common tamarisk, and abounds in many parts of Europe and Asia.

Tamatave, a fortified port and important trading town of Madagascar, on the east coast, on a bay surrounded with reefs, with a good anchorage. Pop. 13,000.

Tamanlipas, the northernmost of the Gulf states of Mexico (q.v.), with part of its low coast bordered by the southern Laguna del Madre. Pop. 288,000. Capital, Victoria (pop. 18,000).

Tamayo y Baus, MANUEL (1829-98), Spanish dramatist, born at Madrid, produced *Genoveva de Brabante*, an adaptation from the French, in his twelfth year. His best plays are *Virginia* (1853), *Lances de Honor* (1863), and *Un Drama nuevo* (1867), his numerous adaptations of French plays being of uneven quality. He became a member of the Spanish Academy in 1858, and director of the National Library in 1884.

Common Tamarisk (*Tamarix gallica*):
a, a flower.

Tambour (Fr. *tambour*, 'drum'), a frame upon which muslin or other material is stretched for embroidering. Tambour-work was extensively employed for the decoration of large surfaces of muslin, &c., for curtains and similar purposes; but pattern-weaving has been brought to resemble it so closely that it has been largely superseded. See EMBROIDERY.

Tambourine, a very ancient instrument of the drum species, much used by the Biscayan and South Italian peasants at their festivities, and sometimes introduced into orchestral music where the subject of the piece is connected with a people who use it. It is composed of a piece of parchment stretched on the top of a hoop furnished with little bells, and is sounded by the hand, fingers, or elbow. When sharply struck by the hand the tambourine has not much effect, unless used in numbers. When sounded by gliding the fingers along the parchment a roll results, in which the bells are chiefly heard; and by rubbing the parchment without quitting it with the whole weight of the thumb the instrument gives out a wild, grotesque sound which is sometimes of service in masquerade scenes. The tambourine is nowadays much used by negro minstrels and Salvationists, and as a surface for young ladies' paintings.

Tambov, a Russian town, 300 miles SE. of Moscow by rail. A university was established in 1919. Pop. 70,000.

Tamerlane, whose proper name was TIMUR or TIMUR-LENK (i.e. Lame Timur), one of the great conquerors who came forth from the heart of Asia during the middle ages, was born at Kesh (or Sebz), some 50 miles S. of Samarkand, in 1336, his father being the chief of a Mongol clan. Tamerlane's youth and early manhood had been full of adventure, when in 1369, having overcome all his rivals and enemies, he seated himself on the throne of Samarkand. The rest of his life, after he had organised the internal affairs of his kingdom, was spent in military campaigns inspired by his lust of conquest. He subdued nearly all Persia, Georgia, and the other Caucasian states, and the empire of the Eastern Kipchaks or the Tatars (in 1390). But the military genius of Toktamish, chief of the Eastern Kipchaks and also of the Western Kipchaks or the Golden Horde, imposed upon Tamerlane a second long and determined campaign; however, in the end (1395) he effectually humbled his former protégé and broke up his empire (see UZBEKS). India was the next object of his ambition. He conquered (1398) all the states between the Indus and the lower Ganges, and returned to Samarkand with a fabulous wealth of booty. He next set out to measure himself against the Turks in Asia Minor; but first turned aside to win Damascus and other strong places in Syria from the Mameluke sovereigns of Egypt. At length on the plains of Angora the Mongol and Turkish hosts came together; and, as the result of a gigantic battle, Sultan Bajazet was taken prisoner and his troops utterly routed. The victorious Tamerlane, after resting awhile at Samarkand, turned his eyes towards China. During the reign of the first Ming dynasty emperor, presents and friendly letters were exchanged; but when that emperor's fourth son in 1402 usurped the throne, 'son-in-law Timur' was reported by the returning Chinese envoy to have been marching against China by way of Bishbalik (Urumtsi), when he died at Otrar on 17th February 1405, his grandson Ha-li (Khalil Shah) succeeding. Otrar (Wo-to-ho-th), on the eastern side of the Syr-Daria, was the first place captured by Genghis in 1219-20. Tamerlane seems to have been in many respects a typical oriental ruler of the abler class: in times

of peace he mingled clemency with justice, and fostered learning and the arts, but in war he was cruel, implacable, and reckless of human life. He is the hero of Marlowe's *Tamburlaine*.

The recognised Life is Petis de la Croix's translation (1722) of one by the Persian writer Sherif ed-Din. See also Sir Henry Howorth, *History of the Mongols* (1876-88), and Sir J. Malcolm, *History of Persia* (1828).

Tamili. See INDIA, Vol. VI. p. 102; also CEYLON.

Tammany Society, a Democratic political organisation of New York City, derives its name from an Indian chief who is said to have signed the treaty with Penn. and round whom many fanciful legends afterwards gathered. Washington's Pennsylvania troops chose him as their patron saint in place of St George; and on his 'day,' 12th May 1789, the society--although at first as the Columbian Order, to rival the Cincinnati (q.v.)--was founded under a grand sachem and twelve subordinate chiefs of tribes. The organisation soon became a party 'machine,' and by its aid Aaron Burr was raised to the vice-presidency. In 1805 the Tammany Society was formally chartered, its professed objects charity and the extension of the franchise. Its first hall was built in 1811, and a second, one in 1867-68; indeed as early as 1822 the society had grown too large, and the management and practically all the power were transferred to a general committee of three delegates from each ward. The political society known as Tammany Hall is nominally distinct from the Tammany Society, but they are virtually identical. Tammany took a leading part in city politics from the first, and flourished steadily. The number of the general committee rose to over 1400, delegates ultimately being sent from each district and precinct; and finally a central 'committee on organisation' was chosen from this unwieldy body, whose chairman was 'boss' of the hall. The most notorious of these 'bosses' was William M. Tweed, whose gigantic frauds, and those of the 'ring' of which he was the chief, were finally exposed in 1871; Tweed was convicted, and died in goal while suits were pending against him for the recovery by the city of \$6,000,000. This catastrophe crippled the power of Tammany, but its influence was by no means killed, though it was unquestionably used entirely for the pecuniary benefit of its leaders. Investigations in 1895 and 1899 showed extraordinary corruption in the police and municipal government, due to Tammany. Yet, in spite of periodical reverses, Tammany retains a firm hold on New York politics, as is seen in its overwhelming victory in 1918. Its power is partly to be ascribed to the efficiency of its machinery, partly to its consistent bid, often through very tangible means, for the sympathies of the lower classes.

Tammerfors, or TAMPERE, an important manufacturing city of Finland, 50 miles NW. of Tavastehus by rail. It is situated on a rapid which connects two lakes, and affords motive-power to cotton, linen, paper, and woollen mills. The first textile factory was established in 1820 by James Finlayson (1771-1852), a Glasgow engineer. Shoes are also made. Pop. (1922) 49,398.

Tammuz. See ASTARTE.

Tampa, Florida, at the head of Tampa Bay (40 miles long), 240 miles SSW. of Jacksonville, ships phosphates, fruits, timber, and cattle, imports tobacco from Cuba, and manufactures vast quantities of 'Havana' cigars. Tampa, a favourite health resort, is connected by a concrete bridge two miles in length with St Petersburg, on the other side of the bay. Pop. 94,700. Larger ships enter at Port Tampa, 9 miles SW., a great starting-point of

steamers for the West Indies and Central America. Government works in 1905-12 greatly improved the channel.

Tampere, Finnish name of Tammerfors (q.v.).

Tampico, a seaport of Mexico in the state of Tamaulipas, on the Panuco, 9 miles from its mouth in the Gulf of Mexico, and 200 miles NNE. of Mexico. Harbour-works (1890-1900), with the help of two jetties thrown out some 5000 feet, over the bar at the river-mouth, permit ships drawing 24 feet to enter. Tampico, which is situated on a small hill and is much healthier than Vera Cruz, has extensive dock and quay accommodation, and shares with Vera Cruz the greater portion of the foreign trade of Mexico. Pop. 20,000.

Tamsui, or HOBEI, a port on the NW. coast of Formosa (q.v.); the harbour is impeded by a bar at its entrance. Pop. 21,000. See FORMOSA.

Tamus. See BRYONY.

Tamworth, a town on the border of Stafford and Warwick shires, at the confluence of the Tame and Anker, 110 miles by rail NW. of London, 17½ NNE. of Birmingham, and 7 SE. of Lichfield. It is near the Roman Watling Street, and was the residence of the kings of Mercia. Burned by the Danes in 874, it was rebuilt by Ethelfleda, Alfred's daughter, who founded a castle, which was afterwards held by the Marnion, Ferrers, Townshend, and other families, and now belongs to the corporation. The castle stands on an artificial mound 130 feet high. The church of St. Editha was founded in the 8th century; the present edifice, which was built in 1345, has some interesting monuments and a curious double tower-staircase. There are also a bronze statue of Peel (q.v.), the municipal buildings and assembly rooms, a town-hall erected (1701) by Thomas Guy (q.v.), a grammar-school (1588; rebuilt 1868), almshouses founded by Guy, a cottage hospital, recreation grounds, &c. The manufactures include elastic, tape, clothing, smallwares, paper, &c.; and in the vicinity are market-gardens and coal and clay pits. A municipal borough, chartered by Elizabeth, Tamworth returned two members until 1885, when it was merged in the county. The county border ran through the middle of the town till 1889; the borough was transferred to Staffordshire for civil purposes in 1889, and for parliamentary purposes in 1918. Pop. (1851) 4039; (1921) 8032.

Tan, FLOWERS OF. See MYXOMYCETES.

Tana, TZANA, or DEMBEA, a great fresh-water lake on the high plateau of Abyssinia, south of Gondar, situated some 6000 feet above sea-level. The greatest length is 60 miles; the breadth varies from 30 to 40; the area is 1181 sq. miles. It is fed by numerous streams and is the main reservoir of the Blue Nile (q.v.), which flows into and out of it under the name of Abai. The lake was probably formed by the damming up this river by a lava stream. The water is clear and full of fish, with hippopotami; there are many small basaltic islands, some of them inhabited. For the regulation of the Nile, it has been proposed to supplement the great reservoir at Assuan (q.v.) by a dam here.

Tanacetum. See TANSY.

Tanagers (*Tanagridæ*), a family of the Passeriformes, or perching birds, containing nearly 400 species; the bill is usually conical (sometimes depressed or attenuated), more or less triangular at the base, with the cutting edges not much inflected, and frequently notched near the tip of the upper mandible. This last character will generally serve to distinguish the tanagers from the finches, to which they are very closely allied; while on the other hand they have strong affinities

to the American Warblers (Mniotiltidæ). They are mostly birds of small size, the largest barely exceeding a song-thrush, and the smallest, some of the genus *Euphonia*, being hardly 4 inches in length. This genus, with its ally *Chlorophonia*, is remarkable in having no gizzard: the birds belonging thereto feed chiefly on ripe fruits, which, with insects, form the principal food of the typical tanagers; some, however, feed on seeds and grain, like the finches. With the exception of a few species which visit North America in summer, the tanagers are confined to Central and South America and the West Indies. Some genera of tanagers are remarkable for their beauty of plumage, which is sometimes confined to the male sex, and sometimes possessed by the female also. Many are also pleasant songsters, such as the Organist Tanager (*Euphonia musica*) of San Domingo; the male of this species has the upper parts purplish-black, the cap blue, and the forehead, rump, and under parts yellow; the female being olive-green, with a blue cap, and lighter and yellowish below. The Scarlet Tanager (*Tyranga rubra*), visiting the eastern parts of North America in summer, and ranging south in winter to Ecuador, Peru, and Bolivia, is also a songster; it is larger than the preceding species, and the male is scarlet, with black wings and tail, while the female is olive, with the wings and tail brown. Tanagers do well in captivity, and several species may usually be seen in the Zoological Gardens.

Tanagra, an ancient city in the extreme east of Bactria, on the Asopus, which suffered constantly in the wars between Athens and Thebes. Great finds of terra-cotta statues and statuettes were made in its necropolis towards the end of the 19th century. See POTTERY.

Tanais. See DON.

Tanarive. See ANTANANARIVO.

Tancred (b. 1078), one of the chiefs of the first crusade, was the grandson of Robert Guiscard, and son of a certain Marchisus, who was perhaps a Lombard prince. Joining his uncle, Bohemund of Tarentum, Guiscard's son, in the first crusade, Tancred specially distinguished himself in the sieges of Nicara, Antioch, and Jerusalem. His reward was the principality of Tiberias. For some time he ruled his uncle's state of Antioch, and shortly before his death, on 21st April 1112, he was invested with the principality of Edessa. Tancred figures in the contemporary chroniclers as the model of crusading chivalry: before Tarsus he quarrelled with Baldwin, brother of Godfrey of Bouillon, but generously made up the quarrel when they came to the Holy City; after the storm of Jerusalem he endeavoured to save some hundreds of the captives from massacre; these and many other noble traits are recorded of him. He is the hero of Tasso's great epic.

Tandy, JAMES NAPPER, Irish patriot, was born in Dublin in 1740, and became a prosperous and popular merchant there. One of the chief Protestant leaders of the popular interest, he took an active part in corporation politics, the free-trade agitation, and especially in volunteering affairs, and became the first secretary to the United Irishmen of Dublin. Early in 1792 he challenged the solicitor-general, Toler, for his abusive language, and was ordered to prison till the close of the session by the House of Commons for breach of privilege. As the viceroy had proclaimed him, with a reward for his apprehension, he had the temerity to raise a formal action for illegality against him and his privy-councillors, which was dismissed at the final hearing on November 26. For distributing in County Louth a 'seditious' pamphlet against the corruption of the powerful Beresford family he

was about to be tried at the Dundalk assizes in the spring of 1793, when the government discovered the graver matter that he had met the Defenders at Castle Bellingham in County Louth, and taken their oath, with the view of effecting a coalition between them and the United Irishmen. Tandy fled to America, lived awhile at Wilmington in Delaware, and crossed to France in the spring of 1798, where Madden assures us he was raised to the rank of a general of division in the French army. He followed the ill-fated invasion of Ireland, and made a futile landing at Rutland Island, 16th September 1798, but returned on board that same night. He made his way to Norway, thence to Hamburg, the senate of which handed him over to the English government. On 12th February 1800 he was put on his trial at Dublin, but acquitted. But he was detained in custody, and again put on trial (7th April 1801) at Lifford, in County Donegal, for the treasonable landing on Rutland Island. This time he was convicted and sentenced to death, but, from the same motives of policy that engendered the peace of Amiens (27th March 1801), was permitted to make his way to France. He spent the rest of his days at Bordeaux, dying there in 1803. See Dr R. R. Madden's *United Irishmen* (3d series, vol. i. 1846).

Taney, ROGER BROOKE, American jurist, was born the son of a Maryland planter in 1777, admitted to the bar in 1799, and elected to the state senate in 1816. He was a courageous opponent of slavery as early as 1819. In 1824 he passed from the Federal into the Democratic party, and supported Andrew Jackson, who in 1831 appointed him attorney-general of the United States, and in 1833 secretary of the treasury. He encouraged and carried out the removal of the government deposits from the United States Bank (see JACKSON), and in June 1834 the senate for the first time refused to confirm a president's nomination of one of his cabinet officers. But the balance of parties changed, and in 1836 the senate confirmed his appointment as chief-justice of the United States. His early decisions were strongly in favour of the doctrine of state sovereignty (see STATES' RIGHTS), but his most famous decision was that in the Dred Scott Case (q.v.). He died 12th October 1864. There is a Memoir (autobiographical to 1801) by S. Tyler (1872).

Tanganyika, a lake of Eastern Central Africa, lying between 3° and 9° S. lat., long. of centre being 30° E.; length, 420 miles (nearly a fifth longer than Lake Michigan); breadth, from 15 to 56 miles; maximum depth, 4758 feet. It was discovered by Speke and Burton in 1858. Livingstone and Stanley disproved in 1871 the theory till then accepted that the lake belonged to the Nile basin. Cameron surveyed the south and west coasts in 1874, and discovered an outlet, the Lukuga, on the west side. In 1876 Stanley satisfied himself that this channel, which he proved to communicate with the Lualaba or Upper Congo, is generally dried up in certain parts of its course, and only carries the overflow of Tanganyika westward at intervals of years. Thomson reaffirmed the connection between Tanganyika and the Congo by the Lukuga. Hore found the height of the surface in March 1879 to be 2700 feet above sea-level; in August 1880 the water had fallen 10 feet 4 inches. He believed that the lake had gradually for several years been rising to the former, apparently its highest level, that the obstructions in the Lukuga had then been carried away. The Lukuga has since been alternately blocked and open. Except when several rainy seasons follow one another, the evaporation keeps the water about the same level; the evaporation is so great that the opposite shores, even if only 15

miles distant, are visible only in the rainy season. The water is slightly brackish, the climate not unhealthy. The lake is surrounded by high mountains, some of them attaining a height of 10,000 feet. The scenery is beautiful, and the shores abound in animals of all kinds. It is 600 miles from the coast; separates Belgian Congo from Tanganyika Territory; has its south end in Northern Rhodesia; and as a link of connection between the Zambezi basin and the Nile is in a very true sense the heart of Africa. There are a number of good harbours and anchorages on the shores of the lake, and a considerable trade is carried on. See Moore's *Tanganyika Problem* (1902).

Tanganyika Territory consists mostly of the region on the east coast of Africa formerly known as German East Africa. It is bounded by Kenya, Uganda, Belgian Congo, Northern Rhodesia, Nyasaland, and Portuguese East Africa, and has a coast-line of rather less than 500 miles on the Indian Ocean. Area, 370,000 sq. m., with a population of 4,107,000, excluding the Rionda and Urundi districts (under Belgian administration), with an area of 20,000 sq. m. and a population of 3,500,000. The people are largely of Bantu race, much subjected to external influences, Hamitic (Wahimas, Masais) in the NW. and N., Wangoni in the S., and Arab-Swahili on the coast. Traces are still found of the aboriginal Bushman race in the western interior. Bantu dialects make up the speech of most of the inhabitants, though Kiswahili (a mixture of Arab and Bantu) is the *lingua franca* throughout. Mohammedanism is the chief religion on the coast; paganism prevails inland, though missionary enterprise is enthusiastically prosecuted by numerous sects.

Except for the coastal plain, from 10 to 40 miles in width, most of the country forms an elevated plateau, rising to higher ground in the west, north (Mount Kilimanjaro, 19,680 feet, and Mount Mern, 14,960 feet), and south (Livingstone Mountains, over 9000 feet). The Rufiji and Pangani rivers are navigable to some extent, but the Rovuma, on the southern border, is difficult. The boundary takes in Lakes Victoria, Kivu, Tanganyika, and Nyasa; others of note are Lake Rukwa in the south-west, and the three salt lakes, Natron, Eyasi, and Manyara in the north. Most of the country is in the path of the south-east trade-winds, and has a dry season from June to August and heavy rains from December to February. On the coast the climate is damp though equable, but in the interior there are great extremes, and in some districts scanty rainfall. The high ground is generally healthy for Europeans, though malaria is everywhere prevalent. Blackwater fever, dysentery, tick-fever, and typhoid are other maladies which science is attempting to subdue.

Agriculture is by far the most important occupation. The regions of greatest fertility are the Usambara district in the NE., the Ruandi, Urundi, and Bukoba districts in the NW., and the Mahenge area in the south. The principal exports are sisal, cotton, coffee, ground-nuts, grains (sorghum, maize, millet), copra, hides and skins, sim-sim, wax, gili, rubber, sugar, some spices, copal. Stock-raising is important, especially in the NW., where the ravages of rinderpest and of the tsetse-fly are less marked. Horses are little used. Extensive forests in the north and south, nearly all in government reserves, produce cedar, yellow-wood (East African pine), and ebony; there are also teak, mahogany, bamboo, and baobab. The ancient system of land-tenure on a tribal and communal basis, still largely obtains; native rights, however, have been frequently violated by foreigners, and much discontent has sometimes arisen. There is little industry beyond basket and mat weaving, metal-

working, and pottery. The chief minerals are coal, iron, gold, lead, copper, mica, salt, and some pitchblende. Garnets, agates, tourmaline, topaz, moonstones, and some diamonds are found. Trade, carried on largely by Arabs and Indians, flourishes mostly in the coast towns, though regular markets are held in most districts of the interior. Communications were considerably developed by the Germans, who built the Usambara railway (219 miles) and Central line (from Dar-es-Salaam to Kigoma on Lake Tanganyika, 772 miles). Caravans and pack-animals are giving way to motor traffic. There are many good natural harbours along the coast in spite of coral reefs and bars; the largest are Dar-es-Salaam, Tanga, Bagamoyo, Lindi, and Kilwa-Kisiwani. Mwanza on Lake Victoria is the most considerable of the numerous lake-ports, but is very unhealthy. Tanganyika has a uniform customs tariff with Kenya and Uganda.

History.—The Portuguese first set foot on the East African coast in 1505. At the end of the 17th century power passed to the Imams of Muscat, and in the 19th century the Sultan Seyyid Said, who made Zanzibar his headquarters in 1832, came to rule over the littoral of what is now Kenya and Tanganyika. In the eighties of last century the Germans, pursuing ideas of colonial expansion, began to annex large tracts of territory in East Africa, and finished by proclaiming an Imperial German Protectorate, arranging the boundaries by a treaty with Great Britain in 1890. The Germans did much for the economic and intellectual betterment of the country, but were much afflicted with native insurrections, especially in 1905. After a lengthy campaign during the Great War, Germany lost the colony, and the Treaty of Peace (1919) gave Great Britain a mandatory power over most of it, the districts of Ruanda and Urundi being assigned to Belgian administration. The mandate, approved by the League of Nations, lays down conditions as to slavery, forced labour, usury, traffic in arms and spirits, and security of land-tenure. The policy of the government is educational, and aims at establishing native administration. The governor has his seat at Dar-es-Salaam, and is aided by an executive council and the district commissioners of the twenty-two administrative areas into which the country is divided. See F. S. Joelson, *The Tanganyika Territory* (1920).

Tangent. See TRIGONOMETRY; and for Tangent sailing, see GREAT CIRCLE SAILING.

Tanghinin is a crystalline body extracted from the kernel of *Cerbera tanghin* (family Apocynaceae), which grows in Madagascar. It is a deadly poison, acting upon the heart like digitalis, strophanthus, and their allies, but possessing a convulsant action which these lack. Like digitalis it excites vomiting. Tanghin, an extract made by the Malaysians from the kernel, was used by them for the judicial Ordeal (q.v.).

Tangier, or TANGIERS (Arab. *Tanja*), a seaport of Morocco, on a small bay or inlet of the Straits of Gibraltar, 38 miles SW. of the town of that name. The town is surrounded by old walls, and is situated on two hills, the houses being, as a rule, miserable edifices, and the streets narrow and dirty. It has an extensive shipping trade, and is patronised as a holiday-resort by Europeans. Tangier was taken by the Portuguese in 1471, and given to Charles II. of England as dowry with Catharine of Braganza. It was held by England till 1683, when, on account of the expense and the badness of the climate, it was evacuated and the fortifications dismantled. The notorious Colonel Kirke (q.v.) commanded the garrison, and Bishop Ken was for a short time chaplain. It was subsequently long a nest of pirates. Its harbour was for long a mere roadstead.

An international company was formed in 1910 to undertake the construction of a harbour, but no progress was made for fourteen years. The scheme was revived in 1924. The town has been the subject of much political controversy in recent years. The Franco-Spanish treaty of Madrid (1912) constituted Tangier and the adjoining region an international zone. This agreement was strengthened by a convention between Britain, France, and Spain in 1923, which came into force in 1925. It declares Tangier a neutral and unfortified zone, and provides for general administration by a chief administrator and assistants, for native administration by a *meudub* (the representative of the Sultan of Morocco), for a Committee of Control (composed of the consuls of various powers), and an International Legislative Assembly (26 members). The administration of justice is also on an international basis. The convention, however, has not been accepted by all the powers, and Tangier remains in a position of uncertainty which is preventing its economic development. Pop. 50,000 (26,000 Moors, 12,000 Jews, and 12,000 Europeans).

Tangle, a name given to various kinds of Sea-weeds (q.v.), especially to Laminaria.

Tango, a dance associated with Mexico and with the Argentine but probably of African origin, is rather faster than the Habanera, but is of the same nature—languorous and graceful. It has been considerably modified in Paris. The rhythm is duple (in *Andante* time), one of the beats often consisting in a triplet. Millaud and other French composers have written tangos for concert performance.

Tanis (Greek form of Egyptian *T'an*; Heb. *Zaan*), an ancient Egyptian city in the north-east of the Delta, once the chief commercial city of Egypt, capital of the Hyksos kings about 2100 B.C., and of Rameses II. and other great monarchs of the 19th dynasty. Its prosperity was destroyed by the silting up of the Tanitic mouth of the Nile, which was named from it, and it was destroyed by rebellion in 174 A.D. The ruins near the fishing-village of Sān el Hager near the south shore of Lake Menzaleh were examined first by Mariette, and in 1883-84 explored by Flinders Petrie. See the explorer's monograph (1885).

Tanistry, an ancient Celtic mode of tenure, according to which the right of succession lay not with the individual, but with the family, in which it was hereditary; and by the family the holder of office or lands was elected, the design doubtless being that power should in this way be reserved for the strongest or worthiest of the stock—other things being equal, the nearest male relative of the actual tanist in possession. In the case of a monarchy it was the custom to appoint the heir-apparent during the lifetime of the sovereign; and there is no doubt that the nearest to the original stock was held to have a preferable claim, as contended by Bruce in his claim to the Scottish throne.

Tanjore (*Tanjūr* or *Tanjāvár*), a town of India, capital of a district in the Madras province, 218 miles SSW. of Madras city, in the midst of an extensive plain, on one of the branches of the lower Kaveri. The principal edifices of Tanjore are the great temple, described with an illustration at PAGODA, the palace of the old rajahs, and a dismantled fort. Once a famous Hindu capital, it was a great centre of learning and religion. Silks, jewellery, carpets, copper vessels, and artistic models in clay, &c., are manufactured. Pop. (1921) 59,913.

Tanks, the name applied by the British army to the armed and armoured automobiles used by it

on the battlefields of northern France during the Great War. Their construction was suggested in 1914 and experiments were conducted—at first largely on naval initiative—but tanks did not appear in action till 1916, and were not definitely successful till 1917. They were also used by the French, and, to some extent, by the Americans and Germans. Numerous modifications in design were effected in later models, but in the main the first British tank, the *Mark I.*, supplied the essential features. Gaunt and grim in appearance and rhomboidal in shape, it moved on the Caterpillar Tractor (q.v.) system, propelled by a high-powered petrol motor. Although tanks had been experimented with in order to provide a means of transport for infantry over bullet-swept ground, it was recognised that their chief utility lay in their ability to crush barbed-wire entanglements and attack machine-gun lairs with impunity. They were impeded, however, by their slowness of speed, by their cumbersome, and by their inability to operate in mud. These difficulties were partly met by the construction of smaller and speedier tanks (*Whippets*), about half the weight of the full-sized type. The normal armament consists of some half-dozen machine-guns, though frequently two six-pounder guns are carried. The crew usually numbers eight, but the smaller tanks carry only three or four, while experiments have been conducted with a 'one-man tank.'

See A. G. Stern, *Tanks, 1914-18*; D. G. Browne, *The Tank in Action* (1920); J. F. C. Fuller, *Tanks in the Great War* (1920).

Tannahill. ROBERT, poet, was born at Paisley, the son of a hand-loom weaver, on 31 June 1774. He eagerly read Burns, Feigussan, and Ramsay; and having been put to the loom after leaving school, he composed many of his best songs to the music of the shuttle. In 1800 he went with a brother to Lancashire, and remained there till 1802, when he returned to Paisley on hearing of his father's failing health. By the year 1805 his poems had become well known in the town, and a number of friends advised him to have them published. In 1807 he issued a volume of 175 pages entitled *Poems and Songs*, of which an edition of 900 copies was sold in a few weeks, to the profit of the author, who was able to deposit twenty pounds in the Union Bank. The poet was now famous, and heard his songs sung everywhere, special favourites being *Gloomy Winter's noo awa*, *Jessie the Flower o' Dunblane*, *The Braes o' Gleniffer*, *Louison's Bonnie Woods and Braes*, and *The Wood o' Craighuelen*. In 1810 the Ettrick Shepherd came to Paisley, and spent a night with Tannahill, who the following day conveyed Hogg half-way to Glasgow. It was a melancholy adieu Tannahill gave him. He grasped his hand, tears gathering in his eyes the while, and said: 'Farewell, we shall never meet again; farewell, I shall never see von more'—prophetic words soon to be verified. He had arranged a corrected edition of his works for the press, and offered them to Mr Constable, who returned the manuscript, as he had more new works on hand than he could undertake. This rebuff the poet was unable to bear, and he sank into despondency; two days before his death he threw into the fire all his new songs, nearly a hundred in number. On 17th May 1810 his body was found in a canal near Paisley; and there seems no reason to doubt that his death was that of the suicide. A granite obelisk marks his grave in the burying-ground of the West Relief (Canal Street) Church; and in 1883 a statue was erected in Paisley as a memorial of the poet. As a songwriter Tannahill continues to be remembered; and several of his pieces have established themselves as part of the musical repertory of the

Scottish people. He has a genuine lyrical gift, much tenderness of sentiment, and a true eye and feeling for the simple effects of nature with which he was familiar. Of Burns's force and passion he has little; but in grace and sweetness Burns himself has scarcely surpassed his happier passages. See *Life in Sample's* edition of his poems (1876), and Brown's *Paisley Poets* (vol. i. 1889).

Tannenberg, a village of Masuria in East Prussia, 10 miles SW. of Hohenstein. It has been the scene of two historic battles. Here on July 15, 1410, the Poles and Lithuanians defeated the Teutonic knights (the battle is sometimes given the name of Grünwald; see POLAND, TEUTONIC KNIGHTS). Here also on August 26-31, 1914, a German army under Von Hindenburg (q.v.) shattered an invading Russian army under General Samsonov, who shot himself after the battle.

Tanner. THOMAS, was born at the vicarage of Market Lavington, Wiltshire, January 25, 1674, and after graduating from Queen's College, Oxford, was in 1696 elected a Fellow of All Souls. He had already a high reputation as an antiquary, and Wood at his death in 1695 left him the care of his papers. He took orders, and became in succession chaplain to his father-in-law, Bishop Moore of Norwich, chancellor of Norwich, prebendary of Ely, rector of Thorpe near Norwich, archdeacon of Norwich (1710), canon of Christ Church, Oxford (1723), and Bishop of St Asaph (1732). He was thrice married, and died at Oxford, 14th December 1735. An improved and enlarged edition of his *Notitia Monastica* (1695) appeared in folio under the cue of his brother in 1744. But Bishop Tanner's fame rests hardly less securely on his great posthumous biographical and bibliographical work—the labour of forty years, the *Bibliotheca Britannico-Hibernica* (ed. by Dr D. Wilkins, 1748). His edition of Wood's *Athene Oxonienses* he had published in 2 vols. folio in 1721.

Tannhäuser, the hero of one of the most beautiful of mediæval German legends, is a knight who, in the course of his travels, comes to the Venusberg, and enters the cave-palace to behold the wonders of the Lady Venus and her court. After having lived there some time in every kind of sensual delight, his conscience smites him, he invokes the Virgin Mary, and makes a pilgrimage to Rome, to Pope Urban, to seek, through confession and penance, remission of his sins, and escape from damnation. But the pope, when he hears his story, tells him that he can as little obtain God's mercy as the rod in his hand can become green again. Thereupon Tannhäuser departs in despair, and returns to the Lady Venus in the mountain. Three days after he had gone the dry rod begins to sprout and bear green leaves; and the pope immediately sends out messengers to every country, but in vain, for the knight can nowhere be found. Such is the story as told in the popular ballad once common all over Germany, and even beyond it. Elsewhere it is added that 'the faithful Eckhart,' of many German heroic legends, sits before the mountain, and warns the people of its dangers. In this shape the story may be traced as far back as the 14th century, but the substance of the legend is much older, and goes back to the days of German paganism. Some traditions connect it with the Hoeselberg or Hørselberg, near Eisenach, in which the Lady Hulda (see BERCHTA) held her court, who again suggests Freyja the Scandinavian Venus. Grimm sees in the legend a touching portrayal of the regret that lingered in the popular heart for the dying paganism, and of the sternness of the Christian priesthood in regard to it. This idea of subterranean palaces in which the kings or queens of

dwarfs, pygmies, and fairies held their courts seem to be universal. Everywhere stories are told of men, like Thomas of Erildoune, being enticed to enter, and finding it difficult or altogether impossible ever again to obtain their liberty. The visits of Ulysses to the isle of Calypso and to that of Circe are amplifications of the same idea. In later times the story has been treated by Tieck, and gave the subject for an opera to Wagner.

About the middle of the 13th century, and contemporary with Pope Urban IV. (1261-65), there lived in reality in Germany a Bavarian knight named Tannhäuser, who, as Neidhart relates, after returning from the wars, lived as a minnesinger at the court of the Austrian Duke Frederick II. the Quarrelsome, and after his death either with Duke Otto II. of Bavaria, or wandering from place to place. Tannhäuser composed fine spirited ballads.

For the legend, see Zander, *Die Tannhäuser-sage und der Minnesänger Tannhäuser* (1858); Grässe, *Der Tannhäuser und ewige Jude* (2d ed. 1861); P. S. Barto, *Tannhäuser and the Mountain of Venus* (1917).

Tannin, Tannic Acid, or DIGALLIC ACID, is an astringent substance found in gall-nuts, and hence called gallotannic acid. The name tannin has, however, been applied to a number of different astringent compounds existing in the bark or leaves of most trees. These compounds, though not intimately related to each other, yet agree in giving blue or green-black compounds with salts of iron, and in producing leather by their action on animal skins. The true tannic acid is a colourless amorphous body, obtainable in fine scales or vitreous masses by the evaporation of its solution. A yellowish colour soon develops in the acid even when excluded from light. It is readily soluble in water and alcohol, but insoluble in chloroform. It reddens litmus, and has a powerful astringent taste and local action. On this account it is employed for relaxed throats as a gargle, or in the form of lozenge. As a styptic it is of much value. In the arts it is employed in the manufacture of ink, although most makers employ the crude gall-nuts in preference to the purified acid. The various tanning substances containing the other varieties of tannin are more employed in leather-making and dyeing (q.v.).

Tanning. See LEATHER, BARK.

Tansy (*Tanacetum vulgare*).

Tansa, a small river whose valley has been, at a point 53 miles N. of Bombay, impounded for the water-supply of Bombay. The embankment, rivaling the great Assuan Nile dam in size, is a little short of 2 miles long, 118 feet high, and 100 feet thick at the bottom, and contains over 11,000,000 cubic feet of masonry—all solid stone. The area of the dam is about 8 square miles.

Tansy (*Tanacetum*), a genus of Composite (Tubuliflorae)

allied to *Artemisia* (see WORMWOOD), and having hemispherical heads of flowers, with the florets all tubular, the receptacle naked, the pappus a

slight membranous border. The species are pretty numerous, and are natives of the temperate parts of the Old World. Common Tansy (*T. vulgare*) is a native of Britain and of continental Europe, growing in fields and by roadsides, river-banks, &c. It has long been generally cultivated in gardens. It is now naturalised in many parts of North America. It is a perennial, from 2 to 4 feet high, with great abundance of deep-green, bipinnatifid, inciso-serrate leaves; the flowers in terminal corymbs, yellow, and rather small. The leaves and flowers have a strong aromatic smell and a bitter taste. The young leaves are used for flavouring puddings, cakes, omelets, &c. The plant is also tonic and anthelmintic, and *Tansy tea* is an old popular medicine. Some curious old customs still linger in many parts of England connected with the use of *Tansy cakes* and *Tansy puddings* at Easter, which was originally intended to represent the use of bitter herbs at the Paschal feast.

Tanta, an important town and railway junction of Lower Egypt, between the Rosetta and Damietta branches of the Nile, with a famous mosque, and a great fair; pop. 74,000.

Tantalion Castle. See NORTH BERWICK.

Tantalum (sym. Ta; atom. wt. 181; atom. number 73) is a rare metal, discovered by Hatchett and by Ekeberg in 1801-2, and found associated with columbates in columbite, tantalite, and ytrotantalite. In 1904-5 it was first isolated in purity (Moissan's preparation in 1902 being brittle and impure) by Werner von Bolton, both by an electrical and by a chemical method. It has a high melting-point, 2300° C., and is extremely hard. Tantalum wire is used as the filament in incandescent electric lamps.

Tantalus, said to have been the son of Zeus and father of Niobe, for having divulged the divine counsels was afflicted in the lower world with an insatiable thirst, and had to stand up to the chin in a lake, the waters of which receded whenever he tried to drink of them; and clusters of fruit hung over his head, which eluded his grasp whenever he endeavoured to reach them.

Tantalus, or WOOD-IBIS, a genus of birds of the stork family (Ciconiidae), quite distinct from the true ibises. The American Wood ibis (*T. locustator*) is as large as a stork, but more slender, white, with black quill and tail feathers, the naked skin of the head and neck black. It is especially at home in South America, but also occurs in the southern states in swampy districts, and breeds abundantly in Florida. An allied African form, *Pseudotantalus rhodinopterus*, was for long regarded as the sacred ibis of the Egyptians, but this was a true ibis (*Ibis aethiopica*).

Tantia Topee, the most notable leader under Nana Sahib (q.v.) of the Indian Mutiny, who, in alliance with the Rani of Jhansi, held the field for a time after his chief had fled. He hid in the jungles of Central India till 7th April 1859, when he was captured and executed.

Tantra. See SANSKRIT, Vol. IX. p. 90.

Tantura. See DORA.

Taoism, the religious system founded by Lao-tze (q.v.). See also CHINA; F. H. Balfour, *Taoist Texts* (1884); J. Legge's *Texts of Taoism* (1891); De Rosny, *Le Taoisme* (1892); R. K. Douglas, *Confucianism and Taoism* (1906); E. H. Parker, *Studies in Chinese Religion* (1910); H. A. Giles, *Confucianism and its Rivals* (1914). There are translations of the Tao-Teh King by E. H. Parker and I. Mearns.

Taormina, a town on the east coast of Sicily, on a lofty rock 650 feet above the sea, 30 miles

SW. of Messina by rail. The ancient Tauro-menium was founded in 397 B.C.; it has numerous relics of antiquity of the Roman period, such as some large cisterns, a small theatre (called the Odeon) traces of houses, tombs, &c., and the remains of a Roman theatre, reckoned one of the most splendid ruins in Sicily, and commanding a view of almost unparalleled magnificence over Etna and the Straits of Messina. There are some fine specimens of both Romanesque and Gothic architecture in the modern town; and the place is in great favour as a winter resort. Pop. (1921) 4980.

Tapajos, a navigable river of Brazil, and an affluent of the Amazon, is formed by the confluence of the Arinos and the Juruena, both of which rise in the south of Matto Grosso state. After a northward course of 900 miles, the Tapajos falls into the Amazon, above the town of Santarem. Steamers run 150 miles to the lowest of several waterfalls. A short portage separates the upper waters of the Tapajos from those of the Paraguay.

Tapestry is an ornamental textile used for the covering of walls and furniture, and for curtains and hangings. In its method of manufacture it is intimately related to oriental carpets, which are made in precisely the same way as certain kinds of tapestry, the only distinction being that carpets are meant for floor-coverings alone. Fine storied tapestries are, however, much more elaborate and costly than any carpets, and they have altogether different artistic pretensions. Tapestries are divided into two classes, according as they are made in high-warp (*haute lisse*) or low-warp (*basse lisse*) looms. The former in manufacture have their warp-threads stretched in a vertical manner with a roller at the top around which the warps are wound, and another at the bottom for receiving the finished tapestry. On the low-warp looms the warp is extended horizontally, there being an arrangement in both for shedding or separating the warp into two leaves, front and back, as in ordinary weaving. It is in high-warp looms that the most elaborate storied or pictorial tapestries are made, low-warp looms being more largely devoted to the production of still-life and non-pictorial decorative compositions. Notwithstanding these differences, it is difficult to distinguish between tapestries which have been made on high and low warp looms respectively, although the latter are more rapidly and consequently less expensively woven. In reproducing a design on the high-warp loom the workman has the portion of the cartoon he is copying behind him. He works from the back or wrong side of the tapestry, and to guide him the outline of the subject is slightly indicated on the warp threads. He has an endless number of shades and tones of wool and silk (formerly gold and silver threads were also used) which, with little shuttles, he shoots through the number of warp threads required for each particular shade, and with such wefts he covers and entirely encloses the warp-threads. In the reproduction of a design the utmost skill and experience are essential, not only to outline the figures and composition generally with accuracy, but also for the proper grading and hatching in of tones to secure the rich and mellow harmonies which constitute the principal charms of a picture. In low-warp tapestry-weaving the design to be copied is placed under the warp, and, as the workman here also weaves from the back, the design is reversed in the finished production. Of late years only it has become the habit to trace a reverse drawing on the warp-threads, whereby the tapestry is made to show the design as originally composed. The difficulty of examining low-warp work as it

proceeds prevents the elaborate and delicate work being produced by this method which it is possible to secure on high-warp looms. The best work of Arras, Brussels, and of the Gobelins, for example, is almost entirely high-warp.

The art of tapestry working is of great antiquity. It was practised by the ancient Egyptians and Greeks, and had reached a high degree of importance even by the time of Penelope and her loom. It may be that the curtains of the tabernacle 'of blue and purple and scarlet, with cherubim of cunning work' (Exod. xxvi. 1), were a kind of tapestry, though more probably they were of needle-work. The art was continued by the Romans, and later by the Copts, and during the Dark Ages was kept alive in the monasteries. The fourteenth century marks a turning-point in the history of tapestry—for the Bayeux Tapestry (q.v.) is really just embroidered work. The decay of feudalism transformed the baronial castle into a home of culture, while the Crusades gave to Europe a more comfortable and luxurious standard of living. Indeed, the debt to the East was realised so much that frequently the tapestries were known as *Sarrasinois*. The first important 'period' or 'school' was that of Paris, centering round Nicolas Bataille at the end of the fourteenth century, and terminating with the disturbances of the Hundred Years' War. Paris was succeeded by Arras, which, under the munificent patronage of the Dukes of Burgundy, became supreme in the first half of the fifteenth century to such an extent that the word 'arras' passed into common parlance. Flemish weavers (*tapisiers*) from Tournai, Bruges, &c., were in great demand all over Europe, especially in England and in Italy, but Flanders temporarily declined before the victories of Louis XI. The next century witnessed the triumph of Brussels under the influence of the Italian Renaissance. This collaboration of Italian artists and Flemish craftsmen, which lasted half a century, began with Raphael, who in 1515 sent to Brussels the famous cartoons illustrating the Acts of the Apostles, to be worked into tapestries for the Sistine Chapel. The Renaissance work perhaps lacks some of the naïveté and spontaneity of the earlier Gothic periods, but is more dramatic, relying on broad effects of line and space, and the weaver was, of course, always allowed a considerable amount of discretion in choice of colours. The supply could not meet the demand, and gradually the workmanship became hasty, careless, and slipshod, faults not entirely remedied by the signing of tapestries and introduction of guild restrictions. Oudenarde was the other principal centre of weaving, but the Spanish wars drove many weavers to seek refuge in Italy, where the Barberini, the d'Este, and other noble families set up workshops, and in England, where Henry VIII. had a huge collection of tapestries. It must be remembered that tapestries were extensively used for both inside and outside decorations even as early as Chaucer's day, and consequently formed a common and acceptable gift on occasions of embassies, marriages, and state celebrations generally. The subjects were taken from biblical, mythological, and even sometimes contemporary sources.

There were three outstanding events in the seventeenth century. First, the institution of royal workshops in Paris under two Flemings, Comans, and de la Planche, in the reign of Henry IV., who granted them special privileges and facilities. Second, the supremacy of Mortlake in England, under Sir Francis Crane, who received the patronage of Charles I. (It is worthy of remark that English wool had always formed the staple for the finer qualities of the fabric.) Third, the foundation at Paris in 1664, under Charles

Lebrun, of the famous Gobelins factory, which Louis XIV. intended to be the nucleus of gold and silversmiths' work, and other applied arts. Ambrosson and Beauvais were also centres of industry. The Gobelins were at their most brilliant up to about 1690, when they suffered eclipse owing to the disastrous wars in the Netherlands, but they reappeared next century. The actual dimensions had now become smaller to suit the style of Les Triangons, but contemporary artists, such as Boucher, were again employed to design the cartoons. Of all the modern attempts to continue the art of tapestry-weaving by far the most interesting has been that of William Morris (q.v.) at Merton Abbey in 1881. Many modern artists, in supplying cartoons for copying, do not rely sufficiently on bold, decorative treatment, but make the mistake, if not of rivalling, at least of copying oil-paintings with all their subtle harmonies and minuteness of detail. Fine examples of European tapestries are to be found in various museums, churches, palaces, &c., but the following are especially noted for their collections—South Kensington Museum, Hampton Court, Royal Palace at Madrid, Gobelins factory in Paris, Museum of Bern, the Vatican, and Metropolitan Museum of New York.

See monographs and catalogues of the various collections; the huge *Histoire Générale* (1874-84) of Guiffrey, Pinchart, and Muntz; the standard general histories in French by Muntz (1883, tr. 1885) and Guiffrey (1886), and in English by Thomson (1906); the smaller books by Hunter (1912) and Candee (1913); Migeon, *Les Arts du Tapis* (1909); the work on the technical side of weaving by Christie (new ed. 1920); and the Bibliography of Tapestry by Guiffrey (1904). Most of these books are profusely illustrated.

Fig. 1.—Head of *Taenia solium* (Leuckart).

from one another, are usually longer than broad, are almost always provided with marginal genital

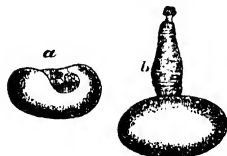

Fig. 2.—Bladder-worm of the Pig (*T. solium*): a, with invaginated head, about natural size; b, with evaginated head, a little bigger than natural size (Leuckart).

The adult sexual *Treniadae* live for the most part in the intestine of mammals, birds, and fishes; the larval Bladder-worms (q.v.) or *Cysticerci* occur in

both vertebrates and invertebrates; and the general rule is that the host of the bladder-worm forms part of the ordinary food of the host of the tapeworm.

In the *Bothriocephalidae* the head is oval and flattened; the two suckers are elongated muscular pits, lying opposite one another longitudinally; the hooks, if present at all (*Trienophorus*), are not borne on a rostellum; the 'joints' are broader than long; there are three genital apertures on the middle of the ventral surface, through one of which (uterine) some of the developing eggs may escape before the joint breaks off; the embryos are ciliated and able to swim about in water; the cysticercoid stage occurs in fishes, and is elongated and solid, not like a bladder. The most important genus is *Bothriocephalus*.

Several tape-worms are in their adult sexual state

parasitic in man: *Taenia solium*, with the bladder-worm stage in the pig; *T. saginata* or *mediocanellata*, with bladder-worm in the ox; and some others, *T. evanescens*, *T. nana*, *T. flavomaculata*, and *T. madagascariensis*, occasionally occur. They infest the small intestine, and there also *Bothriocephalus latus* (larval in pike and burbot) may be found. Moreover *Tenioid* bladder-worms also occur in man, the most important being that of *Taenia echinococcus*, which lives as an adult tapeworm in the dog.

In the majority of cases man becomes infected with tapeworms through eating the raw or imperfectly cooked flesh of the animal—he is ox or pig or fish—which is the host of the immature stage of the parasite. In other cases filthy habits of living and eating render it readily possible for the bladder-worm—or, in the case of *T. echinococcus*, the ova—to get mixed up with the food. The presence of tapeworm in the small intestine need not be dangerous—indeed, the Abyssinians regard freedom from the parasite as a disaster; but it is usually troublesome, giving rise to disturbances of digestion, colic-like pains, diarrhoea, or, on the contrary, constipation, besides less local effects, such as anæmic and neurotic states. No certain diagnosis is possible, 'unless the eggs or proglottides of the *corpus delicti* be observed, and these must always be identified before so radical a cure as treatment with anthelmintics is begun.' Of these anthelmintics—which are intended to expel the parasite from the intestine—there is no lack in the pharmacopœia. Thymol is one of the most effective, but prevention is always better than cure.

See Leuckart, *The Parasites of Man* (trans. by Hoyle 1886); Braun, *The Animal Parasites of Man* (1903); and, for tapeworm in dogs, *WORMS*.

Tapioca, a farinaceous substance obtained from cassava or manioc (when prepared as explained at MANIOC) by drying it whilst moist on hot plates, so that the starch grains swell or burst, and the whole agglomerates in small lumps. The name is sometimes given to a kind of Sago (q.v.) and to a preparation of potato starch.

Tapir (*Tapirus*), a genus of Ungulata, of the section Perissodactyla, having a bulky form, with

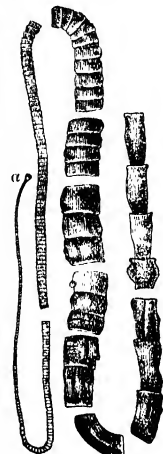

Fig. 3.—Portions of *Taenia mediocanellata*, about half natural size (Leuckart).

moderately long legs; the fore-feet four-toed, the hind-feet three-toed; the skin thick, the hair short; the tail very small; the neck thick; the ears short; the eyes small; the muzzle elongated; the nose prolonged into a short, flexible proboscis, which, however, is not prehensile, like that of the elephant; six incisors, two canine teeth in each jaw, and fourteen molars in the upper and twelve in the lower jaw, the molars separated from the canine by an interval. There are certainly four species, of which three are American and one Oriental. The best known is the American Tapir (*T. terrestris*), which is about the size of a small ass, and is common in almost all parts of South America, its range extending as far south as the Strait of Magellan, although it suddenly ceases to be found at the Isthmus of Panama. Its colour is a uniform deep brown, but the young are—as in many other animals (e.g. the Puma) which when adult are of all one colour—marked with yellowish fawn-coloured stripes and spots. The skin of the neck forms a thick rounded crest on the nape, with a short mane of stiff hair. The tapir inhabits deep recesses of the forest, and delights in plunging and swimming in water. It feeds chiefly on young shoots of trees, fruits, and other vegetable substances,

American Tapir (*Tapirus terrestris*).

but is ready to swallow almost anything that comes in its way. Pieces of wood, clay, and pebbles are often found in its stomach. It sometimes commits great ravages in cultivated grounds; a large herd of tapirs sallying forth from the forest by night, trampling and devouring all that they find in the fields. The tapir is a very powerful animal, and, protected by its thick hide, forces its way through the forest where almost no other quadruped can. When assailed by the jaguar it seeks to get rid of him by rushing through thick underwood, and if it can reach water is often successful by plunging in and diving. It is inoffensive, never attacking man, but when hard pressed by dogs makes a violent resistance, and inflicts severe bites. It is very easily tamed, and becomes extremely familiar; but its large size makes it a troublesome pet. Its hide is useful, and its flesh is eaten, although rather dry. The other two American species—viz. *T. bairdi* and *T. doerri*—are generally regarded as generically distinct from the rest, and have been termed *Elaomognathus*. The Malayan Tapir (*T. indicus*) is found in Malacca, Sumatra, &c. It is larger than the American tapir, and its proboscis is rather longer in proportion. The neck has no mane. The colour is glossy black, except the back, rump, and sides of the belly, which are white. The colours do not pass gradually one into another, but the line of separation is marked, giving the animal a very peculiar appearance. The habits of this species

are very similar to those of the American tapir, and it is equally capable of domestication. The young are striped and spotted as in that species.

The remains of tapirs have been found in Miocene and subsequent strata. In all about twelve species have been determined. Tapir-like animals are common in Eocene beds. *Lophiodon* appears to have been the precursor of the tapirs during the Eocene period. True tapirs are found in beds of an earlier age in Europe (Miocene) than in America (Post-Pliocene). Hence it has been argued that the tapir is an Old-World form which migrated to the New World, and ultimately established itself there upon a firmer footing.

Tapping is an operation frequently resorted to for the removal of fluid accumulations, particularly in the pleural and peritoneal cavities. It consists in introducing one end of a small tube into the cavity, with the least possible injury to the skin, and withdrawing by means of a vacuum as much of the fluid as is desired. Various contrivances (aspirators) have been used to effect this without allowing air to enter—the commonest form being that devised by Dr Potain. The fluid beneath the skin in general dropsy is removed by fine silver tubes (Sonthey's tubes) left in position for some hours or days; and the fluid in the spinal canal can be withdrawn by a sharp needle inserted between the vertebrae in the lumbar region. These instruments have done much for the certain diagnosis and safe treatment of fluid collections in various situations. Besides dropsical or inflammatory exudations in the pleura or peritoneum, similar collections in the joints can be thus dealt with; and cysts and abscesses, when deep-seated and obscure, can be recognised with certainty and sometimes cured. See DROPSY, PLEURISY, &c.

Taprobane. See CEYLON.

Tapti, a river of Bombay, rises in the Betul district of the Central Provinces, and flows 450 miles west through the Satpura uplands and the districts of Khandesh and Surat to the Gulf of Cambay, 17 miles below the town of Surat. Even small vessels of 40 to 50 tons burden cannot ascend higher than Surat. The port of Suvali, at the mouth, is now deserted, and the lower channels of the river are being silted up.

Tar. The nature of tar differs according to the raw material from which it is derived. In nearly all cases it is a thick, black, or dark-brown liquid of complex composition. The tars of commerce have a strong characteristic odour varying with their origin. When wood, coal, or shale is subjected to destructive distillation in close vessels there are produced (1) incondensable gases, (2) a liquid portion consisting of various substances soluble in water, and (3) another portion composed of bodies insoluble in water. This third or last portion is generally called tar. In former days wood-tar was used for much the same purposes as that for which the residual pitch derived from it is employed now. The time has come when any kind of tar is looked upon rather as a mother-liquor from which valuable chemical substances are obtained than as a material to be used by itself in the arts.

Wood-tar.—Different woods yield tars of a so far unlike nature. The tar from pine-wood is not the same as that from oak or beech. Most of the wood-tar produced in Europe is obtained from the Scots pine (*Pinus sylvestris*), but it is also got from other pines and from larch. Coniferous wood yields from 14 to 18 per cent. of tar, while from the wood of dicotyledonous trees of temperate regions only from 9 to 10 per cent. is obtained. Wood-tar is still made by the very old process of

burning wood in cone-shaped piles covered over with sufficient earth and turf to exclude air, of which just enough is admitted to promote combustion by means of apertures at the bottom where the pile is ignited. The pile stands on a clay floor, and it is fully a week before any tar is collected. By this rude process much charcoal, crude acetic acid, and other products are wasted; but these are now very often saved by distilling the wood in close vessels. Several forms of retorts or kilns are employed to make charcoal and at the same time to yield tar. One kind of kiln is in the shape of an oblong brick chamber, arched over, and with a floor formed into a sort of channel sloping from the middle of the chamber, where it is highest, to each of the end walls. Its internal size is 25 feet long, 12 feet wide, and 15 feet to top of arch. The chamber is closely filled with wood, the only place where a small space is left being where the flame or heat from the fire enters at one side. Air must be as far as possible excluded during the charring of the wood, which in a kiln of this kind may consist of stumps, branches, and any sort of odd pieces. The fire hearth, placed just outside the side wall of the chamber, has no grate, so as to prevent too much draught. As the tar is formed it runs down the right and left inclines of the channel, and at each end, by one branch of a two-way pipe, is led into a tar vessel, while the more volatile acetic acid and wood-spirit pass by the upper branch of the pipe into a condenser. Wood-tar contains (besides the tar proper) a large admixture of watery distillate, and gives on redistillation acetic (pyroligneous) acid, wood-spirit or methyl-alcohol, methyl-acetate, acetone, wood-cresote, and wood-naphtha, consisting of hydrocarbons very often containing methyl groups replacing hydrogen; also heavy oils and crystalline bodies not yet much investigated and that disappear in the pitch. Tar from some resinous woods contains oils resembling turpentine in composition. Before American petroleum became so cheap an oil of this kind was made in Norway and burned in paraffin-lamps.

In medicine tar and tar-ointment are used for cutaneous diseases (such as psoriasis), and much controversy arose as to the virtues of tar-water, regarded by Bishop Berkeley as almost a panacea. Tar-water was the watery liquor obtained when a quart of wood-tar and a quart of water had been well shaken together and allowed to settle. This Berkeley found was used, taken internally, as a preventive and palliative of smallpox in the American colonies. He tried it and found it exceedingly useful, he says, for consumption, fevers, ulcers, pleurisy, gravel, stomachic disorders, &c.; and on it bases his *Siris* or *Treatise concerning the Virtues of Tar-water*, a chain of philosophical reflections, which, as Professor Fraser says, connects tar-water with the throne of the Divine Ruler of the universe.

The use of tar or pitch for 'tarring and feathering' obnoxious persons, still understood to be practised in some parts of the United States in execution of mob-law, is of very ancient origin, dating apparently at least from the times of the Crusades. According to Rymer's *Foedera* and Hakluyt's *Voyages*, King Richard I. enacted for the royal navy that a thief or felon 'lawfully convicted, shal have his head shorne and boyling pitch poured vpon his head, and feathers or downe strawed upon the same, wherby he may be knownen.' Scarron (q.v.) was reported to have tarred and feathered his own person as a carnival disguise.

Coal-tar or *Gas-tar*.—In the making of gas for illumination the coal is distilled at a higher temperature than that used for the production of ordinary coke, the result being that the constituents of the tar from the two processes differ.

Gas-tar contains more benzole and other colour-making materials than coke-tar. See **COAL-TAR**.

Coke-oven Tar.—For long the recovery of the volatile products, such as tar and ammonia, given off during the conversion of coal into coke was neglected. Coke-ovens are, however, now constructed which, among other improvements, include the collection of the tar, the nature of which depends upon the temperature at which the coal is distilled. In the Jameson coke-oven the temperature is low at the point of destructive distillation, and consequently the tar produced contains paraffin and the higher phenols. On the other hand, the Simon-Carvès coke-oven, in which a high temperature is reached, produces a tar more resembling that obtained in coal-gas making. It is characterised by the presence of naphthaline and Anthracene (q.v.), and small quantities of benzole and carbolic acid.

Blast-furnace Tar.—In some cases the tar from iron blast-furnaces in which coal is used as fuel is now recovered. It is of an intermediate quality between the two kinds of coke-tar just noticed, but rather more resembling that produced at a high temperature.

Lignite or Brown Coal and Peat were distilled some years ago to yield tars. The former gave a considerable yield of butyry tar containing about 15 per cent. of paraffin. From the latter a tar was obtained, also yielding some paraffin.

Tara. See **TARO**.

Tara, HILL OF, an eminence (507 feet) in County Meath, 7 miles SSE. of Navan. Here prior to 560 is said to have stood the hall of the kings of Ireland; and here O'Connell (q.v.) held a monster meeting on 15th August 1843.

Tara Fern (*Pteridium esculentum*), a large bracken-like fern whose rhizome was one of the principal articles of food of the Maoris before the settlement of New Zealand by British colonists. The rhizome, about an inch in circumference, was cut in pieces, dried, and stacked. For use it was steeped in water, dried in the sun, and then roasted. Good flour was obtained from it by beating on a stone.

Taranaki (formerly New Plymouth), a provincial district of New Zealand, occupying the south-west corner of the North Island; area, 5732 sq. m., of which a great part is dense forest. The coast is lined with iron-sand and smelting has been tried though not very successfully. The soil and climate are good for rearing stock, and being well watered grass and root-crops are abundant. Pop. 62,000. Capital, New Plymouth; pop. (with suburbs) 14,000.

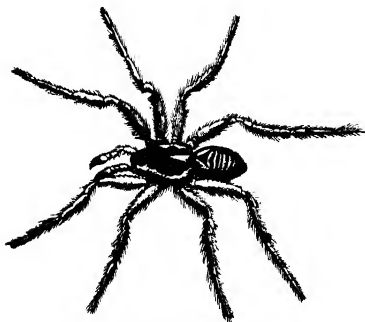

Tarantella, a rapid dance in triplet time, accelerating as it continues, and sometimes accompanied either with song or with tambourine and castanets. It is probably named after Taranto in Apulia, but has been curiously associated with 'tarantism,' a disease specially rampant in the 16th century, and falsely attributed to a bite of the Tarantula (q.v.) spider. The dance was popularly supposed to be a remedy.

Taranto (anc. *Tarentum*), a seaport of Southern Italy, in the province of Lecce, situated on a rocky islet between the Mare Grande or Gulf of Taranto and the Mare Piccolo, an extensive natural harbour on the east side of the town, 72 miles SSE. of Bari by rail. The harbour is sheltered by two small islands, San Paolo and San Pietro, the *Charades* of antiquity, and is closed by Cape San Vito on the south-east. The town is joined to the mainland by a six-arched bridge on the east side, and on the west by another, carrying a Byzantine aqueduct.

The principal buildings are a modernised cathedral dedicated to St Cataldo, a dubious 6th-century Irishman said to have been the first bishop of Tarentum, and a castle erected by Charles V. There is a very fine archaeological museum containing antiquities (principally vases and terracottas from tombs at Tarentum and elsewhere in Apulia, notably Canosa). The Mare Piccolo is still famous for its shell-fish, and a considerable portion of the population (1921, 103,807) finds employment in oyster and mussel fisheries. The honey and fruit are still famous also, but the chief importance of the town is as an arsenal and naval base, there being practically no commercial shipping.

The earliest habitation on the site was a terramara on the Scoglio del Tonno to the NW. of the town, exactly like those of the Po valley—apparently an isolated colony. The ancient Tarentum, founded by a body of Spartan emigrants about 708 B.C., grew to be the sovereign city of Magna Græcia, famous for its purple fisheries, potteries, wool manufactures, &c. Its 4th century coins are perhaps the finest the Greeks ever struck. A small part of an early Doric temple still exists (early 6th century B.C.), and other remains, including those of the city wall, and many tombs have been excavated. Here flourished about 400 B.C. the philosopher and geometer Archytas, under whom it became the centre of the Pythagorean sect. At the height of its greatness it insolently provoked a quarrel with Rome (281), was saved for a little by Pyrrhus, king of Epirus, but taken in 272, and retaken and punished severely in 209 for revolting to the side of Hannibal five years before. Under Augustus it was still essentially Greek, and was a favourite resort. Later it belonged to Byzantine, Saracen, and Norman masters, sharing the fortunes of the kingdom of Naples.

Tarantula, a name applied to various spiders, e.g. *Lycosa narbonensis*, a common South-European 'wolf-spider,' and *Eurypelma hentzi*, an American Avicularid. They give, like all spiders, a venomous bite, the seriousness of which is exaggerated. The name refers to the town Taranto where

Tarantula Spider, $\frac{3}{4}$ natural size.

Lycosid spiders are common. Unfortunately the generic name Tarantula belongs to an American genus of Pedipalpi, not spiders at all, but related to 'whip-scorpions.'

TARANTISM was a leaping or dancing mania, accompanied with gesticulations, contortions, and cries somewhat resembling those of St Vitus's Dance and other epidemic nervous diseases of the middle ages; but the affection differed from these in several respects, and was doubtless some not then recognised nervous malady, the symptoms of which are plainly those of hypochondriacal and

hysterical affections. The sufferers were subjected to extraordinary treatment, such as being buried up to the neck in earth. For the use of music and dancing, see TARANTELLA. Cases of tarantism relieved by dancing to music were reported from Asia Minor in 1911. Homœopathy uses a preparation of the spider's venom as a remedy for St Vitus's dance. See Hecker's *Epidemics of Middle Ages*.

Tarapacá, till 1883 the southernmost department of Peru, but annexed by Chile after the war. Area, 16,700 sq. m.; pop. 100,500. The country contains vast fields of nitrate of soda, as well as silver-mines and deposits of guano. Capital, Iquique (q.v.).

Tarare, a manufacturing town of France, in the dept. of Rhône, stands at the foot of Mont Tarare, 21 miles NW. of Lyons by rail. It manufactures muslins, tarlatans, silks, satins, plush, &c. Pop. 12,500.

Tarascon, a town and railway junction of France, in the Provencal department of Bouches-du-Rhône, 14 miles SW. of Avignon and connected with Beaucaire by a suspension bridge across the Rhône. King René's castle, now used as a prison, dates from 1400; and an old Gothic church is dedicated to St Martha, who here is said to have subdued a dragon called Tarasque. But Tarascon is chiefly famous through associations with the immortal Tartarin of Daude's creation. It has manufactures of woollens and silks, 'saucissons d'Ailes,' &c. Pop. 8300.

Tarawera. See NEW ZEALAND, Vol. VII. p. 487.

Taraxacum, a genus of Compositæ ranging from Novaya Zemlya to the Falkland Islands, including the Dandelion (q.v.).—**TARAXACUM**, or DANDELION-ROOT, is a tonic laxative in disorders of the liver.

Tarazona, an episcopal city of Spain, in the province of Saragossa, 20 miles S. of Tudela, on an affluent of the Ebro. Pop. 8300.

Tarbagatai, mountains, 10,000 feet high, in Russian Central Asia, on the frontier between Semipalatinsk (Cossack Republic) and Mongolian Zungaria.

Tarbes, a town in the south of France, capital of the department of Hautes Pyrénées, stands on the left bank of the Adour, 24½ miles by road ESE. of Pau and 12½ miles NW. of Lourdes (q.v.). There is a somewhat uninspiring cathedral, and a government arsenal, and the place is famed for its breed of light horses. Pop. (1921) 26,585. **Turba**, under the Romans, stood about 11 miles SE. of the present town. The bishopric is thought to date from the end of the 5th century. The town was in the hands of the English from 1360 to 1406. It is the birthplace of Barère, Gautier, and Foch.

Tardigrada (Lat. 'slow-paced'), a name given to the group or sub-order of mammals containing the two genera of Sloth (q.v.), remarkable for their sluggish movement and extraordinary tenacity of life under injury, starvation, or poison.

Tardigrada, or BEAR-ANIMALCULES, a group of animals of uncertain affinities. They appear to be degenerate Arthropoda, and show some resemblances to the mites and to the pycnogonids. They are of small size, a millimetre or less in length. They live in water, or on Sphagnum and other bog-mosses, but some have great power of resisting drought, and revive on being placed in water. In others the eggs have the same power. The body has a distinct head, but no abdomen, and is unsegmented. The animal moves about slowly by means of four pairs of very short, unjointed legs. Circulatory and respiratory organs seem to be absent, but the nervous system is well

developed. Eyes may be present. The tardigrades are hermaphrodite.

Tare, a number of species placed by some, along with the Lentil, in a genus *Ereum*, distinguished from *Vicia* (see *VERTCH*), to which it is oftener assigned, by a capitate stigma, downy all over. It is not supposed that the *Tare* of the New Testament has any affinity to these plants; it is doubtful what it is, but it seems not improbable that it is the *Darnel* (q.v.).

Tare and Tret, certain deductions usually made from the gross weight of goods. *Tare* is the weight of the box, cask, bag, or wrapping containing the goods; and the amount is obtained either by weighing the empty package itself, by taking an average of a few similar packages of equal size, or by mutually agreeing upon a certain proportion of the gross weight. The remainder is the *net weight*. Another deduction, at the rate of 4 lb. for every 104 lb., or $\frac{1}{26}$ th of the net weight, is then made, as an allowance for waste through dust, &c., and is called *tret*.

Tarentum. See *TARANTO*.

Target, in its modern sense, is the mark for aiming at in practising with cannon, rifle, bow, or the like. In its more ancient meaning a target or targe was a shield, circular in form, cut out of ox-hide, mounted on light but strong wood, and strengthened by bosses, spikes, &c. Of modern targets the simplest is that used for Archery (q.v.). Targets, as commonly thought of, are usually painted white and have a black 'bull's-eye' in the centre (varying in diameter according to the length of range), and three further rings called respectively 'inner,' 'middle,' and 'outer.' Frequently only the upper half of the 'bull's-eye' is visible, i.e. black. The accessories are a butt, artificially constructed or cut in the face of a hill, to catch stray shots; a marker's shot-proof cell, near the targets; and a range of such length as can be produced. Previous to the inauguration of the Wimbledon meeting in 1860 all targets were circular, and made of iron. From that year till 1873 they were square iron plates; but in 1874 targets of canvas and paper stretched on an iron frame were introduced, together with practice at objects moving at various rates of speed and at a greater or less distance, for which purpose a 'running-man target' was devised, consisting of a millboard figure running on wires, worked by the marker in the butt. There are also self-marking or automatic targets, constructed of several pieces, each of which when struck signals the fact; and disappearing targets, only visible to the firer for very short periods of time. For these and for field firing, targets take the form of flat wooden dummies shaped like men standing or kneeling. Black and brown head-and-shoulder silhouettes are the regular service targets, the bull's-eye variety having been largely discarded except for 'grouping' exercises. Dummies are also used as targets for field artillery practice. Heavy guns firing on a sea-range generally use a floating target, often a large timber framework lying at anchor or attached to buoys.

Targovica, or *TARGOWICZ*, a small town in Ukraine, was the scene (May 1792) of a plot by five Polish nobles to overthrow the constitution of 1791. See *POLAND*.

Targum (Assyr. *ragānu*, 'to speak,' whence *targumānu*, 'speaker'), the general term for the Aramaic versions—often paraphrases—of the Old Testament, which became necessary when, after and perhaps during the Babylonian Exile, Hebrew began to die out as the popular language, and was supplanted by Aramaic (see *ARAMAIC*).

* But see p. 1076, *Hebr. & Engl. Lex.*, Oxf., 1906.

The origin of the Targum itself is shrouded in mystery. The first signs of it—as an already fixed institution—have been found by some in Nehemiah, viii. 8, and according to tradition Ezra and his coadjutors were its original founders. However this be, there can be no doubt that its beginnings belong to a comparatively early period. The *Mishna* (q.v.) contains a number of strict injunctions respecting it, and also respecting a certain guild of Meturgemans (whence 'dragoman') or interpreters, who had sprung up as professional followers of those learned men who, at a previous period, had volunteered their services in the translation and paraphrastic interpretation, both activities being implied by the term. At first, and indeed for many centuries, the Targum was not committed to writing, for the same reason that the 'Oral Law' or Halakha itself was not at first intended ever to become fixed as a code for all times. In the course of time, however, both had to yield to circumstances, and their being written down was considered preferable to their being utterly forgotten, of which there was no small danger. Yet a small portion only of the immense mass of oral Targums that must have been produced has survived. All that is now extant are three distinct Targums on the Pentateuch, a Targum on the Prophets, Targums on the Hagiographa—viz. on Psalms, Job, Proverbs, the five 'Megilloth' (Song of Songs, Ruth, Lamentations, Esther, Ecclesiastes), another Targum on Esther, one on Chronicles, one on Daniel, and one on the apocryphal pieces of Esther. The most important of the three Pentateuch Targums is the one named after Onkelos, probably a corruption of Aqylas (Aquila, a proselyte, one of Gamaliel's pupils), whose Greek version had become so popular that this Aramaic version was honoured with being called after it. This Targum seems to have been originally produced among the scholars of R. Akiba between 150 and 200 A.D. in Palestine, and sent to Babylonia, where it was more needed; wherefore it is called *Babli*. Here it was probably edited about 300, and afterwards vowelised in the Babylonian method. Subsequently vowelised in the Palestinian method, it spread from Palestine over the world. It is an excellent translation for the people, and adheres more closely to the Masoretic text than any other ancient translation. It is useful for the exegete, the linguist, and the antiquary.

Two other Targums on the Pentateuch have hitherto been known as Targum Jonathan ben Uzziel and Targum Jerushalmi. They are of Palestinian or Syrian growth. Jerushalmi is fragmentary, and appears to be a Hagadic supplement to Onkelos. The Pseudo-Jonathan, by its maturer angelology, its abbreviations, and other signs, appears to be a later recension of the Jerushalmi. It cannot well have been composed before 750. As a version this Targum is of small importance; but it is valuable as a storehouse of allegories, parables, sagas, and the like popular poetry of its time. Its language and grammar are exceedingly corrupt; it abounds, moreover, with foreign—Greek, Latin, Persian, and Arabic—terms. It mentions Constantinople (Numbers, xxiv. 19, 24); and names Khadija (or Ayesha) and Fatima (Genesis, xxi. 21). Its general use lies more in the direction of Jewish literature itself, as well as of archaeology and antiquities of the early Christian centuries, than in that of a mere direct interpretation of the Bible text. The Targum on the Prophets is generally and erroneously ascribed to Jonathan ben Uzziel, an eminent scholar of Hillel the Elder; the fact being that, except for one spurious Talmudical passage, in which mention is made of his having translated the Prophets, this

Targum is everywhere else, from the Talmud down to the authorities of the 10th century, ascribed to one R. Joseph, president of the Babylonian school of Pumbeditha about 322. This Targum, while tolerably literal in the first—the historical—books, gradually becomes a frame for Haggada, which it introduces at every turn and at great lengths. It is considerably interpolated, containing historical bits disguised, or rather typified, lyrical pieces of some poetic value, and much Messianic lore. In language and general manner it resembles Onkelos, which evidently lay before the author.

Joseph the Blind, to whom the foregoing Targum is ascribed, is the reputed author of Targums on the Hagiographa. Several centuries lie between him and them, their date being approximately between 800 and 1000. Certain distinctions between the different books must further be made. The Targums on Psalms, Job, and Proverbs were probably contemporaneous compositions due to private enterprise in Syria. The two former are made more paraphrastic than the last, which resembles closely the Syriac version. The paraphrase on the five 'Megilloth' mentions the Mohammedans, and is of later date; probably one man's work. It is principally a collection of more or less poetical fancies, traditions, and legends, to which the single verse in hand merely seems to furnish the keynote. Its dialect lies somewhat between the East and West Aramaic. The Targum on the Book of Chronicles—almost unknown until it was printed in the 17th century—also belongs to a late period, and was probably composed in Palestine. There are some useful philological, historical, and chiefly geographical hints to be gleaned from it, but nothing more; least of all can it be used exegetically. A Persian version of a Targum on Daniel (unedited) is all that has been discovered on that book as yet. It was probably composed in the 12th century, the influence of the early Crusades being plainly visible in it. On the paraphrase of the apocryphal pieces of Esther we shall not dwell here, any more than on the scanty fragments of a 'Palestinian Targum' that are found either interspersed in the general (Babylonian) Targum, or as independent pieces. It seems probable that more of this Palestinian version will come to light some day, as authorities of a few centuries back still quote from it rather largely. At present, however, their quotations are nearly all that is known. By 900 in Africa and Spain the Targum had begun to be disused in public, Arabic or the national language being substituted. In Yemen the Aramaic Targum is still used in the ancient manner, the meturgeman standing beside the reader and rendering verse by verse. In London the prophetic lesson (Jer. viii. 13—ix. 23) is still read with a Spanish Targum in the Sefardic synagogues on the Fast of Ab.

The Targum of Onkelos was first printed unvowelled in Bologna, 1482; vowelled, Lisbon, 1491; more or less incorrectly in the Bomberg Rabbinical Bible of Venice (1518) and in subsequent editions; the Complutensian Polyglot (1517); the Biblia Regia of Antwerp (1569); and Walton's Polyglot (Lond. 1657). Buxtorf's edition (1618-19) is vitiated by attempts to conform it to biblical Aramaic. The Sabionetta edition (1657) is the best till Abr. Berliner's reproduction of this (Berlin, 1844), with an exhaustive essay. The Targum on the Prophets appears in the Bomberg, Complutensian, Antwerp, Buxtorf, and Walton Bibles. It is edited by Paul de Lagarde (Lein. 1872). He edited the Targum on the Hagiographa (1873). See Frankel, *Zu d. Targum der Propheten* (Breitlan, 1872); Pauli, *Chaldee Paraphrase on Isaiah* (Lond. 1872); the *Targum of Onkelos and Jonathan on the Pentateuch* (1862 and 1865), by Etheridge.

The late Chief Rabbi, Dr N. M. Adler, composed a valuable commentary on the Targum on the Pentateuch, called *Nethinah lap-Cer*. This is printed in certain Rabbinic Bibles, e.g. Vilna, 1886.

See the articles (with bibliographies) by I. Abrahams (Hastings, *E.R.E.*, xii. 202); F. C. Burkitt (in article 'Texts and Versions,' *Ency. Bibl.*, iv. 5028); J. F. Stenning (*Ency. Br.*, xxvi. 419); W. Baehner (*Jew. Ency.*, xii. 57); T. Walker (Hastings, *Dict. Bible*, 1902, iv. 678); W. Oosterley (Hastings, *Dict. Bible*, 1909, p. 893), also in Oosterley and Box, *Religion and Worship of the Syn.*, ed. 1911, p. 46.

Tarifa, the southernmost town on the continent of Europe, is a seaport of Spain, in the province of Cádiz in Andalusia, and is situated 21 miles SW. of Gibraltar. The town is still quite Moorish in aspect, and retains its alcázar and battlemented Arab walls. A causeway connects it with a small island, on which are some powerful fortifications and a lighthouse, 135 feet above sea-level. Tunny and anchovy fishing is and has been since Roman times the principal occupation of the inhabitants, but the preparation of leather is also carried on, and there is a trade in sweet oranges. Tarifa, called Julia Jozza by Strabo, was occupied in 710 A.D. by the pioneers of the Moorish invasion, under Tarif Abū-Zor'a, whence it obtained its Arabic name of Jazīret-Tarif (Tarif's island). It was taken from the Moslems, after an obstinate siege, in 1292, by Sancho IV. of Castile, and its first Spanish governor was Alonzo Perez du Guzman, celebrated in the *Romancero* for his valiant defence of the town against the besieging Moors in 1294. During the Peninsular war Tarifa was successfully defended by Gough with 1800 British troops and 700 Spaniards against a besieging army of 10,000 French (December 1811 to January 1812). Pop. 12,000.

Tariff (from an Arabic word for notification), a table or catalogue, generally drawn up in alphabetical order, of the duties, drawbacks, bounties, &c., charged or allowed on different kinds of merchandise, as settled by authority, or agreed to between different states. The principles of the tariffs of different countries depend on their respective commercial policy, and on the fluctuating interests and wants of the community. The duties may be prohibitory, retaliatory, countervailing, or differential, and may be designed to bring in revenue or to afford protection without definite thought of revenue. A *single-line* tariff, usually a revenue tariff, consists of one schedule of duties to be applied irrespective of country or conditions. A *double-line* (or *multiple*) tariff consists of a schedule of two (or more) rates for each article. Double-line tariffs are: (a) *general conventional* (as in Germany), in which a general rate of duty is fixed by the legislature, while a second or conventional rate results from the operation of commercial conventions and 'most-favoured-nation' clauses; (b) *maximum and minimum* (as in the United States), in which two rates, a higher and a lower, are fixed by the legislature, the lower being applied to favoured countries. These broad distinctions are apt to be blurred in particular cases. Duties may be: (a) *ad valorem*, i.e. assessed as a percentage of the value of the article; (b) *specific*, i.e. based on some physical feature of the object, weight, length, specific gravity, &c.; (c) a combination of these two. A feature of modern tariff schedules is the tendency to specialisation of grades and qualities, and the preference for specific duties as being more satisfactory in practice. See T. E. G. Gregory, *Tariffs: a Study in Method* (1921). See CUSTOMS DUTIES, FREE TRADE, PROTECTION.

Tariff Reform, the name applied to the movement for imperial preference inaugurated in 1903 by Mr Joseph Chamberlain (q.v.). See CORN LAWS, FREE TRADE, PROTECTION.

Tarik. See GIBRALTAR.

Tarim River. See TURKESTAN (EASTERN); and ASIA.

Tarlatan, a thin, gauze-like fabric of cotton, used for ladies' ball-dresses, &c. It is either finished white or dyed or printed in colours. Tarare is the chief centre of this manufacture; the Swiss tarlatans are inferior.

Tarlton, RICHARD (d. 1588), a famous clown of Queen Elizabeth's day, on whom was fathered one of the best-known jest-books (q.v.).

Tarn, a dept. in the south of France, bounded on the N. by the depts. of Aveyron and Tarn-et-Garonne, receives its name from the river Tarn, an affluent of the Garonne. Area, 2231 sq. m.; pop. (1881) 359,223; (1921) 295,588. The surface is in general elevated, and in the south and south-east are the Montagne Noire and the Lacanne branches of the Cévennes. Wooded mountains, vine-clad hills, beautiful valleys, and fertile or grass-producing tracts are the principal features of the landscape. A considerable part of the surface is covered with forests, chiefly of oak and beech. The dept. is for the most part agricultural, grain, wine, fruit, potatoes, chestnuts, and cattle being amongst the chief produce. Coal is mined; and wool-spinning, silk-spinning, dyeing, the making of steel goods, glass, and pottery are local industries. Tarn is divided into four arrondissements—Albi, Castres, Gaillac, and Lavaur; Albi is the capital.

Tarn-et-Garonne, a small dept. in the south of France, bounded on the S.E. by the dept. of Tarn. Area, 1440 sq. m.; pop. (1881) 217,056; (1921) 159,559. The principal river is the Garonne, with its affluents the Tarn and Aveyron. The surface is largely occupied by plateaus, about 1000 feet in average altitude; the highest hills do not rise above 1600 feet. The climate is temperate. Cereals are raised, also wine, fruit, hemp, &c. Hydraulic lime, calcium phosphate, and barytes are worked, there is some copper-smelting and some manufactures of straw hats, silk, and paper. The dept. is divided into the three arrondissements of Montauban, Castelsarrasin, and Moissac; Montauban is the capital.

Tarnopol, a town of Eastern Galicia, on the Serech, 80 miles ESE. of Lemberg by rail. Pop. 30,900.

Tarnow, a trading town of Polish Galicia, 50 miles E. of Cracow by rail. It has a theological college and a fine cathedral. Pop. 36,000.

Taro (*Colocasia antiquorum*), a plant of the Araceae, of a genus akin to the Cocco (q.v.) or Eddoes, cultivated for its roots, which are a principal article of food in the South Sea Islands. They are washed to take away their acidity, and cooked in the same way as bread-fruit; they may also be boiled or made into a pudding. A pleasant flour is made of taro. The plant has no stalk; broad, heart-shaped leaves spring from the root; and the flower is produced in a spathe. The leaves are used as spinach.

Tarots. See CARDS.

Tarpan. See HORSE.

Tarpsulin, strong linen, hempen, jute, or cotton cloth, coated with tar or pitch or other material to render it waterproof.

Tarpeian Rock. See CAPITOL.

Tarpon (*Megalops atlanticus*), an American food-fish belonging to the Clupeidae, much sought after by sportsmen, is common in the warmer Atlantic waters and off the shores of the Gulf states, and attains a length of 6 feet. It is sometimes called Jew-fish.

Tarquinii. See CORNETO.

Tarquininus, the family name of two kings of Rome, derived from the Etruscan city of Tarquinii—and doubtless implying the domination of

that city over a district south of the Tiber. The first, Lucius Tarquinus Priscus, is said to have reigned at Rome 616-578 B.C., and to have considerably modified the constitution, and to have begun the Servian agger and the Circus Maximus.—Lucius Tarquinus Superbus (534-510), the seventh and last king of Rome, was a capable but intolerable despot, the chief events of whose reign are given at ROME. See LUCRETIA.

Tarragon, an aromatic plant (*Artemisia Dracunculus*; see WORMWOOD) used for flavouring vinegar, sauces, &c.

Tarragona, a seaport of Spain, chief city of the modern province of Tarragona, situated on the Mediterranean shore, at the mouth of the Francolí, 60 miles W. of Barcelona by rail. The upper and older town is irregular and dirty, and is girdled with ramparts; the lower is regular and open, and defended by two forts. Tarragona is the seat of a bishop. The Gothic cathedral, one of the finest of its kind in Spain, dates from about 1120. There are some anchovy, tunny, and sardine fisheries, and a few unimportant manufactures. Liqueur is made by the exiled monks of the Grande Chartreuse (q.v.). A considerable miscellaneous trade is done through the harbour at the S.W. of the new town. Pop. (1920) 27,883. Tarragona, the Roman *Tarraco*, was the capital of the Roman province of *Tarraconensis*. Among the Roman antiquities are the remains of an amphitheatre, which has been used as a quarry; a magnificent aqueduct, 96 feet high and 700 feet long; and near the town the Tower of the Scipios, much decayed. Tarragona was taken by storm by the French under Suchet in 1811, but in August 1813 its fortifications were blown up by him when unable longer to hold out against the English.

Tarrytown, a village of New York, on the Hudson, 21 miles by rail N. of New York City. It has some manufactures. Close by Major André was captured in 1780; and two miles to the south Washington Irving spent his last years, and there lies buried. Pop. 6000.

Tarshish, probably the same as *Tartessus*, which is the Latin form for the Greek name of a city and emporium of the Phoenicians in Spain, near the mouth of the Guadalquivir, but used of the whole region—subsequently known as Andalusia (q.v.). Tarshish is frequently mentioned in the Bible. Speaking of Tyre, Ezekiel (xxvii. 12) says—'Tarshish was thy merchant by reason of the multitude of all kinds of riches'; notably there were here great fisheries of tunny and murena, and rich mines of silver and other metals. Less likely are the views that Tarshish was simply Tarsus (q.v.), or else a part of Yemen, near Ophir (q.v.). The site of Tartessus was explored in 1911 and 1919-22 by Professor Adolf Schulten, who ascribes the origin (in the 3d millennium B.C.) and early importance of Tartessus to Cretan merchants, and its distinction (6th century B.C.) to the Carthaginians. See A. Schulten, *Tartessos* (Hamburg, 1922).

Tarsia-work. See INLAYING.

Tarsier (Tarsius). See LEMUR.

Tarsipes, a small Australian honey-sucking marsupial, of the family Phalangeridae, about the size of a mouse. See MARSUPIALS, PHALANGER.

Tarsus, anciently chief city of Cilicia, and one of the most important in Asia Minor, on the river Cydnus, 12 miles from the sea, in the midst of a productive plain. It was a great emporium for the traffic carried on between Syria, Egypt, and the central region of Asia Minor. In the time of the Romans two great roads led from Tarsus, one north across the Taurus by the 'Cilician Gates,'

and the other east to Antioch by the 'Amanian' and 'Syrian Gates.' Tarsus, which was sacred to Baal Tars, may have originated in an Ionian colony. It fell to the Assyrian Shalmaneser about 830 B.C., and joined unsuccessfully in a revolt in 696. In the *Anabasis* of Xenophon it figures as a wealthy and populous city, ruled by a prince tributary to Persia. In the time of Alexander the Great it was governed by a Persian satrap; it next passed under the dominion of the Seleucids, and finally became the capital of the Roman province of Cilicia (66 B.C.). At Tarsus Antony received Cleopatra, when, as Aphrodite, she sailed up the Cydnus, with magnificent luxury. Under the early Roman emperors Tarsus was as renowned for its culture as for its commerce, Strabo placing it, in respect to its zeal for learning, above even Athens and Alexandria. The natives were vain and luxurious; a Moslem general estimated their number at 100,000. Weaving goats' hair was the staple manufacture. It was the birthplace of the apostle Paul (q.v.), who received the greater part of his education here; the Stoic Antipater and the philosopher Athenodorus were also natives, and here the Emperor Julian was buried. Gradually, during the confusions that accompanied the decline of the Roman and Byzantine power, it came into the hands of the Turks, and fell into comparative decay; but even yet this modern, squalid, and ruinous city, under the name of *Tarso* or *Tersus*, has a permanent population of 7000, and a pop. of 30,000 in winter, and exports corn, cotton, wool, gall-nuts, wax, goats' hair, skins, hides, &c.

Tartan. See HIGHLANDS.

Tartar. a mixture of bitartrate of potash and tartrate of lime, is a deposit formed from wine, and known in its crude form as Argol (q.v.). The name, given by the alchemists, is usually referred to Gr. *tartaros*; but some derive it from Arab. *dard*, 'dregs.' See CREAM OF TARTAR, TARTARIC ACID. For tartar on the teeth, see DENTISTRY; for tartar emetic, ANTIMONY.

Tartarian Lamb. See BAROMETZ.

Tartaric Acid. $C_4H_4(OH)_2(COOH)_2$, exists free or in combination with bases in the fruits and juices of many plants. In the rowan, grape, and pine-apple it gives a subacid flavour. The commercial source is *tartar*, or argol, an impure cream of tartar deposited in wine vats. This is boiled with chalk, and the insoluble tartrate of lime is removed by straining. On treatment with sulphuric acid and purification, tartaric acid is obtained in the form of large transparent, prismatic crystals, which are readily soluble in water. They possess a pleasant acid taste, and the solution reddens litmus. When rubbed in the dark the crystals become luminous. When tartaric acid is heated it melts, forming the isomeric pyro-tartaric acid, and by further heating it is broken up into a number of bodies, formic acid, acetone, and carbonic acid being among the number.

Besides the tartaric acid of commerce there are others, isomeric with the above, known to chemists. These differ mainly in the power of rotating the plane of Polarisation (q.v.) of light to the right or the left. The ordinary acid rotates it to the right, and another rotates it to the left, so that when mixed in equal proportions and dissolved the solution has no action on polarised light at all. Such a compound exists in nature, and is known as *racemic acid*. It gave rise to many important researches and discoveries, owing to its similarity to tartaric acid, except in its being inactive to polarised light. To Pasteur is due the above explanation of its peculiar behaviour. Tartaric acid is largely used in dyeing

and calico-printing, and in the manufacture of aerated waters and confections. Being a dibasic acid (see ACIDS), it forms a large number of salts, many of which are important. *Bitartrate of potash*, or *cream of tartar*, $KHC_4H_4O_6$, is obtained by purifying the crude argol by crystallisation. It is used, along with baking soda, by housewives, as a baking powder. Medicinally it is a useful purgative, and is a favourite domestic remedy for clearing the blood in spring-time. *Tartarated iron* or *tartrate of iron and potash* is a mild tonic, which, when dissolved in sherry, constitutes iron wine. *Tartrate of potash and antimony*, or *tartar emetic*, $KSbOC_4H_4O_6$, has been long used in medicine, in doses of $\frac{1}{2}$ to $\frac{1}{4}$ of a grain; it is a powerful sudorific, but in larger doses, 1 to 3 grains, it acts as an emetic. It has gained considerable notoriety through being employed in several famous poisoning cases which have come before the public. It should never be in unskilful hands, as $\frac{1}{2}$ grain has proved fatal to a child, and 2 grains in one case at least were fatal to an adult.

Tartars. See TATARS.

Tartarus, according to Homer, is a deep and sunless abyss, as far below Hades as earth is below heaven, and closed in by iron gates. Into Tartarus Zeus hurled those who rebelled against his authority, as Kronos and the Titans. Afterwards the name was employed sometimes as synonymous with Hades or the under-world generally, but more frequently for the place of damnation where the wicked were punished after death. See HELL.

Tartary. See TATARS.

Tartessus. See TARSHISH.

Tartini, GIUSEPPE (1692-1770), a celebrated Italian musician and composer, born at Pirano in Istria. At Padua he studied law, but gave it up for music and fencing. Having secretly married the niece of the Archbishop of Padua, he had to take refuge in a monastery at Assisi, where he became a proficient on the violin. In 1721 he was allowed to rejoin his wife, and return to Padua, where he was appointed solo violinist in the chapel of San Antonio, while seven years later he opened his famous school of violin-playing at Padua. He has been described as 'the greatest scientific and practical violinist of his day,' while of his numerous compositions the best known is the sonata, *Il Trillo del Diavolo*. He was the author of *A Treatise on Music*, and was the discoverer of the so-called grave harmonics, or third or combination sounds in sounding double stops.

Tartu. See DORPAT.

Tartuffe, the name of the chief character in Molière's most celebrated comedy, which has become a synonym in all languages for a hypocritical pretender to religion. See MOLIERE.

Tarudant, capital of the Moorish province of Sus, on the Sus, 40 miles from the sea; pop. 8500.

Tashkand, or TASHKENT, once the capital of Russian Turkestan, now the largest town of Uzbekistan (41° 20' N., 69° 18' E.), is watered by the Chirchik, which joins the Sir Darya about 50 miles to the SW. It consists of an ancient walled city and a new Russian quarter with broad streets bordered by canals and avenues of trees. Notable features are the university (1919), a fort, Russian schools of all grades, an observatory, library, and museum, and several learned societies (geographical, Eastern studies, &c.). It is connected with the European system of telegraphs, and by rail with Orenburg (1210 miles; since 1904) and the Caspian (1175 miles; since 1897). Tashkand has orchards and vineyards, and is a centre for Kalnuik wool. The Russian town has numerous industries (cotton-mills, tobacco factories, flour-

mills, &c.); the natives make metal, leather, and other goods. Pop. 245,000—55,000 in the Russian town, the rest mostly Sarts, Uzbegs, and Kirghiz. Tashkend was in 1810 conquered by Khokand, and since 1868 has been Russian. See TURKESTAN.

Tasmania, the only State of the Australian Commonwealth which lies apart from the mainland, is an island in the Southern Ocean, situated approximately between lats. 41° and 44° S. and longs. 144° and 149° E. Its greatest length and greatest breadth are each about 200 miles, and its area is 24,330 square miles. It is divided from Australia proper by Bass Straits, a channel about 150 miles wide, and the State includes the islands in the straits as far north as Kent's Group, about 39½° S., making its area up to 26,215 square miles.

The main island was discovered in 1642 by Abel Tasman, a Dutch voyager whom the governor of Batavia had commissioned to explore the Southern Ocean in the hope of discovering a rumoured southern continent. Tasman seems to have struck the coast somewhere near Macquarie Harbour, rounded the southern end, vainly attempted to explore Blackman's Bay (near which a sailor, swimming ashore, hoisted the Dutch flag), and left the coast almost opposite the point at which he had reached it, going thence eastwards to New Zealand. He named his discovery Van Diemen's Land, after the governor who had sent him out. One hundred and thirty years later a Frenchman, Marion du Fresne, followed almost exactly in Tasman's tracks, and effected a landing (not without attack from the aborigines) on the shores of Marion Bay. Next year the first Englishman, Tobias Furneaux, Cook's second-in-command on his second voyage, explored the southern shores confusedly, and misplaced many of Tasman's names.—Cook, who anchored there in 1777, acquiescing in Furneaux's mistakes. At this time and for some years afterwards the shores thus visited were believed to be a part of the mainland; but in 1798 Matthew Flinders (q.v.) and George Bass completely circumnavigated the island. French navigators, for some reason, were especially attracted by it; La Pérouse in 1785 was particularly ordered to explore it, and may have done so; D'Entrecasteaux in 1792-93 made careful and excellent surveys of the south-eastern corner, and Baudin's expedition in 1802 surveyed the whole coast line except a strip on the west. This attention naturally excited the suspicions of the English authorities in New South Wales, and early in 1803 hasty settlements were made at the mouths of the two chief rivers—the Derwent on the south, and the Tamar on the north; within a year or two both these were abandoned, and the final town-centres were established at Hobart and Launceston. For a short time each settlement had its own government; but Macquarie in 1813 appointed Colonel Davey lieutenant-governor of the whole island, and in 1825 the British parliament reduced the control of New South Wales to a shadow.

Settlement in the island proceeded more slowly than on the mainland, and on different lines. The Tasmanian aborigines, a less advanced race than the Australian, remained savage and hostile to the last (probably because they were from the first less tactfully treated), and a remnant was deported during the thirties to Flinders Island in the straits. The convict element in the settlements was both more prominent and worse in character, because it consisted of 'colonially convicted' prisoners—i.e. those who had committed fresh crimes after their arrival in New South Wales; hence escaped convicts who took to bushranging were exceptionally inhuman. The worst characters were isolated in a special settlement, at first at Macquarie Harbour on the west coast, afterwards at Port Arthur in

Tasman's Peninsula, which could be reached overland only across an extremely narrow neck of land, and was therefore a very safe prison. Governor Arthur (1824-36) maintained that free settlement must be subordinated to the interest of the convict prisons; though his successor, Sir John Franklin, attempted to encourage the free element, the next two governors were elected for their knowledge of convictism, and the abolition of transportation to the Australian mainland in 1840 greatly increased the number sent to Tasmania. It was not till 1852 that the British government agreed to send no more convicts anywhere east of the Bight; and this promise opened the way for the constitution of Tasmania as a self-governing colony—a promotion marked by the adoption of the present name, since up to that date the island had been always called by the name Tasman gave it. Thenceforth the little colony pursued a career just like those of its larger neighbours, developing agricultural settlement and orchards in the river-valleys, breeding sheep of high quality on the uplands, and from 1871 onwards discovering great mineral wealth, especially in the previously neglected north-west. In 1901 the colony became a State of the Commonwealth, receiving exceptional treatment at first by the concession of more representation than its population justified, afterwards by a series of special money-grants.

Geography.—The island is both geographically and geologically an outlier of the mainland, the long ridges of the eastern Australian tableland being traceable southwards through the island-groups of Bass Strait into Tasmania itself. A 300-feet elevation of the sea-bed would re-establish land-connection with Victoria. The tableland has been much worn away by river action, its exposure to the heavy rainfall of the 'roaring forties' both denuding and incising it severely. The central plateau, which carries on its surface several large lakes, is a triangular area about 50 miles in the side, and falls steeply to the valleys of the Tamar and Derwent tributaries in terraces, called 'bluffs' in the north and 'tiers' elsewhere. The plateau itself is also dissected by rivers, which have cut themselves deep gorges almost from the point at which they leave their parent lakes. Outside it there is practically no level ground in the island, though a region of comparatively low foothills stretches along the north coast from the Tamar to the Forth. The rest is occupied by knots of rugged hills: the north-eastern, delimited by the Tamar and South Esk, culminates in Mount Barrow (4664 feet) and Ben Lomond (whose highest point is Legge's Peak, 5160 feet); the south-eastern, whose highest hill is St Paul's Dome (3368 feet), lies east of the Jordan and Macquarie rivers; while the whole western area—nearly one-third—of the island is a tangle of difficult and as yet scarcely known ranges intersected by the many tributaries of the Arthur, Pieman, Gordon, and Huon. Cradle Mountain (5069 feet), the second highest in Tasmania, is on the line between this tangle and the central plateau; several others, including Mount Wellington behind Hobart, pass 4000 feet; but the chief interest of the western ranges centres on the highly mineralised district between Macquarie Harbour and the north coast.

The chief rivers are the Derwent (107 miles) and Tamar (160 miles); the latter river for the greater part of its course is known as the South Esk, the name 'Tamar' properly applying only to the 40 miles of navigable estuary. The Huon is also over 100 miles long, but the greater part of its course lies in unused country. The mass of settlement lies either in the basins of the two principal rivers or among the foothills of the north coast. Hobart, with 53,740 inhabitants, and Launceston, with about

25,000, are the only towns of importance; but Devonport on the north coast and a couple of mining townships in the west approach the 5000 mark.

Other notable physical features are the lakes and the island groups of Bass Straits. With the exception of Lake St Clair (9500 acres, 550 feet deep), which lies among high hills, all the big lakes are shallow depressions in the central plateau, and most drain to the Derwent; the Great Lake, though 28,400 acres in area, is barely 20 feet deep. Several are now well stocked with English trout, which in the Great Lake are said to have been altered by gross feeding into the bull trout form. Of the islands, the Kent and Flinders groups represent a former connection with Victoria, from Wilson's Promontory to Cape Portland, by a ridge which continues through Ben Lomond to Tasman's Peninsula; King Island and the Hunter group are relics of a similar connection between the Otway ranges and Cape Grim, which continues through Cradle Mountain to Mount Wellington and the Huon ranges. In the early days these islands were the resort of whalers, nowadays they are merely detached settlements sharing the interests of their larger neighbour. Among the many small islands off the ocean girt coasts, two—Burni Island in Storm Bay, and Maria Island above Tasman Peninsula—deserve mention for their size; otherwise they have no separate interest, though Maria Island was the scene of a risky experiment in silkworm-culture.

Although geologically homogeneous, the mountainous area which constitutes most of Tasmania is divided into two well-marked and very distinct sections. Like the neighbouring mainland, the island gets its weather mainly from the west, where the 'roaring forties' provide a steady supply of moisture. Consequently the eastern hills, which receive the winds only after they have been drained of their load, are comparatively dry, and their vegetation and products approximate to those of southern Victoria. The moderate rainfall (averaging 22-30 inches) nourishes forests of eucalyptus, banksia, and similar trees. The western ranges are hid under a very different kind of forest—'pines' (*Athrotaxis* and *Dacrydium*), beeches (*Nothofagus*), and sassafras furnishing the taller timber, with an almost impenetrable undergrowth of tea-tree, tree-ferns, and *Bauera* scrub that has been a principal factor in defeating many attempts to explore the region. The excessive rainfall (80 to 117 inches—'over three yards of rain,' say the few settlers there) which nourishes this enormous plant-growth also swells the rivers, and makes of the central lakes a series of inexhaustible reservoirs whose value is at last being utilised.

Geology.—Owing to the ruggedness and remoteness from settlement of a great part of the island's area, its geology has been only approximately worked out. Traces of the Archean (supposedly Algonkian) foundation of the tableland are found all along long. 146°—at Port Davey in the south, in the King William and Denison Ranges and the Collingwood valley in the centre, and in the Forth valley and near Rocky Cape in the north. Cambrian sandstones appear slightly to the east, near Latrobe in the north and near Mount Field West in the centre—both about long. 146° 30'. The north and north-eastern coastal district are largely Ordovician, and the west coast ranges Silurian (the massive conglomerates of the north-west, once considered Devonian, are now dated further back). Devonian granites are exposed along long. 148° as far south as Maria Island, and seem responsible for the great tin-fields of Zeehan, Mount Hemmiskirk, and Mount Bischoff in the west, and of Ben Lomond and the Blue Tier in the east. The Mount Lyell rocks may be Devonian or earlier. South-eastern

Tasmania is predominantly Permo-carboniferous, and coal-beds of that age are mined in the Mersey valley west of Launceston, and near Port Cygnet below Hobart. A much better quality of coal, mined along the upper valley of the South Esk, is variously attributed to upper Carboniferous and to Mesozoic series. The former seems more probable, the Mesozoic age being represented in Tasmania only by some variegated sandstones in the Hobart district, and by the great sheet of dolerites and diabases which almost covers the central plateau, preserving it from the extreme dissection which has been the fate of most of the great tableland. Mount Wellington is a fragment of this sheet. Tertiary rocks cannot be subdivided as in Europe; the lowest seem to be the marine fossiliferous beds at Table Cape on the north coast, in which occurs a very early marsupial; above them come the lake deposits of the Tamar valley and the alluvial tin-bearing sands and gravels of the north-east; then come sheets of basalt, usually olive, well displayed in the promontory of Circular Head; above these sheets come more gravel drifts, and the close of the Tertiary period was marked by a glacial epoch, of which many traces are left, between Macquarie Harbour and the central plateau. The same district shows glacial deposits of late Pliocene age.

Aborigines.—The aborigines of Tasmania, though believed by some writers to be Melanesians, or unaltered Australians, are now almost certainly classed as Negritos. It is still uncertain—and will probably always remain so—whether they were driven southwards through and out of Australia by the invading Dravidians, who are represented by the present 'blackfellows,' or whether, as Huxley suggested, they reached Tasmania from New Caledonia by traversing lands now sunk below the Pacific along Australia's eastern shores. At any rate they seem to have left no trace of their passage through Australia itself, unless the peculiar shape of the cranial vault in certain South Australian tribes betokens intermarriage with women of the Tasmanian type. The race is quite extinct, and we depend for first-hand information about it on numerous casual accounts by unskilled observers, strengthened with a very few careful observations made by the one or two Europeans who took any trouble to know them. With these inadequate sources of information, however, H. Ling Roth has compiled an account of them which is not likely ever to be bettered.

Whereas the Australian aborigines are still in the Neolithic age, the Tasmanians never passed beyond a low Palaeolithic stage, below even the drift and cave men of Europe. They knew nothing of ground stone implements; they could not draw; their canoes were mere bundles of bark lashed together with vegetable fibre; they went usually naked, and could not sew skins together for clothing, though they occasionally used single skins for covering; they obtained fire by rubbing a stick in the groove of another stick, not by the comparatively more civilised drill-method. Their hair was black and woolly, and their colour a dull black. Their numbers were very scanty; it is doubtful whether there were ever more than 200 in the island at any time during the British occupation. These were divided into, maybe, sixteen 'tribes,' which varied in number from 30 to 200, and spoke separate dialects of a single language; the tribes and dialects can be again grouped into four chief divisions—southern (below Hobart), western (along the coast from South-west Cape to Emu Bay), central (between Hobart and a line drawn from the Great Lake to St Patrick's Head), and north-eastern. Of these the central tribes were the biggest and most important, and came most into

contact (and conflict) with the European settlers. Of their social and religious systems very little is known, and what is known is of doubtful value, since the facts were observed for the most part after the introduction of a 'tame mob' of black-fellows from the mainland, and may have been the result of their teaching. But the religion was apparently a form of fetish-worship, and there are traces of a totem system and of several tabus. Such government as there was seems to have been patriarchal.

It is usually stated that the last of the Tasmanian aboriginals, a woman named Trucanini, died in 1873. She was certainly the last of the free aboriginals who had inhabited the main island; but there is some probability that the last aboriginal of pure blood was Fanny Cochrane, born on Flinders Island of pure-blooded native parents after the deportations. Her native name, if she had one, is not known; her European name was given her by the catechist at the settlement where she lived as a girl.

Industries.—Up till a few years ago Tasmanian industries were practically all primary, and the prosperity of the island depended on its sheep, its mines, and its apple-orchards. The restricted area of its pasturages has always limited the expansion of its flocks, which for many years have numbered about 2 per cent. of the Commonwealth total. But the value of their wool amounts to nearly 4 per cent. of the Commonwealth total, since the island is Australia's chief nursery of stud merinos and of Shropshires. An important mineral district lies east of Launceston, tin and some gold being found in the north-east (Ringarooma district), and gold and coal in the upper valley of the South Esk. The chief mineral wealth lies, however, in the north-west, where the tin of Mount Bischoff, the silver-lead of Zeehan, and the gold and copper of Mount Lyell have yielded huge dividends to shareholders all over the world. No other district of Australia—except perhaps the tableland behind Cairns in northern Queensland—is so rich in a diversity of minerals: the value of the yield of gold, silver, lead, zinc, tin, copper, and osmiridium since 1875 is estimated at nearly 50 millions sterling. Iron, too, is found in the valley of the upper Blythe and at Mount Heemskirk, and magnetite in the basin of the Pieman River.

Roughly speaking, northern Tasmania is the home of sheep; eastern and western of the mining industry; the southern valleys, especially those of the Derwent and Huon, are packed with apple-orchards. The export of apples began in 1884, but was insignificant until the nineties; in 1914 over 2,000,000 cases were exported—half to the mainland states, half overseas. The progress since that year may be judged from the following table:

	To Mainland States.	Beyond Australia.
1914	1,096,397	951,722
1916	945,749	814,500
1918	825,058	None (no shipping was available).
1920	1,271,697	457,833
1922	1,399,530	1,354,553

These figures indicate that the Australian market is taking regularly all it needs, and expansion cannot be looked for there except in consequence of a great increase in population; the overseas market, which still affords opportunities for expansion, is unfortunately dependent on shipping facilities, which are conspicuously lacking.

Indeed, with a stationary wool-yield, a diminished mineral yield, and hampered apple-markets, Tasmania might have poor years in prospect but for the recent development of her secondary industries. This is due entirely to a hydro-electric

scheme, based on the great lake-reservoirs of the central plateau, which in 1926 provided 66,000 horse-power, has created within the last few years an important manufacturing district round Hobart, and is encouraging the creation of a second round Launceston. Among the new industries thus attracted to the island are electrolytic works for zinc-production, carbide manufactories, and the joint Australian establishment of three chocolate manufacturing firms, Cadbury's, Fry's, and Pascal's.

Government.—Tasmania sends six senators and five representatives to the federal parliament. The State government is of the usual Australian type (see AUSTRALIA). A council of 18 members (3 from Hobart, 2 from Launceston, 1 from each of 13 other constituencies) is chosen by electors with an educational or a small property qualification, which excludes about three-quarters of the adult population; a third of the council retires every two years. An assembly of 30 members, chosen by adult suffrage, includes 6 members elected in each of the 5 federal electorates, thus avoiding the multiplication of political divisions that confuses the organisation of the mainland states; a system of proportional representation which has been in use since 1909 seems to result regularly in an almost equal representation of parties, so that a by-election may easily create a deadlock. Members of both houses receive £150 a year; four ministers administer eight departments, and a few councillors are usually made honorary ministers. The council in Tasmania has for some reason been regarded as more of a stumbling-block to democracy than those in the mainland States, and not long ago it was altogether ignored by the lieutenant-governor (during an interregnum between two governors), Sir Herbert Nicholls deciding that council amendments to the appropriation bill were 'unconstitutional nullities,' and assenting to the bill as passed by the assembly alone. The Colonial Office, being consulted, merely said that if the lieutenant-governor was acting on the advice of his law-minister no question could arise as to the constitutionality of his action.

The State revenue averages about £13 per inhabitant, and the expenditure is slightly less; but this result is obtained only by the receipt from the Commonwealth of a special grant in addition to the 25s. per head capitation grant in which all the States share. Notable features of Tasmanian public finance are the heavy direct taxation (the highest in the Commonwealth) and the small return from public services, railways, &c.; on the other hand, the small size of the island and the compactness of its settlement make expenditure much lower in proportion to population than that of any other State.

Population, Education, &c.—At the census of 1921 the population was 213,780; on 31st March 1926 it was estimated at 212,139. As the birth-rate is well above the Commonwealth average, this decrease (which has been noticeable since 1900) must be attributed to the steady migration to the mainland of young Tasmanians looking for employment. Ninety-one per cent. of the inhabitants are Australian-born—the highest proportion in the Commonwealth—and 7 per cent. British-born. Barely 27 per cent. are collected in the capital, which is an exceptionally small proportion for Australia. Primary education is of the normal Australian type (see EDUCATION), but private elementary schools are allowed under control of a teachers' registration board. In State schools no fees have been charged since 1908. Of the secondary schools the Hutchins School at Hobart dates from Sir John Franklin's time; some of the State high schools include agricultural training in their curriculum. The University of Tasmania, established

in 1889, has 7 professors and 19 lecturers for 145 matriculated students.

See AUSTRALIA and works there cited. For the early history of the colony West's *History of Tasmania* and Backhouse's *Narrative of a Visit to the Australian Colonies* are useful; J. B. Walker's *Early Tasmania* is a careful study of early discoveries; for recent years and descriptive matter the *Handbook of Tasmania*, published in 1914, and many pamphlets issued by the Government Tourist Bureau, are worth consulting.

Tasmanian Devil. See DASYURE.

Tasman Sea. the name accepted by the Admiralty in 1891 for the sea between New Zealand and the islands to the north-west of it on one hand, and Australia and Tasmania on the other.

Tassie, JAMES (1735-99). See GEM.

Tassiusdudon, summer capital of Bluntan (q.v.).

TASSO, BERNARDO, now chiefly remembered as the father of the great Torquato, was, however, held in high esteem as a poet in his own day. Born at Venice in 1493, he belonged to an illustrious family of Bergamo, who had held the administration of the posts in Italy and other countries, and hence show in their armorial bearings a post-horn and the skin of a badger (*tasso*), of which fur the post-horses' frontlets were made. Bernardo, left an orphan, studied at Padua, where he gained the friendship of the famous Cardinal Bembo, the then oracle of literary taste, and, becoming secretary of Guido Rangone, was sent to France (1528). Here he entered the service of Renée, daughter of Louis XII. of France, wife of Ercole II. d'Este, reigning Duke of Ferrara, and mother of the Alfonso and Leonora d'Este whose influence was to be so great on the future destiny of Bernardo's famous son. A few years later we find him in the service of Sanseverino, prince of Salerno, whom he followed in many travels, joining with him the expedition of the emperor, Charles V., against the Tunisian pirates in 1535, and visiting Spain, Flanders, and France a second time.

Bernardo's literary productions had been chiefly lyrical, of the bombastical and hyperbolic type affected by the imitators of Petrarch; he had followed the movement made at this time to adapt Italian verse to Latin metrical forms. Sanseverino settled on him a pension and allowed him to retire to Sorrento, there to dedicate himself to the composition of an epic poem, the subject of which was the Amadis of Gaul and his adventures, as described in the admired Spanish romance by Ordonez de Montalvo (published about 1492). Bernardo married, probably in 1536, Porzia de' Rossi, belonging to a noble family from Pistoia in Tuscany. In 1537 a daughter, Cornelia, was born to them, and in 1544 their only son, Torquato, the future great poet. Bernardo and his wife lived in perfect peace and unity, until in 1547 their prosperity came to a sudden end. Their protector Sanseverino resisted the attempt of the imperial viceroy to establish the Inquisition in Naples, fell into disfavour with the emperor, Charles V., and, joining the French king, was outlawed and had his estates confiscated. Poor Bernardo, who had followed his patron, was included in the same sentence. His wife and children took refuge in Naples with relatives; his little son was sent to him in Rome in 1554. For some years Bernardo led a wretched life there, still more embittered by the loss of his beloved wife, who died—perhaps by poison—in sorrow and poverty in Naples, 1556. He found a refuge later at the court of Urbino, where he finished his epic, *L'Amadigi*. Bernardo went to Venice to superintend the publication of his great work (4to, 1560), but it did not bring him the fame he had hoped. The last years of Bernardo's life were passed in the service of Duke

Guglielmo Gonzaga of Mantua, who made him podestà of Ostiglia. Here, on the 4th September 1569, he ended his long and troubled career, breathing his last in the arms of his beloved son. Bernardo's chief work, *L'Amadigi*, is now entirely forgotten; it is one of the many imitations of Ariosto's romantic epic, but exaggerated and inflated in style and unreal in sentiment; the verse, however, is skilful and melodious. He began another epic, *Floridante*, finished by his son, and published in 1587. Besides his numerous lyrics (2 vols. 1749) he left a copious and interesting correspondence.

See his Letters as edited with biography by G. Campori (Bologna, 1869); the *Lettere inedite*, by l'ortoli (Mantua, 1871); and Solerti's Life of his son (1895).

TASSO, TORQUATO, son of the preceding, was born at Sorrento, near Naples, 11th March 1544. He was one of the greatest of Italian poets, though belonging to a time of decadence, to that later 16th century which saw the decline of art and literature, and religious and political liberty in the peninsula crushed under the power and bigotry of Spain. After his father was exiled Torquato lived with his mother, the exemplary Porzia de' Rossi, in Naples, and received his earliest instruction at the Jesuit school there. In 1554 he joined his father in Rome, never again seeing his unfortunate mother, who died, broken-hearted, two years later.

He showed great precocity in his studies, read Latin and Greek fluently at an early age, and composed with ease both prose and verse in Italian. He shared his exiled father's wandering life; increasing his store of learning under his careful supervision at Pesaro, Urbino, and Venice. In 1560 Tasso was sent to study law and philosophy at Padua, and while there composed and published his first work, a romantic poem in twelve cantos, *Amadigi*, which he dedicated to the Cardinal Luigi d'Este. In 1565 Tasso entered the service of this cardinal, and by him was introduced to the splendid court of his brother, Alfonso II. d'Este, reigning Duke of Ferrara. The youthful poet was appreciated and encouraged by the sisters of the duke—Lucrezia, afterwards Duchess of Urbino, and Leonora—two princesses renowned even amongst the cultured women of that day for their many brilliant gifts. Amid such congenial surroundings Tasso began his great epic poem and masterpiece, *La Gerusalemme Liberata*.

In 1571 he accompanied the Cardinal d'Este to France, and was received with favour by Charles IX. and his mother, Catharine de' Medici; and he was warmly welcomed by his brother-poets, chief amongst whom was Ronsard. On his return to Italy in the following year Tasso became definitely attached to the service of Duke Alfonso at Ferrara. This court had been the scene of the earliest revival of the profane drama in Italy towards the end of the 15th century, and it was for this celebrated stage that Tasso wrote in 1573 his beautiful pastoral play, *Aminta* (1581). The perfection of its style, moulded on classic models, and the melody of its verse won for this exquisite dramatic poem a wide popularity and many imitators. Tasso completed his great epic in 1575, and (like his father before him) submitted it before publication to the judgment of the distinguished savants and critics of the day. Their fault-finding (sometimes just, but pedantic and mixed with religious scruples) and Tasso's replies (never rebellious, and generally yielding, though always full of judgment and fine literary taste) are all recorded in his correspondence and in his *Apologia* of the poem. These conflicting considerations and discussions coming after his long poetical labours seem to have unhinged his sensitive and highly-strung mind, and in 1576 he

showed the first signs of the mental disorder which darkened all his later days. He became suspicious, melancholy, and particularly oppressed by the idea that he had offended against the church and been denounced to the Inquisition. On the 18th June 1577 Maffeo Veniero writes to the Grand-duke of Tuscany: 'Of Tasso I give you news that yesterday evening he was imprisoned for having, in the chamber of the Duchess of Urbino, drawn his knife on a serving-man, but he was arrested rather because of his disorder and to cure it than as a punishment. He is of a strange humour, believing himself to have sinned as a heretic, and also has the fear of being poisoned.' After this outbreak the succeeding years of his life are one long chronicle of mental struggles and sufferings of every kind. His first confinement lasted only a few days, and he shortly afterwards fled from Ferrara. Wandering through Italy on foot, he made his way to Naples, where he was affectionately cared for by his sister, Cornelia; but even here he found no rest. He travelled to Rome, and northwards through the principal towns until he reached Turin, on foot and so poorly accoutred and strange in appearance that the guards refused him admittance until recognised by a former friend as the great poet. He was then honourably entertained by the Duke Carlo Emanuele of Savoy. His great longing was to return to Ferrara, the scene of his early triumphs and brightest memories, and in 1579 he seized the occasion of Duke Alfonso's second marriage to present himself anew at that court. He met with a cold reception, and deeply wounded by some real or imagined slight he broke in public into furious invectives against the duke, his courtiers, and all the world. On the 15th March of the same year he was confined by order of the duke in the hospital of St Anna in Ferrara, and there he remained a prisoner for seven years. During these miserable years he produced many noble verses and philosophical dialogues, and a vigorous defence of his *Jerusalem*, the publication of which, without his leave and with many errors, had sorely grieved him. His many piteous letters of appeal to his friends and patrons, from the pope downwards, for release from prison give a most complete and heart-rending picture of his sufferings at this time. The sad figure of the good, gentle, and great poet in a madhouse, while his famous epic was delighting Italy and all Europe, is one of the most pathetic in literary history, and one which may well interest posterity, even without the romance of his supposed passion for the Princess Leonora, a passion so often alluded to by later poets (especially Goethe, Goldoni, and Byron). There seems to be no positive proof that the unhappy poet nourished any other sentiment for the princess than that of the respectful devotion, admiration, and gratitude natural towards such a patroness. Certainly no manifestation of presumptuous love for the princess was the cause of his imprisonment; all contemporary accounts of his state point to his insanity, bearing the character of religious mania. But doubtless whatever may have been the nature of his feelings to Leonora her death in 1581 must have been a new grief to him. During her fatal illness Tasso writes from prison to her chaplain: 'If my Lady Leonora is better, as it comforts me to believe, and I greatly desire, humbly kiss her hands in my name, most reverend father, letting her know that I have grieved much for her illness, the which I have not bewailed in verse, because of I know not what tacit repugnance of my mind.'

Duke Alfonso had been repeatedly petitioned to set Tasso free. The cruel contrast between his fate and the daily growing fame of his great poem

(which had been reprinted six times in a few months) had greatly excited popular interest. At length in July 1586, by the intercession of the Prince Vincenzo Gonzaga, Tasso was liberated, and at once left Ferrara, never to return. He followed his new patron to Mantua, where he remained a year, and where he wrote a tragedy, *Torrismondo*, his only and not very successful effort of that kind. Broken in health and spirits, he began again his restless wanderings from town to town, spending, however, most of these later years in Rome and Naples, where he tried in vain to recover from his mother's relatives some part of her inheritance, or from the government his father's confiscated estates. He was, however, helped and protected by many kind friends and patrons eager to show honour to so great and unfortunate a genius. He busied himself in rewriting his great epic, according to the modifications proposed by his numerous critics; he tried to observe more strictly the classic unities and historical accuracy, to remove profane episodes and to treat more of religion and theology. The result, a poor spectro of his living masterpiece, even the style and verse being inferior, was published under the name *Gerusalemme Conquistata* (Rome, 1593, in 4to), and dedicated to Tasso's latest patron, Cardinal Cinzio Aldobrandini, nephew of Pope Clement VIII. By this pope he was summoned to Rome to be crowned on the Capitol as poet-laureate, like Petrarch. The ceremony, however, never took place, for on Tasso's arrival in the papal city his already weakened health became worse, and he retired to the care of the monks of Sant' Onofrio, a quiet convent on the Janiculum, where, resigned and peaceful, he breathed his last on the 25th April 1595.

Tasso, although not the last great poet that Italy has produced, is certainly the last whose influence made itself felt throughout Europe, and his *Jerusalem* is the culminating poetical product of his age, as Dante's *Divine Comedy* and Ariosto's *Orlando* are of the two preceding centuries. In our own literature we find traces of his influence notably in Milton. His great poem is, like himself, a typical product of his time, with its blind idolatry of classic forms conflicting with newly-revived religious superstition and bigotry, but exempt from the current defects of hypocrisy, affectation, and licentiousness. As Settembrini says: 'One thing Tasso had, which few in his time possessed, a great heart, and that made of him a true and great poet, and a most unhappy man.' The sincere fervour of his piety and purity of his life are testified by his own writings and by his contemporaries. Tasso's intention was to create in his *Jerusalem* a great religious epic, his theme was to be the triumph of the warriors of the Cross in the first Crusade, and his hero was to be Godfrey of Bonillon, their commander, his material to be taken from *Historia belli sacri verissima*, by Tyrus (Basel, 1559-64). With the history of his nominal hero the poet has entwined fictitious characters and episodes, and it is these creations which give vitality to his work. The melodious verses, in which he has sung the loves of the fair Erminia and the warlike Clorinda and the beauty and wiles of the enchantress Armida, still live on the lips of the Italian people—verses whose authorship seemed to the diseased conscience of poor Tasso a sin to be repented.

Tasso's earliest biographer was his personal friend, the Neapolitan G. Manzo, the same Manzo whom Milton visited in Naples, and to whom he dedicated a Latin poem. This friend thus describes Tasso's appearance (*Vita di T. Tasso*, 1619): 'He was of tall stature and well proportioned, his complexion of perfect whiteness, the

colour of his thick hair and beard between dark and fair, his head large, his forehead square, his eyebrows and lashes black, his eyes large and blue, his nose aquiline, his lips thin and pale, and his limbs so agile that he yielded to none in fencing, riding, and jousting. More complete than any biography is the picture which is given of his outer and inner life in his copious correspondence in his dialogues and various prose-works, where he reveals himself as a most facile and eloquent prose-writer.

Among Tasso's many commentators and critics we find his great contemporary, Galileo (see the *Scritti di Critica letteraria di Galileo*, Turin, 1889). The earliest complete edition of the *Gerusalemme Liberata* is that of Bonna (Ferrara, 1581, 4to); modern reprints are those at Modena (1868) and at Florence (1889). Translations of the *Gerusalemme* have been made into many languages; in English the most famous is that of Fairfax (1600; new ed. by H. Morley, 1891); others are by Bent, Broadhead, Robertson, Smith, Wiffen, and Sir J. K. James (1868; new ed. 1884). Serassi's was long the standard biography (Rome, 1783, 4to). See also Bassano's *Studi su T. Tasso* (1880); Guasti's edition of Tasso's letters and prose writings (1854-67); D'Ovidio, *Saggi Critici* (1879); Corradi, *L'Infermità di Tasso* (1881); the *Lives* by Black (1810), Denn Milman (1850), Mrs Hasell (Foreign Classics series, 1882); and Boulting's *Tasso and his Times* (1907). The last named, it should be added, closely follows the *Life* (3 vols.) by Professor Solerti in the monumental edition of the *Opere* (1895-99); and this *Life* and edition have now been recognised by the best authorities as indispensable aids to all study of Tasso.

Taste, one of the special senses (see SENSATION). The parts of the mouth affected by rapid substances are the surface and sides of the

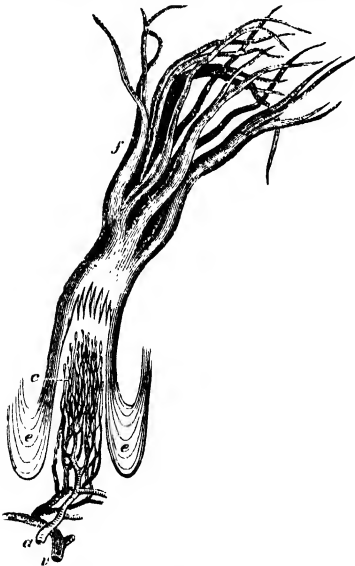

Fig. 1.

A Filiform Compound Papilla, magnified 300 diameters:

a, artery; v, vein; c, capillary loop; e, epithelium; f, hair-like processes at the apex.

tongue, the roof of the mouth, and the entrance to the pharynx. The mucous membrane is invested by stratified squamous epithelium, which, over the surface of the tongue, covers little vascular

projections termed papillæ. One can see the papillæ of the sides and upper part of the tongue with the naked eye, as little sharp or rounded projections; the latter, thickly clustered at the tip and sides, may appear, if the system is out of order, as little red points like those of a strawberry. In the cat tribe the papillæ are hard and curved backwards into the mouth, so that the animal can use the tongue as a scraper to remove the flesh from the bones of its prey. The pointed papillæ are termed 'filiform,' and one is represented in fig. 1, while a rounded papilla is seen in fig. 2. They are essentially the same in structure, differing alone in shape and size, and, were the figures drawn to some common scale, fig. 2 would have to be three or four times as big as it is. At the back of the tongue are some eight or ten papillæ of quite a different nature, called 'circumvallate.' They are arranged to form a V with its angle pointing backwards. These are hardly papillæ at all, but may be looked upon rather as tiny patches of mucous membrane trenched out from the surrounding parts. Into these trenches Ebner's glands secrete a watery albuminous fluid, keeping them perpetually moist and free from foreign particles. In the epithelium lining these trenches curious little bodies called taste-bulbs are lodged; and, as these are the parts which are probably more especially concerned in taste, they must be carefully described. Each taste-bulb looks like a flask-shaped barrel or box, the walls of which are composed (fig. 4) of flat elongated epithelial cells fitted side by side like the staves of a cask.

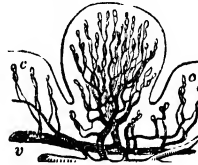

Fig. 2.—A Fungiform Papilla, with the capillary loop of its simple Papilla injected:

a, artery; v, vein. Around the base there is often a groove, which is here shown; as also the capillary loops, c, c, of two of the neighbouring simple papillæ (magnified 18 diameters).

The taste-bulbs open each by a little pore into the trench, and into the deeper part a nerve enters in the way represented in fig. 3. The cask is probably for the protection of the sensory cells which it contains, and one of which is drawn in d, fig. 4. These cells are much elongated, and end each in a tiny bristle which projects with those of their companion cells from the little pore into the trench, and is here moistened by the juice of Ebner's gland and whatever rapid substance may be present. The impressions which these sensory cells receive from the bristles, say by the action of a bitter like 'hops,' is carried by the delicate nerve which starts from the opposite end of the cell out of the taste-bulb directly to the brain. Within each taste-bulb are other cells (e, fig. 4), which separate and support the sensitive cells, and are similar to analogous structures seen in the sensory epithelium of the eye, and nose, and ear. While it is almost certain that these taste-bulbs are organs of taste, it is not equally certain that other parts are not involved. The reason for this belief is that in the front and sides of the tongue these taste-bulbs are few in number, while

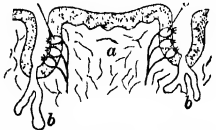

Fig. 3.—A Semi-diagrammatic View of a Circumvallate Papilla:

a, body of papilla; b, Ebner's glands opening into the bottom of the trench; c, taste-bulbs with the taste nerves leaving them.

in these regions taste sensations are pretty acute. It is therefore not improbable that the nerves which abundantly pass into the epithelium of the tongue end in other ways, but unfortunately we are at present much in the dark concerning their exact method of termination. It is to be noted

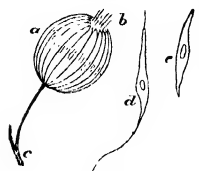

Fig. 4.

a, taste-bulb with sleeve-like epithelial jacket out of the opening of which the sensory hairs (*b*) project; *c*, the nerve passing to taste-bulb; *d*, a sensory cell taken from a taste-bulb, showing the sensory hair and its fine nerve; *e*, a supporting cell.

taste, and after about four months the corresponding buds disappear, their elements being replaced by ordinary epithelial cells.

Having sketched the mechanism concerned in the production of taste sensations, we can now turn to the discussion of the many interesting facts which may be observed when this mechanism is called into play. In the first place, it may be remarked that substances capable of dissolving in the juices of the mouth are alone tasted. Marble, wood, flint, are devoid of taste, and so is pure starch; these are all of them quite insoluble in water. By the aid of various means we can convert the last named substance into a very soluble 'dextrose,' yet this is tasteless. Another chemical product of the starch is the soluble substance termed 'dextrose,' which has a sweet taste and is commonly termed 'grape-sugar.' These examples will serve to illustrate the general fact that substances to be tasted must be in solution, though not all soluble substances are capable of giving rise to this sensation. It is a matter of general experience that, if a substance like sugar be simply placed in the mouth and allowed to dissolve, its taste is only faintly evident. If, however, the juices of the mouth, sweetened by the sugar, be rubbed into the mucous membrane by moving the tongue against the palate, the sensation is greatly intensified. One invariably 'smacks the lips' in trying to appreciate the qualities of a taste, and obtains in this way its maximum effect.

A fact that is hardly known by the laity is that most of the so-called tastes are really 'smells.' Sugar, salt, quinine, and some acids are devoid of smell; we could not distinguish them except by the tongue itself, and we have in these the prime taste sensations of sweet, salt, bitter, and acid. Meat, wines, and fruit are smelt, not tasted, and a bad cold dulls our appreciation of these articles of diet. To the prime taste sensations already mentioned may be added perhaps alkaline, astringent, and metallic tastes, but when all is told this organ yields so rough results when compared with smell, sight, or hearing, whereby hundreds and thousands of shades of quality are readily perceived in the odour of flowers, the lights from coloured objects, and the sounds from an orchestra. The various taste sensations are not equally produced on stimulating the whole of the gustatory area, and indeed each taste seems to have some special locality at which it is most acutely felt. If we take a piece

of quassia or a hop-leaf and chew it, we shall at first be unconscious of taste, and it is only when the juice of the mouth laden with these bitter principles passes to the back of the mouth that the taste is felt at all. This is why we drink beer in the draught, and do not sip it like wine. The sweet or acid wine is tasted best by the front part of the tongue, while the bitter beer is only appreciated as it is going down the throat. As in the other senses, anything that stimulates the gustatory nerve gives rise to a sensation; and although sapid particles effect this best of all, electrical or even mechanical stimuli have some effect. If we place a piece of zinc and copper on the tongue, and join them so as to give rise to a feeble current, or still better, if a slight interrupted electrical current be passed through the mucous membrane of the tongue, metallic saline tastes are produced. These are possibly due to electrolytic changes and not to direct stimulation, though this is less likely to be the case with the induced currents, equally powerful in the production of sensation. It is often stated that a sharp tap on the tongue produces a sweet or saline taste; this is, however, an experiment which often fails. If we rub the back and side of the tongue with the finger tip we shall hardly fail to notice a bitter taste, and it is probable that we shall question the cleanliness of the finger used. A scrupulously cleaned glass rod gives rise, however, in equal measure to the same sensation, and we are forced to conclude that the mechanical stimulus of the rod calls forth that taste which has its seat in the back of the mouth and tongue.

In daily life we make a distinction between the sapid substances based on the affective impression they make upon us rather than on the quality of their tastes, and thus we discriminate between agreeable, indifferent, insipid and disagreeable tastes. Agreeable and disagreeable substances excite different expressional movements of the facial muscles, the former tend to be kept longer in the mouth, the latter to be spat out or swallowed quickly; indifferent and insipid substances produce no facial movements, or at most arouse an expression of indifference or slight disgust. These reactions are involuntary, and may be considered as instinctive reflexes. In addition to the four primitive tastes—sweet, bitter, acid, and salt—we commonly speak of many other tastes such as alkaline, metallic, astringent, acrid, sharp, aromatic, fatty, stinky, dry, &c., but these on analysis are compound, and consist of several elementary constituents in which the sense of taste is mingled with olfactory sensations, and with tactile, thermal, and pain sensations of the mucous membrane of the mouth. In testing the sense of taste the tongue should be protruded and drops of the solution to be tested applied with a camel's hair brush to the different parts, the subject of the experiment signifying his sensations by signs, for if he withdraws the tongue to speak, the material gets widely spread. The more concentrated the solution, the larger the surface acted on, and the more intense the taste. Some tastes are perceived more rapidly than others; saline tastes the most rapidly of all. The solution is best to be about body temperature, as very high or very low temperatures deaden the sense. If we make of substances belonging to each of the four elementary groups solutions that will arouse equal sensations we cannot distinguish between the sensations aroused by hydrochloric, nitric, sulphuric, acetic, and oxalic acids. The same applies to bitter substances such as strychnine, quinine, morphine, picric acid, &c., and also to sweet solutions like sugar, glucose and lactose. Many facts point to the conclusion that the varieties of gustatory, like those of cutaneous sensation, are

due to the stimulation of different end-organs, while investigation of the papillæ shows that they present marked functional differences. Cocaine abolishes especially the bitter taste, and gymnemic acid (prepared from the leaves of the plant *Gymnema sylvestre*) abolishes the sweet taste, leaving the salt and acid tastes almost untouched. The four primary tastes are discontinuous qualities, which cannot be arranged in series like musical tones of different pitch. But however they may differ among themselves, they all have something in common which distinguishes them collectively from every other category of sensation, and which strongly suggests that all tastes are to be regarded as different qualities of one and the same modality of sensation, i.e. of one sense. This view is supported by the phenomena of *contrast* and of *compensation*. The former is illustrated by the fact that after excitation of the tongue with dilute sulphuric or hydrochloric acid distilled water is perceived as a sweet fluid, and the latter by the use of sugar to compensate for the bitter taste of coffee and the acid taste of lemonade, although it does not produce a new taste; both tastes persist, and there is a mixed or more agreeable sensation experienced. A still better example is seen on mixing weak solutions of sugar and salt in a certain ratio, the result being an insipid alkaline taste recalling neither sugar nor salt. The effect is lost in more concentrated solutions. It is by these effects of compensation of different tastes, as well as by the varied association of gustatory with tactile, thermal, and olfactory sensations that the flavour of nauseous medicines is corrected, and the different ingredients of food materials are so combined as to convert the four primary tastes into innumerable complex flavours.

We are almost entirely ignorant of the chemical or physical properties which enable certain substances to be tasted and others not. Taste and smell are two specific and closely allied senses which may be termed *chemical senses*, because the adequate stimuli for both consist in special chemical substances, which are soluble in water. They often function together. They are specially co-ordinated for the control and selection of foods and beverages, their position at the entrance to the alimentary tract enabling them to act together for this purpose.

Tatars (incorrectly TARTARS), originally certain Tungusic tribes in Chinese Tartary, where they are recorded in the annals of various dynasties under the names first of *Tatan* and later of *Tata*. Before Genghis Khan's time we read of the White and the Wild—including the Water and the Black varieties; but Genghis Khan's particular tribal brand fell under the Black *Tata* appellation, until he united the others and himself chose the special name of *Mengku* (Mongol), which had already existed locally for centuries (see *MONGOLS*). The ultimate or remote origin of the word *Tatan* appears to be eponymous, having reference to a conquering Tungusic chief of the 3d century A.D. named *Tatan*. The word *Tatar* was extended to those hordes which were the terror of the European middle ages, the word *Mongol* never having been accepted in Europe. The name, originally Turkish and Persian *Tatar* when it approached western Europe, was doubtless changed to *Tartar*, either consciously or unconsciously, because they were supposed to be like fiends from hell (Gr. *tartaros*, 'hell'): this fanciful appellation has its origin in a letter to his mother by Louis IX. of France previous to marching against the other infidels in the Holy Land. The term is used loosely throughout Europe to this day for tribes of mixed origin in Tartary, Siberia, and the Russian steppes, including Kazan Tatars, Crim Tatars, Kipchaks, Kalmycks, &c., and has

no definite ethnological meaning. In the classification of languages 'Tartarie' is used of the Turkish group. See *TURKS, MONGOLS, and TURANIANS*; and Parker, *A Thousand Years of the Tartars* (1925).

TARTARY is the name under which, in the middle ages, was comprised the whole central belt of central Asia and eastern Europe, from the Sea of Japan to the Dnieper, including Manchuria, Mongolia, Chinese Turkestan, Independent Turkestan, the Kalmyck and Kirghiz steppes, and the old khanates of Kazan, Astrakhan, and the Crimea, and even the Cossack countries; and hence arose a fanciful distinction of Tartary into European and Asiatic. But latterly the name Tartary has often had a much more limited signification, including only Chinese Turkestan and Western Turkestan.

Tate, Sir HENRY, Bart. (1819-1899), English sugar magnate, art patron, and public benefactor, was born at Chorley, Lancashire, and entered the sugar trade in Liverpool. After the adoption of a new invention in 1872, he developed a huge business in cube sugar, migrating to London in 1880. Of the large fortune which he accumulated he gave liberally to various institutions, including the university of Liverpool, but he is especially remembered for his gift to the nation of the National Gallery of British Art (the 'Tate Gallery') at Millbank, London. The gallery, containing amongst others over sixty pictures from Sir Henry's valuable private collection, was opened in 1897 and has been extended several times since that date.

Tate, NAHUM, was son of Faithful Tate, D.D., and was born in Dublin in 1652. He had his education at Trinity College, Dublin, succeeded Shadwell as poet-laureate in 1692, is described by Oldys as 'a free, good-natured, juddling companion,' and died August 12, 1715, in the precincts of the Mint at Southwark, then a sanctuary for debtors. His writings include ten dramatic pieces, one of them an adaptation of *King Lear*: *Pompey*, or *a Poem on Tea*; various birthday odes, and an elegy on the death of Queen Mary; *Miscellaneous Sacra*; the *Innocent Epistle*, or *Art of Angling*. But his name survives from the Second Part of *Absalom and Achitophel* (revised by Dryden), and the metrical version of the Psalms, executed in conjunction with Nicholas Brady (q.v.). Completed by 1696, it slowly made its way into general use in the Church of England, supplanting Sternhold (q.v.) and Hopkins. The work as a whole was poor, but portions are not without poetic quality. The *Supplement to the New Version* (1703) was most probably the work of Tate alone; one thing in it, 'While shepherds watched,' has travelled over the Christian world.

Tatian, a Christian apologist born early in the 2d century (110, Zahn), was an Assyrian by birth, studied Greek philosophy, and wandered as a sophist round the Roman world, but about 160 at Rome was won to Christianity by the simple charm of the Old Testament Scriptures and the example of the purity and courage of the Christians. He became a disciple of Justin, in whose lifetime he wrote his *Oratio ad Græcos*, a glowing and uncompromising exposure of the faults of heathenism as compared with the new 'barbarian philosophy.' After Justin's death (166) Tatian fell into evil repute for heresies, and he retired to Mesopotamia, probably Edessa, writing with characteristic fearlessness and vigour treatise after treatise. He was certainly infected with Gnostic notions of the universe, the supreme God, the demiurge, and the world of æons; but the notions of his which gave most offence were his excessive asceticism, his rejection of marriage and animal food, and adoption of the practices of

the Encratites. His name became a synonym for all manner of dangerous and unsettling tendencies, and his doctrines were assailed in turn by Irenaeus, Tertullian, Hippolytus, Clement of Alexandria, and Origen. Neither the place nor date of his death is known, but it took place perhaps at Edessa, and probably about 180. Of his writings a great part has perished, yet one maintained a place of importance in the Syrian Church for two hundred years, and supplies one of the most interesting chapters in the history of sacred literature. This was the *Diatessaron*, a gospel freely constructed out of the four gospels known to us, not a harmony in the modern sense, but a kind of patchwork gospel, its principle *anaglogation* not *comparison* in Lightfoot's phrase. This may have been written in Greek and in Syriac. There is no mention of the *Diatessaron* in any Latin writer before the middle of the 6th century, when Victor of Capua attributes an anonymous gospel harmony he had found to Tatian. Of Greek writers the first to mention it is Eusebius. Epiphanius says, 'the *Diatessaron* gospel is said to have been composed by him [Tatian]. It is called by some the gospel according to the Hebrews.' But on Syrian soil in Theodoret, bishop of Cyrrhus, near the Euphrates, we first find (453) an explicit account of the book: 'He [Tatian] composed the gospel which is called *Diatessaron*, cutting out the genealogies and such other passages as show the Lord to have been born of the seed of David after the flesh. This work was in use not only among persons belonging to his sect, but also among those who follow the apostolic doctrine, as they did not perceive the mischief of the composition, but used the book in all simplicity on account of its brevity. And I myself found more than two hundred such copies held in respect in the churches in our parts. All these I collected and put away, and I replaced them by the gospels of the four evangelists.' Thus we see that in the 5th century this work was used in the Syrian churches as the form in which the gospel was read, and further back still we find evidence of its use in the 3d-century *Doctrine of Addai*, and in the *Homilies of Aphraates* (fl. 340) and the famous Ephraem Syrus. Bar-Salibi, a Syrian bishop (12th cent.), distinctly states that Ephraem wrote an exposition of Tatian's *Diatessaron*. This survives in an Armenian version (perhaps 5th cent.), with which the Latin harmony of Victor of Capua, as found in the *Codex Fuldensis*, is substantially identical. In 1881 Zahn published his masterly monograph on Tatian's *Diatessaron*, containing a reconstruction of the text from the Latin, based on Ephraem's Commentary, on the quotations in Aphraates, and occasional parallels with the *Codex Fuldensis*.

Harnack thus sums up the conclusions that may be drawn from what may be considered as proved: (1) In Tatian's time there was still no recognised N.T. Canon, and the texts of the gospels were not regarded as inspired; (2) about 160 our four gospels were already in existence and authoritative, and the fourth on an equality with the three synoptics; (3) the text of the gospels in 160 was substantially the same as it is now, save that intentional changes and interpolations were made later, as the passage about the church being built upon Peter the rock.

See J. H. Hill, *The Earliest Life of Christ: The Diatessaron of Tatian* (translation and notes, 1893); Zahn, *Forschungen zur Geschichte des neutestamentlichen Kanons* (1881-91), and *Geschichte des neuesten Kanons* (1891); *Texte und Untersuchungen zur Geschichte der altchristlichen Literatur*, by O. von Gebhardt and A. Harnack (Bd. iv. 1888); E. Schwartz's *Texte und Untersuchungen* (1888); the work by Hemphill (Dublin, 1888); the Study by Rendel Harris (1890); relevant

articles in *Ency. Brit.*, Herzog-Haack's *Real-Encyclopädie*, and *The Catholic Encyclopedia*. For translations, see the *Ante-Nicene Christian Library*. Dr Rendel Harris in *Perfection according to the Saviour* (1924) claims to have traced one of the lost treatises.

Tatius, ACHILLES, one of the Greek romancers, seems to have written in the 3rd century A.D., or early in the 4th. He belonged to Alexandria, and was much influenced by the rhetorical school of poetry, which owned Nonnus as its master. Suidas tells us that he became not merely a Christian, but a bishop, after writing his romance of *Leucippe and Cleitophon*, but the accuracy of this may well be doubted. It is possible also that he was the author of treatises on etymology and astronomy. His romance comes next to the *Theagenes and Chariclea* of Heliodorus in time, and perhaps in merit. The author describes himself as gazing at the picture of Europa in the temple of Venus in Sidon, when he is accosted by Cleitophon, who straightway tells him his whole adventures in eight books. The plot is sadly lacking in probability, and grows positively wearisome towards its long drawn out conclusion. Its artistic development is marred by the introduction of much irrelevant discourse on painting, sculpture, and natural history, and moreover much of this is mere wordy rhetoric. The delineation of character is feeble to a degree—the hero a mere shadow of a man, uninteresting in everything save devotion to his mistress, who is much better drawn in every respect. Still the dawn of love in Cleitophon's heart is well described, and the doubts and fears characteristic of the passion are well realised, and reveal a striking knowledge of the human heart. Many of the situations are wise than indelicate, but the morality of the purpose, so characteristic of the Greek romances even in their indecencies, is evident throughout. The Greek is elegant, yet unaffected.

Editions are in the *Erotici Scriptores Graeci* by Hirschig, Le Bas, and Boissonade (Paris, 1856), and Hercher (Leip. 1858-59); also separately, by F. Jacobs (Leip. 1821), and by Gaselee (with translation 1917). There is a French translation in Ch. Zévort's *Romans Grecs* (Paris, 1856); an English, by the Rev. R. Smith (1855). See A. Chassigny, *Histoire du Roman dans l'Antiquité Grec. et Lat.* (Paris, 1862); E. Rohde, *Der griech. Roman und seine Vorläufer* (Leip. 1876); and Dunlop's *History of Prose Fiction* (vol. i.), edited by Henry Wilson (1888).

Tatra. See CARPATHIANS.

Tattersall's, a celebrated mart in London for the sale of racing and other high-class horses, and one of the principal haunts of racing men, so called from Richard Tattersall (1724-95), a native of Hurstwood in Lancashire, who came early to London, entered the service of the second Duke of Kingston, and ultimately became an auctioneer. In 1766 he took a ninety-nine years' lease from Lord Grosvenor of premises in Hyde Park Corner, and after its expiry Tattersall's was removed to Knightsbridge Green (1867). In 1779 Richard Tattersall bought the famous horse Highflyer of Lord Bolingbroke for £2500, and named his house at New Barns, near Ely, Highflyer Hall. Here he was often visited by the Prince of Wales from Newmarket. The prince was also a joint-owner with 'Old Tatt' in the *Morning Post*, and lost thereby £10,000, which was paid to Tattersall's heirs in 1810. See *Memories of Hurstwood* (Burnley, 1889), by Tattersall Wilkinson and J. F. Tattersall.

Tatu, a term imported into European languages in the 18th century, derived from Tahiti *tatau*, from a root *ta*, 'to strike.' In its strictest sense the word refers to skin marks produced by puncture with a needle or pointed instrument, followed by the introduction of a pigment which

gives visibility and permanence to the designs. This type is in the main a feature of bodily decoration among peoples of medium pigmentation, such as the Polynesians; but it is also recorded among full-blooded negroes, despite the inconspicuous result; for the Kru of Liberia have a blue mark down the forehead, and some of the Bauchi tribes of Nigeria also rub in a blue pigment; but it must be noted that it is not possible to class either case with typical tattooing, because the skin is opened by cutting. It must, however, be noted that moko, the type of tatu in use in New Zealand, was produced by cutting grooves in the skin with a kind

Tattooed Maori Chief.

of chisel; so deep did it penetrate that a smoker's cheek might be perforated so that the smoke issued through the orifice. In a secondary sense the term tatu has been used of other modes of decorating the body, such as the production of raised scars (keloids), widely spread in Africa, body painting either with coloured pigments, as among the Red Indians, or with vegetable juices, as in Africa, both of course more or less

temporary; finally may be mentioned, though it is not alluded to as tatu, the custom of using white pigment or chalk, the former as a world-wide element in initiation rites, the latter, especially in Africa, for religious or magical purposes.

The body marks produced in these various ways served a great variety of purposes. Yellow or white paint may be a sign of mourning—i.e. of separation from the profane world, of which the initiation rites are another example (see TABU). The marks may also be almost purely decorative, or, at least, become so, and serve the object of attracting the other sex; it is certain that this is the case with the tatu of Polynesia, but it must be remembered that the same is true, to a large extent, of the effect produced by any kind of fashionable deformation. It may be noted in passing that, at least in the eyes of Europeans, another effect of body tatu is to remove the impression of nakedness, even when clothing is wholly absent; but this can hardly be a primary purpose, if only because, especially among the darker skinned peoples and those accustomed to nudity, habituation makes even the European observer unconscious of the lack of clothing. Another purpose served is to cause fear in an enemy or to indicate deeds of valour already performed. The more permanent forms are also used to indicate the tribe or clan of the wearer, a point of some importance in Africa, perhaps, in the days of slavery. They may also indicate certain offices or grades or a certain status; thus the son of an Ibo chief at Aguku received diagonal scars across the face fourteen days after birth; in America the keepers of the tribal pipes had a special tatu design, to which was added a skull when he cut off the head of an enemy; the Eskimo whaler keeps a tally of his kills by tatu marks on cheek, chest, or arms. Wholly different again is the use of one or other method as a remedy for bodily ailments or as a love charm. Again, as an identity mark tatu of some kind may be held to be a necessity in the future life, without which the lot of a man will be evil. In China one kind of punishment is to tatu the offender, and in Samoa

the criminal had to submit to the tattooing of his nose.

There is a good deal of variation according to age, sex, &c., both as regards the kind of design and the part of the body selected for it. The Maori woman was tattooed on the chin only; but the moko of the male covered the whole face as well as other parts of the body; in Central Polynesia, on the other hand, the face was left untouched. It is worthy of note that tatu was frequently used on parts of the body concealed by clothing. From this and many other facts it is clear that it was not originally decorative but had ritual significance. It was, for example, obligatory on the Marquesan warrior and chief to receive tatu marks; only the tattooed might partake of the cannibal feasts in former times. Among the Kayan of Borneo the operation may not be performed in seedtime nor if a corpse is in the house; while it is in progress the males of the family wear a special garment and remain indoors; the operation must be performed in a special hut; the operator observes many ritual prohibitions; he has a tutelary spirit, and he may not begin his functions till his children are grown up. The tattooed Kayan woman may not eat monitor lizard; nor may her husband before the birth of the first child. Similar rules are found in other areas; in New Ireland the subject is isolated before the operation is begun; before his moko is completed the Maori might not use his hands to put food into his mouth, for his head had acquired a sacred character (see TABU).

Tatu proper is found in many parts of the world, and at present there is no evidence to prove that the practice spread from a single centre; it is found in North and South America, Polynesia, Melanesia and Micronesia, Indonesia, India, parts of Africa, east Asia, &c.; it is well known in modern Europe, but probably only as a borrowed practice, though Herodotus records that Thracian women were tattooed as a mark of nobility; it is probable that body decoration of some sort was known in Gaul and Britain. Tatu proper seems to have been practised by the Nubians in 2000 B.C. and possibly in Egypt; it was in use in south China in 1100 B.C.

W. Joest, *Tatuieren*, is mainly concerned with the technique of the operation; von den Steinen, *Die Kunst der Marquesaner*, deals also with tatu in other areas; W. G. Robley, *Moko*, contains a good deal of information on Maori tatu; and see W. D. Hamby, *History of Tattooing* (1925).

Tauchnitz, KARL CHRISTOPH TRAUGOTT, a famous German printer and bookseller, was born at Grosspandau, near Leipzig, October 29, 1761. Bred a printer, he set up in 1798 a small printing business of his own in Leipzig, with which he shortly after conjoined publishing and typefoundry, and all his enterprise only added to his prosperity. In 1809 he began to issue editions of the Greek and Latin classics, the elegance and cheapness of which carried them over the learned world. He was the first to introduce (1816) stereotyping into Germany, and he also applied it to music. On his death, 14th January 1836, the business was continued by his son, KARL CHRISTIAN PHIL. TAUCHNITZ (1798-1884).—A nephew of the elder Tauchnitz, BARON CHRISTIAN BERNHARD VON TAUCHNITZ, born at Schleinitz, 25th August 1816, also founded in 1837 a printing and publishing house in Leipzig. In 1841 he began his well-known collection of 'British Authors,' of which 2600 volumes appeared within the first fifty years. The enterprising publisher was ennobled in 1860, and made a life-peer in 1877, and died Aug. 13, 1895. His son BARON BERNHARD VON TAUCHNITZ succeeded him, and died in 1921.

Tauler, JOHANN, German mystic, was the son of a wealthy citizen of Strasburg, where he was

born about 1300. His education was entrusted to the Dominicans in Strasburg and Cologne. When Tauler was twenty-four years of age the clergy of his native city, where he then lived, were prohibited from performing the religious services in consequence of a papal interdict having been launched against Strasburg, because it took a different side from the pope in a disputed imperial election. Tauler, however, and his colleagues continued to officiate. But the heads of the order forbidding them to do so, the magistrates banished the Dominicans from the city. For some seven years or so Tauler found refuge in Basel, where coming in contact with the Friends of God, a sort of free association for deepening religious life, his views underwent a great change. Some ascribe this 'conversion' to Nicholas of Basel; others discredit the fact altogether; whilst others again admit it, but dispute the identity of the agent. At all events, from this time forward Tauler became the centre and source of the quickened religious life in the valley of the middle Rhine, his reputation as an eloquent and earnest preacher spreading far and wide. His banishment over, he returned to Strasburg, and is believed to have stayed behind there during the Black Death, to minister to the sick and sustain the courage of the living. He died in 1361. Prior to his conversion Tauler seems to have been a disciple of Master Eckhart (q.v.), at whose feet he probably sat when a young student, and thus he belongs to the Mystics (see MYSTICISM). The change that took place in him at Basel turned his thoughts from speculative thinking to pious exhortation and practical doing; and it is this note of sincere practical piety that especially distinguishes his *Sermons*, which are reckoned amongst the finest in the German language.

See K. Schmidt, *Johann Tauler* (1841); two works by Denifle (1877-79); one by Siedel (1911); Preger's *Geschichte der Deutschen Mystik* (vol. II, 1893); Miss Winkworth, *Tauler's Life and Sermons* (London, 1897).

Taunton, a pleasant, well-built town of Somersetshire, in the fair and fertile valley of the Tone ('Taunton Deane'), 45 miles SW. of Bristol. Here about 710 B.C. the West Saxon king, built a fortress, which, passing with the manor to the bishops of Winchester, was rebuilt by Bishop William in the first quarter of the 12th century. Added to in the 13th and 15th centuries, this castle received Perkin Warbeck (1497), and was held by Blake (q.v.) during his famous defence of the town (1644-45). In its great hall, fitted up now as a museum, Judge Jeffreys opened the 'Bloody Assize,' hanging 134 and transporting 400 of the inhabitants of Taunton and the neighbourhood who had accorded Monmouth an enthusiastic welcome (1685); and here too Sydney Smith made his 'Mrs Partington' speech (1831). The church of St Mary Magdalene has a noble Perpendicular tower 153 feet high (c. 1500; rebuilt 1858-62); and other buildings are the Elizabethan shire-hall (1858), the municipal buildings (formerly the grammar-school founded by Bishop Fox in 1522), King's College school (1880), Independent college (1847-70), Wesleyan Institution (1843), Hindu schools (1874), Bishop Fox's girls' school, hospital (1809-73), barracks, &c. Formerly one of the great 'clothier towns' of Somerset, Taunton now has shirt, collar, glove, and silk manufactures, with a large agricultural trade. It was thrice chartered (1627, 1677, 1877) as a municipal borough, and had two members till 1885, one till 1918. Pop. (1921) 23,223. Extension of boundaries added about 1000 in 1924.

Taunton, capital of Bristol county, Massachusetts, at the head of navigation on Taunton

River, 34 miles by rail S. of Boston. It contains a fine park, Bristol Academy (1792), a court-house, city hall, a state lunatic asylum, and numerous foundries and cotton-mills, locomotive and copper works, shipyards, and manufactories of bricks, nails, jewellery, &c. Taunton was settled from Taunton in England in 1637. Its first minister was William Hooke, who afterwards married Cromwell's cousin, and became his chaplain. Pop. (1920) 37,137.

Tannus Mountains. See HESSE-NASSAU.

Taupo, LAKE, a beautiful lake in the middle of North Island, is the largest (238 sq. m.) in New Zealand. Its greatest depth is 534 ft. The volcanic cliffs of its western shore reach 1000 feet sheer at Karanghape Bluffs. There are hot springs in the lake; and towards the south-east is the island of Mountaiko, apparently an extinct volcano. The Waikato enters the lake at its southern corner and leaves it at its north eastern.

Taurida, a former government of South Russia, bounded on the E., S., and SW. by the Sea of Azov and the Black Sea, and including the peninsula of the Crimea (q.v.). It is now divided between the republics of Ukraine and Crimea.

Taurus, MOUNT. See ASIA MINOR.

Tautog (*Tautoga onitis* or *americana*), a fish of the family to which the Wrasse (q.v.) belongs, found in the North American seas, and in great request for the table. It attains the weight of 12 or 14 lb. Its colour is black on the back and sides; the belly is whitish; each jaw has a double row of strong conical teeth; the face is covered with a scaleless integument. It is also called Black-fish and Oyster fish.

Tautpheus, BARONESS (1807-93), the daughter of James Montgomery of Seaview, Co. Donegal, married in 1838 an official at the Bavarian court. She wrote a series of novels in English, mainly pictures of South German life, manners, and history, including *The Intells* (1850), *Cyrilla* (1853), *Quits* (1857), and *At Odds* (1863). Florence Montgomery (q.v.) was her niece.

Tavastehus, or HAMEENLINNA, a town of Finland, capital of the province of Tavastehus (or Häme). The first Finnish railway was constructed in 1862 between Tavastehus and Helsingfors (66 miles). Pop. of town, 7000; of province, 370,000.

Tavern. See INN, LICENSING LAWS.

Taverner, JOHN, 16th century English composer, was organist at Boston, and then at Christ Church, Oxford, shortly after its foundation, and died probably before the accession of Edward VI. His compositions—motets and masses for Roman Catholic ritual—are notable.

Tavernier, JEAN BAPTISTE, BARON D'AUBONNE, a celebrated French traveller, was the son of an Antwerp Protestant engraver who had settled in Paris, and was born there in 1665. The conversation of the savants who frequented his father's shop made him a traveller at fifteen, and by the age of twenty-two he had seen France, England, the Low Countries, Germany, Switzerland, Poland, Hungary, and Italy. His *first journey* to the East lasted from about the beginning of 1691 to the summer of 1693, by Constantinople to Persia, thence by Aleppo and Malta to Italy. The *second journey* (1693-43) was from Marseilles to Alexandria, across Syria to Ispahan, thence to Dacca, Agra, Surat, Goa, and Golconda; the *third* (1643-49), through Ispahan, much of Hindustan, Batavia, and Bantam, whence to Holland by the Cape and St Helena; and in the *fourth* (1651-55), *fifth* (1657-62), and *sixth* (1663-68) many districts of Persia and India were visited, the outward route being generally by way of Syria and the

Arabian Desert, and the return one by Asia Minor. Tavernier invariably travelled as a dealer in precious stones and other valuable articles of small bulk, and the great profits he realised strongly impressed upon him the advantages of regular commerce between Europe and the East. He was well received by most of the eastern potentates - the Shah Abbas II. in 1657 gave him a robe of honour and made him his jeweller in ordinary, and the Great Mogul Aurangzebe kept him to see his annual festival in 1665. Louis XIV. gave him 'letters of nobility' in 1669, and next year he bought the barony of Aubonne near Geneva. In 1684 he started for Berlin to advise the Elector of Brandenburg in his projects for eastern trade. Next year he sold his estate, but it is quite unlikely that he was thrown into the Bastille after the revocation of the Edict of Nantes. He sent his nephew to India with a valuable cargo, but is supposed to have been defrauded by him. In 1687 we find the veteran traveller obtaining a passport in Switzerland, next year he appears to have been at Copenhagen, and in February 1689 he arrived in Russia, where he died at Moscow before the close of the year. His famous *Seu Voyages* was published in 1676; the complementary *Recueil* in 1679. Tavernier traversed the plains of Troy, and passed the ruins of Persepolis without even a flutter of interest, and partly perhaps from this habit of mind his statements are accurate and truthful beyond the measure of travellers. But the chief value of his book lies in the fullness and accuracy with which are detailed the nature and state of oriental commerce, the chief markets and commercial routes, the precious stones found, and the various systems of coinage. Editions of the *Travels* are of 1810 (7 vols.) and 1882 (abridged).

See *Travels in India*, trans. by Dr V. Ball (2 vols. 1890), and Charles Joret, *Jean Baptiste Tavernier d'après des Documents Nouveaux* (1886).

Tavira, a seaport of Portugal, on the Sequa, 20 miles N.E. of Faro. It has sulphur-baths, sardine and tunny fisheries, and a pop. of 11,000.

Tavistock, a pleasant market-town of Devon, 11 miles N. of Plymouth and 31 (by rail 40) S.W. of Exeter, lies in a trough of the hills on the Tavy's left bank, with Dartmoor stretching away from it to the eastward. An old stannary town, till 1885 governed by a portreeve, it is the centre of what not many years ago was a great mining district; and it sent two members to parliament till 1867, then one till 1885. Two gateways, a porch, and the refectory are the chief remains of its once magnificent Benedictine abbey, founded in 961 by Ordgar, ealdorman of Devon, and father of the infamous Eilfrida. It was rebuilt between 1285 and 1458, was the seat of a very early printing-press, and had a revenue of £902 at the dissolution in 1539, when it was conferred on the first Lord Russell, remaining still with his descendant, the Duke of Bedford. The parish church (1318) is a fine structure, with a west tower (106 feet) resting on arches. Tavistock has also a guildhall (1848), corn-market (1839), covered markets (1863), statues of the seventh Duke of Bedford by Stephens (1864) and Drake by Boehm (1883), a very fine one presented by the ninth Duke, and the Kelly College (1877), founded by Admiral B. M. Kelly. Drake and William Browne were natives, Pym and William Lord Russell members; and the Right Hon. W. H. Smith was educated at the grammar-school. Pop. 4300.

Tavoy, the chief town of a district in Tenasserim, Burma, on the left bank of the Tavoy River, 30 miles from its mouth; pop. 25,000.

Tax is a term defined by Bastable as 'a compulsory contribution of the wealth of a person or body of persons for the service of the public powers.'

On this view, generally accepted nowadays, taxation, or the levying of taxes, is regarded as an affair of government (central or local). Taxation thus forms one important department of public finance, and stands in close correlation with the other, namely, expenditure. The funds normally at the disposal of the state do not all come from taxation. The state may borrow at home or abroad. Again, its revenue is often derived in part from property held and managed by public authorities: the silver mines of Laurium belonged to the Athenian republic; and in the middle ages the king of England drew a large income from his crown-lands. Or it may come in part from payments for services performed—from the fees paid by suitors in the courts, the profits of the post-office, &c. If an adequate income could be obtained from these sources, it would not be necessary to levy taxes at all; but no modern government has been able to subsist without taxation.

In England the pressing needs of the central government in the 17th century resulted in the gradual formation of a regular tax-system to replace the former one of customs duties and spasmodic levies. As the needs of government have increased the subject of taxation has necessarily been complicated with that of the desirable extent of state activity. If this is to be a minimum, taxation will be required to defray only the necessary expenses of government. But the trend of modern thought in England is towards what has been called the 'principle of maximum social advantage,' which implies that the state may tax its members and spend the proceeds as long as the gain to society as a whole is greater than would have resulted from reliance on private expenditure. Old Age Pensions, National Health Insurance, Unemployment Insurance, &c., illustrate this principle in practice.

Adam Smith's four canons of taxation, at least a *point de départ* for most subsequent studies on taxation, set forth the general principles to be applied by a taxing authority. Taxes should be certain and not arbitrary, levied with a consideration for the convenience of the contributor, and economical in their collection; it is not wise to allow the expenses of collection to eat up the tax. They ought to be just; that is to say, the sacrifice demanded from the individual citizen should be proportioned to his means. This statement, however, is ambiguous. On the one hand it is held that equality is sufficiently attained by taxing all incomes in the same proportion; on the other hand is the argument for graduated or progressive taxation, which would tax large incomes at a higher rate than small ones, the rates increasing as the amount assessed increases. Schemes of this kind are attended by considerable practical difficulties; for high taxes lead to evasion and concealment, and rich men may even be tempted to remove themselves and their capital to another country. But the progressive principle has nevertheless gained much favour with statesmen. The chief object to be kept in view is the raising of the revenue required for public purposes, but taxation may be used for other ends. For example, taxes on intoxicating liquor and other luxuries are often defended on the ground that they discourage and restrict the sale of the articles taxed. Protectionists advocate high customs duties for the purpose of excluding foreign goods from competition with native industry. There are also those who think that taxation may be used to correct social inequalities and effect a redistribution of wealth. But taxation so utilised is apt to rouse greater difficulties than it solves.

Taxes are direct or indirect. 'A direct tax is one which is demanded from the very persons who,

it is intended or desired, should pay it. Indirect taxes are those which are demanded from one person in the expectation and intention that he shall indemnify himself at the expense of another (J. S. Mill). But the distinction is merely one of convenience. Income-taxes are the most noteworthy direct taxes, and customs and excise duties the most prominent indirect ones. Historically the movement has been towards an increased use of direct taxation. Direct taxation, though apt to be inquisitorial, is preferable, because it is levied on a definite assessment, and can be adapted to the taxpayer's means. Indirect taxation is more automatically raised; labouring people especially object to be called upon to pay money, while they are hardly conscious of the large contribution they make to the revenue in the shape of tea-duty and tobacco-duty. But if customs duties are to be productive, articles of common use must be taxed and the poor are apt to be heavily burdened. The extent to which luxuries can be taxed and a reasonable revenue obtained depends on their 'elasticity,' and the possibilities of smuggling. With all taxes a point of great importance is the ultimate incidence. A duty on tea for example is levied on the importer who, by raising the price of his tea, attempts to 'shift' as much of the tax as he can on to the consumer. The argument for the *single tax* (*impôt unique*) of the Physiocrats assumed the ultimate shifting of all taxes on to the landlord, and proposed to simplify taxation by levying one direct tax on him at the outset. Henry George (q.v.) proposed a single tax on the rent of land. Besides the taxes imposed by a central government local authorities are usually permitted to levy Rates (q.v.) and duties. In some countries octroi or import duties are paid on goods brought into a town; but the octroi is even more objectionable than a duty on foreign produce, inasmuch as it tends to discourage trade between different parts of the same country.

In taxation, as in other matters, the nations of modern Europe have followed closely the precedents of the Roman empire. The revenue of the emperor was raised by means of a tributum or land-tax, customs duties varying from one-fortieth to one-eighth of the value of goods imported, excise duties on certain trades, and a tax on legacies and successions. On the fall of the empire the prevalence of feudal ideas led to a complicated system of territorial exactions: the towns were able to purchase their freedom, but the peasantry were grievously burdened. The formation of strong national governments brought little relief to the people, except when, as in England, there was a representative body strong enough to limit the demands of royal power. France under Louis XIV. may be quoted as a typical example of the evils caused by unjust taxation, unjust exemption of privileged classes, and a bad system of collection; the taxes were farmed out to private speculators, and the necessities of life were rendered outrageously dear; the salt tax especially is always named among the worst abuses of the old régime. The economists of the 18th century recalled the minds of statesmen to true principles, while practical reformers like Turgot showed them 'how to pluck the goose without making it cry.' The revolt of the English colonies in America (a revolt caused by an impolitic attempt to tax self-governing communities without their consent), the abolition of feudalism in France at the Revolution, and, still more, the close study given to questions of efficiency and justice in taxation by countless statesmen and economists since the end of the 18th century—all these factors have brought it about that the revenue laws of civilised countries have been greatly altered and improved. But there

cannot be said to exist a uniform system of taxation. Historical conditions, the extent of civilisation, the temperament of the people, all react on the character of taxation and produce as many systems as there are nations.

For particulars of the revenue of modern governments, see the *Statesman's Yearbook* and the works there referred to, and taxation is dealt with in most of the standard text-books on political economy. Among English books the best are C. R. Bastable, *Public Finance* (3d ed. 1903); G. Armitage-Smith, *The Principles and Practice of Taxation* (1906); J. A. Holson, *Taxation in the New State* (1919); B. W. Adkin, *Local Taxation* (1919); Sir J. C. Stamp, *The Fundamental Principles of Taxation* (1921), *Wealth and Taxable Capacity* (1922); H. Dalton, *Public Finance* (1923). There are American books on finance and taxation by Plehn (1886), Adams (1898), Seligman (1892, 1894, 1895, 1911), Lutz (1924). In French see the works of Do Parieu, Garnier, Leroy-Beaulieu, and Jéze, also the *Dictionnaire des Finances* (1894); and, in German, books by Schäffle, Schmoller, Stein, Wagner, Béla Foldes, &c.; in Italian by Cossa, Einaudi, Graziani, Pantaloni. See for the historical side of the subject in England: S. Dowell, *Taxes and Taxation in England* (4 vols. 1884); S. C. Buxton, *Finance and Politics* (2 vols. 1888); E. Cannan, *The History of Local Rates in England* (2nd ed. 1912); W. Kennedy, *English Taxation, 1640-1789* (1913); also works noted at POLITICAL ECONOMY, and the articles on Aids, Benevolence, Budget, Corn Laws, Customs, Excise, Free Trade, Income-tax, Land Laws, Legacy, National Debt, Poor-law, Protection, Rates, Smuggling, Tariff, Tonnage and Poundage, &c.

Taxation of Costs. See COSTS.

Taxidermy, the name given to the art of putting up natural history specimens in the dried state. It includes the skinning and stuffing of fishes, reptiles, amphibians, birds, and mammals; also the preserving, drying, and setting up of insects and other invertebrata. But it does not properly comprise the making of wet zoological preparations which are to be preserved in spirits; nor, strictly speaking, does it include the articulating of skeletons, although this is usually treated of in books on taxidermy.

For the skinning of animals a few tools, such as scalpels, scissors, and forceps, are required. Incisions must be made in certain directions. Care has to be taken not to stretch the skin in detaching it from the body, and it is necessary to avoid soiling the plumage of birds or the hair and fur of mammals with blood or grease. The skull and certain wing and leg bones are left in their place to preserve as perfectly as possible the form of these parts in case of the skin being afterwards mounted. Considerable difference of opinion has arisen as to the best treatment for preserving or, as it is sometimes called, poisoning skins. Arsenical soap is still largely used. It commonly consists of arsenious acid 1 oz., white soap 1 oz., carbonate of potash 1 drachm, distilled water 6 drachms, and camphor 2 drachms. To preserve bird skins some prefer to use some such preservative powder as the following: pure tannin 1 oz., red pepper 1 oz., camphor 1 oz., burnt alum 8 oz., all pounded together. This applies for birds, but for mammals a more satisfactory powder is formed by mixing burnt alum 1 lb. and saltpetre ½ lb. These powders should be applied to the inner surface of the skin when it is moist. A non-poisonous preservative soap of the following composition has been recommended for birds and small mammals: chalk 2½ lb., soft soap 1 lb., chloride of lime 2 oz., tincture of musk or eucalyptus oil 1 oz. But as it is difficult to prevent a little free chlorine escaping from chloride of lime, there must be some risk of corroding or rotting skins by the use of this mixture. These dry powders should be well rubbed, and the soapy mixtures carefully brushed, into the wet surface

of skins. An alcoholic solution of corrosive sublimate is a good preservative for skins, but it is very poisonous. For cleaning feathers, and especially those that are light coloured, powdered plaster of Paris is very effective. Wherever bird skins or the fur-covered skins of mammals are kept camphor or naphthaline should be present. The latter is more obnoxious to destructive moths than the former, as it has a powerful and peculiar odour. Benzine is also very useful. Butterflies, moths, and other insects require to be kept in drawers or boxes of a peculiar construction to prevent the escape of the vapour of camphor or other preservative.

Before the taxidermist can engage successfully in the processes of stuffing, modelling, and mounting an animal he requires some training in anatomy and modelling, and a knowledge of the external forms of animals, as well as some acquaintance with their habits. He cannot be a master of the art unless he has the artistic faculty in a high degree. Some of the finest specimens of the taxidermist's art are in the display of the British fauna at the Natural History Museum at South Kensington. Another most interesting display is that of Irish fauna in the Museum of Science and Art, Dublin, arranged on the 'regional' principle. How far taxidermy can be reckoned anything more than a 'tentative art' is an open question. The improvement in technique of recent times would seem to augur well, yet it has to be remembered that the taxidermist is handicapped by the ephemerality of his work in comparison with sculpture, paintings, &c.

See *Methods of the Art of Taxidermy*, by Oliver Davis (1892); *Practical Taxidermy*, by Montagu Browne (1884; 3d ed. revised by G. E. Bullen, 1922); *Field Ornithology*, by Coues (1890); and *Taxidermy*, by W. T. Hornaday (1891).

Taxila, the most populous and wealthy city of India at the time of Asoka (q.v.), was situated in the district of Rawalpindi in the Punjab.

Tay, a river of Scotland, draining nearly the whole of Perthshire, and pouring into the North Sea a greater bulk of water than any other British river, rises on Benloy, on the Argyllshire border, at an altitude of 2980 feet. Thence it winds 118 miles east-north-eastward, south-south-eastward, and eastward—for the last 25 miles as a tidal estuary, $\frac{1}{2}$ mile to $\frac{3}{4}$ mile broad, which separates Perth and Forfar shires from Fife. In the first 25 miles of its course it bears the names of Fillan and Dochart; it then traverses Loch Tay, and it afterwards passes Aberfeldy, Dunkeld, Stanley, Perth, and Dundee. Its principal affluents are the Tummel (58 miles long, and sometimes regarded as a northern head-stream), Isla, Almond, and Earn. The Tay is one of the most beautiful of Scottish rivers, and it is unrivalled for its salmon-fisheries. Vessels of 200 tons can ascend as high as Perth, but even to Dundee the navigation of the firth is much impeded by shifting sandbanks.

LOCH TAY lies 348 feet above sea-level, extends 14 $\frac{1}{2}$ miles N.E. from Killin to Kenmore, is $\frac{3}{4}$ to 1 $\frac{1}{2}$ mile broad, 508 feet deep (average, 200 feet), and covers over 10 square miles. It is a magnificent Highland lake, flanked on the north-west by Ben Lawers (4004 feet), and containing near its foot a wooded islet, with a fragment of an Augustinian priory, founded in 1122 by Alexander I., who here buried his queen, Sibylla.

See DUNDEE (for the Tay Bridge), RANNOCH, EARN, PERTHSHIRE, &c., and works there cited, with J. Geddies' finely illustrated monograph on the Tay (1892).

Taylor, JOHN JAMES, an eminent Unitarian divine, was born at Newington Butts, 15th August 1797, son of a minister in London, next at Nottingham. He studied at Manchester New College (which was located at York 1803-40), at Glasgow

University, and again at York, was ordained to Mosely Street Chapel at Manchester in 1821, and became professor of Ecclesiastical History in 1840 on the return of the college to Manchester. He spent a year (1834-35) in study at Göttingen and Bonn, removed with his college to London in 1853, becoming principal as well as professor, was joint-minister with James Martineau of Little Portland Street Chapel (1858-60), and died 28th May 1869. He wrote much for the *Prospective Review*, which passed in 1855 into the *National Review*, and made way in 1864 for the *Theological Review*, a list of as many as 102 books, discourses, and articles being appended to the collection of his *Letters*, edited by J. Hamilton Thom (2 vols. 1872).

Of the books the chief were *A Retrospect of the Religious Life of England* (1845), which Martineau styles 'the most charming of ecclesiastical histories'; *Christian Aspects of Faith and Duty* (1851); and *An Attempt to ascertain the Character of the Fourth Gospel* (1867).

Taylor, ALFRED SWAINE (1806-80), was born at Northfleet, and for forty-six years was professor of Medical Jurisprudence (on which he published a standard manual) at Guy's Hospital. He also lectured on Chemistry and wrote on poisons.

Taylor, BAYARD, an American author and traveller, was born of Quaker and German ancestry, at Kennett Square, Chester county, Pennsylvania, 11th January 1825. Having received a common school education, he was apprenticed at seventeen in a printing-office, in 1844 published *Ximena*, a volume of poems, and started on a pedestrian tour of Europe, and in 1846 published *Views Afoot, or Europe seen with Knapsack and Staff*. After his return he edited a country newspaper, then went to New York, and obtained a post on the *Tribune*. As its correspondent he made extensive travels in California and Mexico, recorded in *El Dorado* (1850), and up the Nile, and in Asia Minor, Syria, across Asia to India, China, and Japan—recorded in his *Journey to Central Africa and Land of the Saracens* (1854), and *Visit to India, China, and Japan* (1855). Later explorations are recorded in *Northern Travel* (1858), and *Travels in Greece and Russia* (1859). In 1862-63 he was secretary of legation at St Petersburg; in 1874 he visited Iceland. In May 1878 he became ambassador at Berlin, where he died 19th December of the same year. His principal reputation, however, was as a poet. His works include *Rhymes of Travel* (1848); *Book of Romances, Lyrics, and Songs* (1851); *Poems of the Orient* (1854); *Poems of Home and Travel* (1855); *The Poet's Journal* (1862); *Poems* (1865); *The Masque of the Gods* (1872); *Lars* (1873); *The Prophet, a Tragedy* (1874); *Home Pastorals* (1875); *The National Ode* which he was chosen to deliver at the Centennial Exhibition (1876); *Prince Denkulon*, a drama (1878); and an admirable translation of *Faust* (1870-71). He also wrote several novels, the best *Hannah Thurston* (1863) and *The Story of Kennett* (1866). See his *Life and Letters* (2 vols. 1884).

Taylor, BROOK, mathematician, was born of good family at Edmonton in Middlesex, August 18, 1685, and studied at St John's College, Cambridge. In 1715 he published his *Methodus Incrementorum Directa et Inversa*, the foundation of the Calculus of Finite Differences. Herein also is the formula which, as 'Taylor's theorem,' will keep his name from ever being forgotten. In 1716 he visited Paris and was warmly received by the French savants. From 1714 till 1718 he acted as secretary to the Royal Society. His last years were given to speculations in philosophy and religion, and were darkened by the early deaths of two successive wives. He himself died December 29, 1731. Other works were a *Treatise on Linear Perspective* (im-

proved ed. 1719) and the posthumous *Contemplatio Philosophica* (edited by his grandson, Sir W. Young, with Life, 1793). Several short papers may be found in the *Phil. Trans.* (1713-23).

Taylor, Sir Henry, poet, was born, the son of a gentleman-farmer of unusual culture, at Bishop-Middleham in Durham, October 18, 1800. At fourteen he went to sea as midshipman, but was happy to obtain his discharge after nine miserable months, and two years later was given a clerkship in the Storekeeper-general's Department. After four years' service, including a few months in Barbadoes, he lost his post through internal official rearrangements, and returned to his father's house, Wilton Hall, to spend two years of uninterrupted quiet and study. He began to write for the *Quarterly*, and in 1823 settled in London, having been appointed through the influence of Dr (after Sir Henry) Holland to a clerkship in the Colonial Office. Here he laboured for forty-eight years under as many as twenty-six secretaries of state, retiring only in 1872. He declined in 1847 the post of permanent under-secretary in succession to Sir James Stephen, and in 1869 was made K.C.M.G., partly for his public services, partly for his literary work—the latter also acknowledged by the D.C.L. degree at Oxford in 1862. His last days were spent at Bonnemouth, and here, March 27, 1886, he ended a long and happy life, the happiness of which was in great measure due first to his admirable step-mother, later to his equally admirable wife, Alice Spring Rice, a daughter of Lord Monteagle. Taylor wrote four tragedies in the Shakespearian manner: *Isaac Commencus* (1827), *Philip van Artevelde* (1834)—an immediate success, *Edwin the Fair* (1842), and *St Clement's Eve* (1862); and one romantic comedy, *The Virgin Widow*, afterwards entitled *A Sicilian Summer*. In 1845 he published a small volume of lyrical poetry, and in 1847 *The Eve of the Conquest and other Poems*. His work in prose embraced *The Statesman* (1836), a collection of Baconian discourses on official life and the methods of managing men, for which, as he himself says, 'Pragmatic Precepts' would have been a better title; *Notes from Life* (1847)—one of its essays, *The Life Poetic*, mainly a eulogy of Southey; and *Notes from Books* (1849), half made up of two articles on Wordsworth. Last came his interesting *Autobiography* (2 vols. 1885), admirably written, full of genial observation, and not marred at all by the pardonable egotism of age and merit. It contains a fine series of pen-portraits of such contemporaries as Wordsworth, Southey, Scott, Sydney Smith, Mill, Sir James Stephen, Spedding, Carlyle, Tennyson, and Aubrey de Vere. It was supplemented by his only less delightful *Correspondence* (1888), a selection of 202 letters, edited by Professor Dowden, including also letters to Taylor, from Wordsworth, Southey, Stephen, Mrs Norton, Macaulay, Spedding, Tennyson, Aubrey de Vere, Gladstone, Mr John Brown, and Swinburne. A uniform collected edition of his works had appeared in 5 vols. in 1878.

Taylor, Isaac, writer of many books on religious and philosophical subjects, was born at Lavenham in Suffolk in 1787. His father, Isaac Taylor the first (1759-1829), was originally a London engraver, but in 1796 became Independent minister at Colchester, in 1811 at Ongar in Essex, and published a score of volumes. Charles Taylor (1756-1821), editor of Calnet's *Bible Dictionary*, was an uncle, and two sisters were Jane Taylor (1783-1824), author of the *Contributions of Q.O.*, and Ann Taylor (Mrs Gilbert of Nottingham, 1782-1866; *Autobiography*, 1871), joint-authors of the famous *Hymns for Infant Minds and Original Poems*. After a course of study he settled down

to a busy literary life at Ongar, where he died, June 28, 1865. As early as 1818 a writer in the *Eclectic Review*, he lived to contribute to *Good Words*—a period of over forty years. In 1862 he was granted a Civil List pension of £100. Of his many books the most important were the *Natural History of Enthusiasm* (1829), *The Natural History of Fanaticism* (1833), *Spiritual Despotism* (1835), *Physical Theory of Another Life* (1836), and *Ultimate Civilisation* (1860).—His eldest son, ISAAC TAYLOR, was born at Stanford Rivers, May 2, 1829, had his education at Trinity College, Cambridge, took orders, and after acting as curate in London and elsewhere, and as vicar of St Mathias, Bethnal Green (1865-69), and Holy Trinity, Twickenham (1869-75), was presented to the rectory of Settrington in Yorkshire in 1875, and collated to a canonry of York in 1885, becoming dean two years later. His *Words and Places* (1864) made him favourably known as a philologist, whilst his great work, *The Alphabet, an Account of the Origin and Development of Letters* (2 vols. 1883; new ed. 1899), brought him a wide reputation. Other publications are *The Family Pen*; *Memorials of the Taylor Family of Ongar* (2 vols. 1867); *Etruscan Researches* (1874); *Greeks and Goths, a Study on the Runes* (1879); *The Origin of the Aryans* (1890); and *Names and their Histories* (1895)—besides contributions to the learned journals, and philological articles in former editions of this work. He died in October 1901.

Taylor, JEREMY, the glory of the English pulpit, was the third son of a Cambridge labourer, and was born very probably in that town, and baptised in the Holy Trinity Church there on 15th August 1613. At thirteen he entered Caius College as a sizar, graduated B.A. in 1630-31, and, according to his friend and successor Bishop Rust, was thereafter chosen fellow of his college. At any rate he became M.A. in 1633, about the same time being admitted to holy orders, and soon after he attracted the notice of Laud, who had a regard for learning, if none for liberty, and was preferred through his influence to a fellowship at All Souls in Oxford (1636). He became also chaplain to the archbishop, and in 1638 was presented by Bishop Juxon to the rectory of Uppingham. About this time Wood tells us he was suspected by watchful zealots of a concealed attachment to the Romish communion, whether from his ascetic notions of piety, his veneration for antiquity and love for the picturesque aspects of religion, the favour of Laud, or his friendship with the learned and pious Franciscan friar, Francis a Sancta Clara [Christopher Davenport]. Taylor married Phoebe Landisdale, or Langsdale, in 1639; his second wife, Joanna Bridges, was believed by Bishop Heber, chiefly on the somewhat questionable authority of the MS. of Mr Jones, a descendant of Taylor's, to have been an illegitimate daughter of Charles I. when Prince of Wales. His *Episcopacy asserted against the Acephali and Acrians New and Old* (1642) scarcely gave promise of his future powers, but gained him the empty honour of a D.D. degree. During the struggle Taylor is supposed to have accompanied the royal army as a chaplain, but about the close of 1643 we find him living with his mother-in-law and children, and embarrassed by poverty. Heber thought his first wife was already dead, and that soon after this time he married his second, and retired to her property at Mandinam in Caernarthenshire. It seems probable, however, that his first wife did not die till 1651. At any rate, after the downfall of the cause he found a shelter in Wales, and for some time he joined in keeping a school at Newton Hall in the parish of Llanfihangel. Here he found a kind patron in Richard Vaughan, Earl of Carbery, then living at the family seat of

Golden Grove, immortalised in the title of Taylor's still popular manual of devotion (1655). His second countess was Alice, daughter of John Egerton, first Earl of Bridgewater, and the original of the 'lady' in Milton's *Comus*. During the last thirteen years (1647-60) of Taylor's enforced seclusion appeared all his great works, some of these the most enduring monuments of sacred eloquence in the English language. The first was *The Liberty of Prophesying* (1647), a noble and comprehensive plea for toleration and freedom of opinion, far above the ideas of its age, and even of its author in his turn of triumph. Here he takes the Apostles' Creed as the minimum standard of Christian communion, the only necessary terms of such being those dogmas that are capable of being propounded *infallibly*; that is, from Scripture, in the due exercise of Reason, all such errors as may arise being necessarily venial, when not wilful. 'Heresy is not an error of the understanding, but an error of the will,' to which proposition Coleridge aptly adds its converse, 'faith is not an accuracy of logic, but a rectitude of heart.' 'Those creeds are best which keep the very words of Scripture; and that faith is best which hath greatest simplicity; and it is better in all cases humbly to submit, than curiously to inquire and pry into the mystery under the cloud, and to hazard our faith by improving our knowledge.' He next passes in review the alleged special sources of authority in religious opinion: Scripture, Tradition, Ecclesiastical Councils, the Pope, and the Fathers, finding all save Scripture, interpreted by an enlightened reason, insufficient and contradictory. With regard to civil government he lays down broadly the principle that it is not concerned with opinions, however false or absurd, unless these tend directly to the prejudice of government as such, thus demanding the widest toleration for honest opinion ranging from Anabaptism to Popery. The second edition (1659) closes with the celebrated story of Abraham and the idolatrous traveller.

In 1650 followed the *Life of Christ*, or the *Great Exemplar*—an arrangement of the facts in historical order, interspersed with prayers and discourses on topics suggested by the narrative. That same year appeared *The Rule and Exercises of Holy Living*, followed in 1651 by its counterpart, *The Rule and Exercises of Holy Dying*, together forming to generation after generation the choicest classic of English devotion. The twenty-seven *Sermons* for the summer half-year were published in 1651; the twenty-five for the winter half-year in 1653. These, with the discourses in the *Life of Christ* and many passages in the *Holy Living* and *Dying*, contain the richest examples of their author's characteristically gorgeous eloquence. The polemical and practical treatises are more subdued in style, though still figurative and allusive far beyond the measure even of his contemporaries; but here he gave full reins to an imaginativeness unmatched alike in range of illustration and in opulence of language. The solemn music of his words, the rich beauty of the imagery in his incidental metaphors, the tenderness, passion, colour, and force, if not precision, of phrase combine to place these writings by themselves on a level scarce attained by all the Asiatic eloquence of Chrysostom.

The more formal treatises were *An Apology for Authorised and Set Forms of Liturgy against the Pretence of the Holy Spirit* (1646); *Clerus Domini, or a Discourse of the Divine Institution, Necessity, Sacredness, and Separation of the Office Ministerial* (1651); *The Real Presence and Spiritual of Christ in the Blessed Sacrament proved against the Doctrine of Transubstantiation* (1654); *The Unum Necessarium, or the Doctrine and Practice of Repentance* (1655), a

treatise with a decided taint of Pelagianism, where the theologian had ventured beyond his depth, and which involved him in a cloud of controversy; *The Worthy Communicant* (1660); *Defence and Introduction to the Rite of Confirmation* (1663); *The Dissuasive from Popery* (1664); and the famous *Ductor Dubitantium, or the Rule of Conscience in all her General Measures* (1660), the most learned and subtle of all his works, which he himself counted on as the foundation of his fame. Intended as a complete handbook of Christian casuistry and ethics, it labours first to establish a system of morality on the basis of the will of God revealed to us through Conscience, distinguishing with greater subtlety than security the right or sure conscience, the conscience confident in error, the probable or thinking, the doubtful, and the scrupulous conscience. Under the 'probable' head he gives a magnificent sketch of the different probabilities on which a faith in Christianity is founded. The second book discusses the obligations of conscience in relation to the law of nature and the law of Christ, closing with a splendid peroration on the measures and motives of a Christian's duty. In the third book he passes to human positive law alike of church and state, and in the fourth—the best part of the whole—he closes with a discussion of the nature and causes of good and evil, and the efficient and final causes of human actions. But Taylor is much more a rhetorician than a thinker or even a theologian, and his imagination too often carries him at a leap from an illustration to an argument, from an analogy to a conclusion. Distinctions without a difference, inconsistencies, sophistries, and prolixity are foibles that too easily beset his argument, and go far to mar the effect of vast erudition, subtlety of thought, and dazzling eloquence. Besides the real bases of the controversy have shifted far from the 17th-century landmarks, and much of his subtlest argument is to modern men a mere beating of the air. Nor is he altogether free from the special sin of casuistry in its narrowest sense—he maintains that private evil may be done for the public good, that in controversy it is allowable to employ arguments and authorities we know to be invalid, and he is able to justify on moral grounds the fraudulent Israelitish borrowing from the Egyptians. He is besides much too slavish in his respect for authority and tradition, but, as Coleridge says well, Jeremy Taylor 'would have been too great for man had he not occasionally fallen below himself.'

During the troubles Taylor was thrice imprisoned, once for the preface to the *Golden Grove*; the last time in the Tower for an 'idolatrous' print of Christ in the attitude of prayer in his *Collection of Offices* (1658). He occasionally visited London, where he numbered among his friends John Evelyn, to whom he wrote many admirable letters still extant, as well as Boyle, George Berkeley, afterwards first Earl of Berkeley, and Wilkins. In 1658 he was given by the Earl of Conway a lectureship at Lisburn in Ireland, and at the Restoration he was made bishop of Down and Connor, to which was added the administration of the see of Down. By Ormonde's recommendation he was elected vice-chancellor of the university of Dublin, and in February 1661 he was admitted a member of the Irish privy-council. There were many stubborn Presbyterians in his diocese who mocked at his authority, and tormented his gentle spirit, but we need not believe that the plot to take his life existed anywhere else than in his active imagination. In his first visitation he ejected thirty-six of them from their churches, but neither severity nor gentleness could prevail to force a form of religion upon an unwilling people. His last years were clouded also by domestic sorrows. His eldest son,

an officer in the army, was killed in a duel; the second passed from Trinity College to become the favourite companion and secretary to Buckingham, and died a few days before his father. The three daughters of his second wife alone survived him. He died at Lishurn after a ten days' fever, 13th August 1667, and was buried in the choir of the cathedral at Dromore, largely rebuilt by his own munificence.

Jeremy Taylor's beauty of person corresponded to the beauty of his character and the large charity of his temper. Good portraits are abundant, several he himself gave as frontispieces to his writings; one of the best hangs in All Souls College, Oxford. Bishop Heber endorses Parr's description of Hooker as the object of our reverence, Barrow of our admiration, but Jeremy Taylor of our love. He was above all things a preacher, and that especially of personal holiness. The thread of ideas is ever clear and simple underneath all his exuberant fullness and the stately march of his sentences, and though it is difficult to conceive of a congregation capable of following his argument and illustration in their full detail, all the haste and indistinctness of argument, the quaint, pedantic, and even grotesque irrelevances of illustration are fused together into harmony in the orator's glowing earnestness and fire. No poet ever excelled Jeremy Taylor in exquisite feeling for the sights and sounds of nature; he has no rival in lofty and impassioned prose save Milton alone—'Most eloquent of divines,' says Coleidge, 'had I said of men, Cicero would forgive me, and Demosthenes nod assent.'

The first collected edition of his works was that of Bishop Heber, with an excellent life (15 vols. 1820-22); a revised edition by the Rev. C. P. Eden (10 vols. 1847-54). See Coleridge's *Literary Remains*, vol. iii. (1838); Tulloch's *Rational Theology in England in the Seventeenth Century*, vol. i. (1872); Dean Farrar in *Masters in Eng. Theology* (1877); Bishop Barry in *Classic Preachers of the Eng. Church*, series ii. (1878); the *Quarterly Review* for July 1871; and Gosse's study in the 'English Men of Letters' series (1904) and W. J. Brown's in the 'English Theologians' series (1925).

Taylor, JOHN, the 'Water-poet,' as he styled himself, was born at Gloucester in 1580, and became a waterman on the Thames, but was pressed into the naval service and served at the siege of Cadix. He collected for many years for the lieutenant of the Tower his perquisite of wine from all ships which brought wine up the Thames. When the rebellion broke out in 1642 Taylor left London for Oxford, where he kept a public-house, which he afterwards gave up for another in London, and here he hawked the doggerel which he wrote. He performed some fantastic feats of rowing, but the chief event of his life was his journey on foot from London to Edinburgh (14th July—13th August 1618). Ben Jonson thought the Water-poet's intention was to burlesque his own journey, yet when he met him at Leith he gave him a piece of gold to drink his health in England. Taylor described his journey in his *Penultima Pilgrimage* (1618); other books of the same kind were his *Travels in Germany* (1617) and *The Praise of Hempseed*, a story of a voyage from London to Queenborough in Kent in a brown paper boat (1618). He died in 1654. Taylor's works were published under the title of *All the Works of John Taylor the Water-poet, being sixty and three in number* (1630, folio). His poems are not destitute of natural humour, abounding with the low, jingling wit which prevailed in the reign of James I., and which too often bordered upon bombast and nonsense. Allibone's *Dictionary* contains a list of 138 articles written by the Water-poet. The best reprint of his works is a complete edition issued by the Spenser Society (1868-78).

Taylor, NATHANIEL WILLIAM, preacher and theologian, was born at New Milford, Connecticut, 23d June 1786, studied at Yale, became pastor of a Congregational church at New Haven in 1812, and in 1822 became professor of Theology in Yale College, where he taught until his death, 10th March 1858. In numerous sermons, lectures, and essays he maintained what from his pastoral charge became known as the 'New Haven theology,' long assailed as heretical. This system, a softening of the traditional Calvinism of New England, maintained the doctrine of natural ability, and denied total depravity; sin is a voluntary action of the sinner; but there is, derived from Adam, a *bias* or *tendency* to sin, which is not itself sinful. His works were edited in 5 vols. by his son-in-law, Dr Noah Porter (1858-59).

Taylor, PHILIP MEADOWS, Indian administrator and author, was born at Liverpool 25th September 1808, held a mercantile post in Calcutta, but obtained a commission in the army of the Nizam of Hyderabad, whom he served from 1826 as administrator of various large territories, one of them the tributary state of Sheapur. In this capacity he showed marvellous insight, tact, and kindness, establishing order and justice in place of mere barbarous tyranny, and maintained peace during the mutiny of 1857. The British government gave him charge of some of the ceded districts; in 1866 he retired colonel and C.S.I.; and he died at Mentone, 13th May 1876. He left vivid pictures of Indian history, life, and manners in his romances, *Confessions of a Thug* (1839; new ed. 1858); *Tippoo Sultan* (1840); *Tara* (the story of Sivaji, 1863); *Ralph Darnell* (1865); *Seeta* (1873); and *A Noble Queen* (1878). See his *Story of my Life*, edited by his daughter (1877; new ed. 1920).

Taylor, ROWLAND, Marian martyr, was a native of Rothbury in Northumberland, and studied at Cambridge, taking his LL.B. in 1530 and LL.D. in 1534. Cranmer, to whom he was domestic chaplain, gave him the rectory of Hadleigh in Suffolk (1544), and he subsequently became archdeacon of Exeter (1551) and a canon of Rochester. Under Mary he was imprisoned as a heretic for more than a twelvemonth in the King's Bench, and on 8th February 1555 was burned near Hadleigh. See Cooper's *Atheus Cantabrigiensis* (1858).

Taylor, THOMAS, 'the Platonist,' was born in London, 15th May 1758, went three years to St Paul's School, next studied mathematics and classics under private teachers, but, betwixt an imprudent marriage and the pinch of poverty, found it impossible to realise his dream of completing his studies at Aberdeen with a view to the ministry, and entered Lubbock's bank as a clerk. But he still found six hours in every day for study, and at length left his desk to teach private pupils and fill the office of assistant-secretary to the Society for the Encouragement of Arts, &c. During his last forty years he lived in a small house at Walworth, immersed in Plato and the Platonist philosophers, and partly supported by a gift of £100 a year from Mr Meredith, a retired tradesman with ideas, and there he died, 1st November 1835. His fifty works include translations of the Orphic Hymns, and parts of the works of Plotinus, Proclus, Pausanias, Apuleius, Maximus Tyrius, the Greek mathematicians, Iamblichus, Hierocles, Porphyry, &c., besides complete translations of Plato (nine, however, of the *Dialogues* by Floyer Sydenham, 5 vols. 1804) and Aristotle (11 vols. 1806-12). Mr W. E. A. Axon in a biographical and bibliographical sketch (privately printed, 1890) gives a list of forty-eight books, but does not include *The Spirit of All Religions* (Amst. 1790), which expresses his strange polytheistic creed.

Taylor, TOM, journalist and playwright, was born in 1817 at Sunderland, and passed from the Grange School there in 1831 to Glasgow University, and thence in 1837 to Trinity College, Cambridge, where he graduated as third classic in 1840, and was elected to a fellowship. Professor for two years of English language and literature at University College, London, he was called to the bar of the Inner Temple in 1845, for a short time travelled the northern circuit, and from 1850 to 1872 was first assistant-secretary and secretary to the Board of Health, and then secretary to the Local Government Board. From about 1846 onwards he wrote or adapted upwards of a hundred pieces for the stage, of which may be mentioned *Our American Cousin*, *Still Waters Run Deep*, *The Ticket of Leave Man*, and *Twist Axe and Crown*. He also edited the autobiographies of Haydon and Leslie, completed the latter's *Life and Times of Reynolds*, translated *Ballads and Songs of Brittany* (1865), and in 1874 succeeded Shirley Brooks as editor of *Punch*. He died at Wandsworth, 12th July 1880.

Taylor, WILLIAM, 'of Norwich,' was born there in 1765, the only son of a rich Unitarian merchant, and was educated at Palgrave by Mrs Barbanild's husband. At fourteen he entered his father's counting-house, but next year was sent on the first of two visits to the Continent, where he mastered French, Italian, and, more especially, German. The French Revolution at once inculturated him with democratic ideas and began the ruin of his father's business, which by 1811 was completed by American 'repudiation' and a stock-broker's bankruptcy; Taylor had meanwhile turned wholly from commerce to literature. His is the credit of introducing to English readers the poetry and drama of Germany, mainly through criticisms and translations contributed to periodicals, and collected in his *Historic Survey of German Poetry* (3 vols. 1824-30). Other works by him were *English Synonyms Discriminated* (1813) and a *Life of F. Schlegel* (1823). He died at Norwich in March 1836. George Borrow, his pupil in German, has sketched in *Lancashire* his philosophy, scepticism, and inveterate tobacco-smoking; and his correspondence with Southey, Scott, Mackintosh, and Godwin is given in the memoir of him by Robbards (2 vols. 1843). See also the (German) monograph on him by Georg Herzfeld (1897).

Taylor, ZACHARY, a distinguished general and twelfth president of the United States, was born in Orange County, Virginia, 24th September 1784. His father had been a colonel in the war of independence, and removed to Kentucky in 1785, settling near Louisville. Here Zachary lived on a plantation until 1808, when he entered the army as lieutenant. In 1812 as captain he commanded Fort Harrison on the Wabash, and in September with only fifty men, two-thirds of whom were on the sick-list, successfully defended that post against a large body of Indians. After further service on the north-western frontier Taylor became major, but at the close of the war being reduced to a captaincy he resigned his commission. He was soon reinstated and again employed against the Indians, and in 1832 fought with Black Hawk, the noted chief of Illinois. In 1836 Taylor, now colonel, was ordered to Florida, where previous commanders had suffered in reputation from their vain attempts to subdue the troublesome Seminoles. Taylor had the good fortune to defeat the savages at Okeechobee Swamp on Christmas Day 1837, and thus won the brevet of brigadier-general. In 1840, being placed in command of the army in the south-west, he removed his family to a plantation at Baton Rouge, Louisiana.

When Texas was annexed in 1845 its western

boundary was not defined, and Mexico still claimed the uninhabited district between the Rio Grande and the Nueces. Taylor, being ordered to defend Texas from invasion, sailed from New Orleans to Corpus Christi, where he gathered a force of 4000 regulars. Though well aware that President Polk wished him to occupy the disputed district, he would not cross the Nueces until express orders came in March 1846. He then marched to the Rio Grande and erected Fort Brown opposite the Mexican town of Matamoros. The Mexicans ordered him to retire, and upon his refusal crossed the Rio Grande to drive him out. Their action enabled President Polk to declare that the United States had been invaded, and to call for volunteers to repel the foe. But the battles of Palo Alto and Resaca de la Palma on the 8th and 9th of May drove the Mexicans back, and Taylor following seized Matamoros. The volunteers did not come to his aid until September, when he marched to Monterey, and after a severe struggle captured it on the 24th. After seven weeks' vain waiting for more troops the march was resumed. The city of Victoria was occupied on December 29, but the line of communication was found too long for the meagre force, while Polk's Democratic administration, fearing the rising fame of Taylor, who was a Whig, crippled him by withholding reinforcements.

Taylor was already falling back to Monterey when his regulars were taken from him to form part of the new expedition under General Scott. Santa Anna, the ablest Mexican general, learning of Taylor's weakened condition, believed that with his 21,000 veterans he could crush the 5000 American volunteers. After a march of hundreds of miles, he overtook Taylor near the mountain pass of Buena Vista. Availing himself of its natural advantages, Taylor on the 22d of February 1847 completely repulsed the Mexicans with a loss thrice as great as his own. In the following November General Taylor returned home and was received with enthusiastic expressions of popular favour. In June 1848 the convention of the Whig party, passing by its great political leaders, selected him as the candidate for the presidency. A few Free Soilers refused to support him as being a slaveholder, but his character, indicated by the sobriquet of 'Rough and Ready,' endeared him to the masses. He was triumphantly elected in November and inaugurated in the following March. The fierce struggle over the extension of slavery to the newly-acquired territory had begun. The congress was Democratic and opposed the admission of California as a free state, while the president favoured it. To avert the threatened danger to the Union Henry Clay introduced his famous compromise, which called forth a stormy discussion. Taylor remained firm and impartial, though his son-in-law Jefferson Davis was the leader of the extreme pro-slavery faction. Before a decision was reached in congress President Taylor died suddenly of bilious fever, 9th July 1850.

General Taylor was of medium height, stout and swarthy. He was plain in manners and speech, and careless in dress; he rarely wore uniform, and often sat sideways on his horse. His ability as a commander is shown by his unvarying success in battle, and is attested by General Grant, who served under him as lieutenant. Though Taylor had taken little part in political strife, he carried off the prize which great party leaders failed to win. As president he showed himself a true promoter of his country's welfare. There are Lives by Frost (1848), Fry and Conrad (1848), and O. O. Howard (1892).

Tayport, a watering-place and police-borough of Fife, on the Firth of Tay, opposite Broughty-Ferry (q.v.): pop. 3300.

Tchad, LAKE. See TSAD.

Tchakovsky. See TSCHAIKOVSKY.

Tchelyuskin. See CHELYUSKIN.

Tcherkask (Old Tcherkask), a town of South Russia, formerly the capital of the Don Cossacks, on the right bank of the Don, 12 miles S. of Novotcherkask (q.v.); pop. 15,000.

Tcherkasy, or TCHERKASK, a town of Ukraine, 90 miles by rail SE. of Kieff, on the Dnieper; pop. 32,000.

Tcherkesses. See CIRCASSIANS.

Tchernavoda, a town of Rumania on the Danube, connected with Kustendji by rail, and having over the Danube a great steel cantilever bridge 2878 metres long; pop. 5000.

Tchernigoff, or CHERNIGOV, a town of Ukraine, 85 miles NE. of Kieff; pop. 37,000.

Tchernozem. See BLACK EARTH.

Tchernyshevsky, NIKOLAI GAVRILOVITCH (1828-89), nihilist. See NIHILISM.

Tchita. See CHITA.

Tea (*Camellia theifera*, Griff.) is a plant of the genus *Camellia* (q.v.), by some placed in a separate genus *Thea*, of the family Theaceae or Ternstroemiaceae. There are two well-known varieties: (1) *C. theifera*, var. *assamica*, or Assam tea; and (2) *C. theifera*, var. *sinensis*, or China tea. The Assam variety, known as 'indigenous' tea, is a tree of vigorous growth attaining a height of 30 to 40 feet, with a leaf from 8 to 10 inches in length. The China variety is a comparatively

China Tea (*Camellia theifera*), young shoot with flowers: a, fruit. (Hentley and Trimen.)

stunted shrub, though hardier, growing to a height of 12 to 15 feet, with a rounder leaf about 3½ inches in length, and calyx covered with soft short hairs. There is no evidence that tea is wild in any part of China or anywhere else except in the forests of Assam; some think that the Chinese variety is the indigenous, changed by climate and cultivation. These two varieties have resulted in a hybrid which combines the hardy character of the China with the other features of the indigenous, now largely cultivated on the hills

of India and Ceylon, and known as 'hybrid Assam.' At low elevations where the climate is tropical the indigenous, or a hybrid nearly approaching it, is preferred. The hybrids vary much in productiveness, and the planter is careful in selecting a good strain, which grows and foliates freely without seeding. The branches are smooth. The leaves are serrated, have a bright shining upper surface, and, while young, a hairy under surface. They are rather thin, but often tough and leathery. In the substance of the leaf are located large smooth cells containing an essential oil, of great importance to the flavour of the tea. The flowers are often handsome, usually white, and are about 1½ in. in diameter; sometimes solitary, sometimes clustered in masses; they have very short flower-stalks or no stalks at all. The fruit is rather short, of a leathery or woody consistency; dry, not fleshy. Inside it is divided into three, four, or five three-celled chambers. Linnaeus gave the name *Thea sinensis* to the Chinese variety, but afterwards made two species, *T. bohea* and *T. viridis*, under the impression that black and green tea were the products of different plants. Robert Fortune (q.v.), the botanist, was the first to show that both kinds of tea were made from the same shrub. *T. bohea* and *T. viridis* are names now applied respectively to the China and Assam varieties. The Chinese name for tea is *tscha*, in the Fuh-kien dialect *té* or *teh*.

The tea-plant is not particular as to soil, but it succeeds best on new forest-land containing plenty of humus. It will flourish in all parts of the tropical and subtropical zones where the rainfall is not less than 70 inches and evenly distributed throughout the year. In Ceylon (lat. 7° N.), it grows from sea-level to an altitude of 7000 feet. At a low elevation the growth of the plant is more rapid, but in time the high-grown tea seems to produce as much leaf as the average of low-country estates, while the tea is of more delicate flavour, though inferior in strength. At Dārjiling (27° 3' N. lat.) it grows at 7000 feet above sea level. In China and Japan it is cultivated to the 40th degree N. lat. Tea also grows in Java, Sumatra, Nyasa land, Georgia (Caucasus), northern Siam, Kenya, and Natal, and attempts have been made to introduce the plant into Brazil. A point of some importance in the distribution of the industry is that tea-growing requires abundant cheap labour. Thus a country where labour is dear cannot for long compete with one where labour is cheap. In Natal, for instance, tea-growing is being abandoned owing to the high cost of labour, and in the United States, for a similar reason, tea culture never progressed past the experimental stage. Indeed, the labour difficulty is at present confronting the Indian industry.

Cultivation.—The clearing is made by cutting the undergrowth with heavy socket-knives, after which the forest-trees are felled and the largest branches lopped; six weeks afterwards the wood is burned. Tea is planted in rows from 3½ to 5 feet apart, with a similar distance between the plants; 4 × 4 feet being a favourite distance, which gives 2722 plants to the acre. The tea-seed is soaked in water, and planted in shaded nursery beds; when the plants are about 4 inches high they are transplanted to the holes in wet weather during the monsoons. When plants are scarce the seed may be sown at stake in the holes, but nursery plants are generally preferred. The clearing is roaded and drained as soon as possible. On the rich deep soils of Assam manuring is not practised. In Ceylon the favourite manures are cattle-dung, castor-cake, bones, nitrogenous manures, and those which contain potash. When the plants have been in the ground about fifteen

to eighteen months they are cut down to 10 or 12 inches; this makes them spread, and strengthens the growth of the branches. In about two months the more vigorous shoots are nipped back below the second leaf, thus taking off the terminal leaf-bud and first and second leaves, which makes the axillary bud at the base of the third leaf develop a fresh shoot. At first plucking is rather a matter of pruning than of gaining leaf, but as the trees become stronger the plucking becomes more regular and heavier. At about three years the bush is again cut down to some 15 inches flat across, so as to leave two joints of new wood above the last pruning. In subsequent prunings all bark-bound wood must be removed, along with whippy branches which do not 'flush' or develop fresh shoots. The plucking is done with the thumb-nail, and the leaf must on no account be torn off. Only the youngest and most tender leaves are plucked; and the younger the leaf, the finer the tea. The largest leaves used are never more than 2½ inches long. The estate must be plucked in regular rotation every ten days or a fortnight. When tea is flushing well a good coolie can bring in from 20 to 30 lb. of green leaf in a day.

In China the system of tea cultivation is very different from that practised in India and Ceylon, the use of machinery still being very exceptional. There are no large estates, the tea being grown in small fields and gardens, often situated on hillsides. The leaf is plucked from the latter part of April to the end of October, the small farmer importing coolie labour for the purpose from the more populous districts. The grower does not manufacture the leaf himself, but sells it green in the local market at the nearest head village. The green leaf is bought by the agents of Chinese capitalists, who have honghs where they manufacture and pack the leaf. Finally the hong-man ships the tea in boats, and sends it down the rivers. Until 1919 exported tea was subject to an export duty which through time proved exceedingly oppressive.

Chinese teas may be classified thus: Monings or black leaf teas are grown in the north of China, and shipped from Hankow and Shanghai. They come from the following districts: Ningchow (mostly bought for Russia), Kintuck, Keemun (shipped chiefly to England), Kutoan, Ichang, Onack, Onann, Onfa, Ly Ling, Cheong-sow-kai, Hohow, Siangtan. Green teas are shipped from Shanghai, and consist of Gunpowder, Imperial, Hyson, Young Hyson, and Twankay. Kaisows or Red-leaves are grown farther south, and are shipped from Fu Chow. The different kinds, which take their names from the districts in which they are grown, are Seumoo, Panyong, Paklin, Pakling, Padrae, Saryane, Suey Kut. From Fu Chow are also shipped Souchongs, which are a distinct kind from Congons, and are principally drunk in Germany and Austria. Fancy teas, consisting of Oologs, Flowery Pekoes, and Scented Orange Pekoes, are exported from Fu Chow. Canton exports Congons called New-makes, Scented Capers, and Scented Orange Pekoes. The perfume of the scented varieties usually comes from aromatic leaves—jasmine, gardenia, &c.—used in the manufacture.

Manufacture.—The first process is to spread the green leaf thinly on hessian trays in the withering house, where it is exposed to a free current of air—a very important operation, which takes from 12 to 48 hours. Withering is assisted by fans which circulate currents of dry air. When the leaf is tough and flaccid, like an old kid glove, it is ready for rolling. The old or Chinese system of rolling was to place the withered leaf on a table

where it was rolled by hand to and from the coolie till the juice was expressed and the leaf well twisted; this took about 20 minutes to do. The Chinese accomplish this partly by the dirty process of treading. Now this process is performed by machinery, and in India and Ceylon tea is not manipulated after plucking. In the tea-rolling machines in general use in India and Ceylon, the leaf is rolled between two superposed plates of hard wood or polished granite, actuated by cranks which give them a compound circular or eccentric motion. These machines are capable of taking a charge of 240 to 300 lb. of withered leaf; they are driven by steam, water, or electric power, effect great saving in labour, do the work more thoroughly, and ensure perfect cleanliness. Some planters sift the rolled leaf through sieves with ½-inch meshes and re-roll the leaf which is too large to pass through. Considerable diversity of opinion exists as to whether tea should be rolled lightly or hard: the former gives a prettier tea with more of the golden 'tip'; the latter gives a stronger liquor, and the tea keeps better. The rolled leaf is now ready for fermentation, an operation requiring close attention. It is placed in drawers or on tables and covered. The state of the weather hastens or retards the process; in hot dry weather the leaf will be sufficiently fermented or oxidised in 20 minutes, in cold wet weather it may take hours. When the leaf assumes a bright copper colour it must be fired; over-fermentation is a fatal error. The difference between black and green teas is simply this: if the tea is fired immediately after rolling it is green tea, if it is fermented it becomes black tea. In green tea, also, the fresh leaves are steamed instead of being withered. The old system of firing was to have iron gauze trays fitting over V-shaped chula furnaces about 30 inches high, and to dry the tea over charcoal fires. Now drying is done quicker and better by machines for the purpose, such as the 'Sirocco' or Venetian, consisting of a stove portion and drying chamber, through which a powerful air-current passes; and by this means the wet leaf is dried thoroughly in 6 to 8 minutes. Various machines are in use. After firing the manufacture is complete, and the tea is what is known as 'unsorted', which contains all the different grades into which tea is usually separated. In this state it is a most excellent tea for drinking, but it is customary to sort it into different grades before sending it to market. The old system of doing this was by using hand sieves of different sizes. The 'dust' was taken out by the finest sieve; the 'broken pekoe' or finest and youngest leaf by the next; the 'pekoe' by a sieve with wider meshes; the 'pekoe sonchong' by the next larger; if 'sonchong' is made a still larger meshed sieve is employed. Sorting by hand sieves is still done in small factories, but combined sorting and cutting machines are used in the larger factories. Before the final packing the tea is taken from the bins in which it is kept and re-dried to expel any moisture which it may have absorbed from the atmosphere. It is then weighed into lead-lined chests, half-chests, or boxes, and soldered up, the name of the garden is stencilled on the packages, and it is exported as soon as possible to prevent loss of flavour. Chests usually contain 100 lb. of tea, half-chests from 45 to 60 lb., and boxes 20 lb. The 'brick tea' prepared at Hankow for overland exportation to Russia is made of tea-dust steamed and pressed into cakes, which occupy only one-sixth of the bulk of loose tea. A coarser kind, made of tea-leaves, stalks, and refuse of the tea-dust cakes, is sent to Mongolia, where for use it is boiled with mutton fat and butter. Pickled tea is used for chewing by the Siamese, and eaten with fish by the Burmese.

History.—Fable has it that the Chinese drank tea in the time of the Emperor Chi Nung (2737 B.C.), and it is mentioned in a work edited by Confucius about 500 B.C. Its early use is thought to have been medicinal, but when a certain Lo Yu wrote a dissertation on tea in 780 A.D. it was well established as a popular beverage. Various forms of brick tea seem to have been in very common use about the 9th century. Tea first became known to Europeans about the end of the 16th century. Small quantities were brought by the Dutch East India Company to England early in the 17th century, but it was not till about the year 1657 that it began to be used as a beverage, when Garraway opened a tea-house in Exchange Alley; the price then was from £10 to £5 per lb. Pepys, writing on 28th September 1660, says: 'I did send for a cup of tee (a China drink) of which I had never drank before.' Two years later he writes: 'Home, and there find my wife making of tea, a drink which Mr Pelling the Potlicary tells her is good for her cold and defluxions.' Until 1834, when it lost the monopoly of the eastern trade, the English East India Company was the sole legitimate importer of tea. In 1678 the Company imported 4713 lb.; in 1725 370,323 lb. were drunk in England; in 1740 the prices ranged from 7s. to 24s. per lb. Social reformers and others came to regard tea-drinking among the lower classes as a vice to be eradicated. Colbette called it a 'troublesome and pernicious habit.' Nevertheless it continued to spread. In 1801 the consumption was 23,730,150 lb. Since 1840 the consumption in the United Kingdom has been (1840) 32,000,000 lb., (1860) 77,000,000, (1880) 158,571,000, (1900) 249,792,087, (1920) 392,339,000; and it increased from 1·22 lb. per head in 1840 to 8·42 in 1919. From early times tea has been a ready subject for revenue-seeking statesmen. It was taxed in China in the 8th century A.D. As regards England, one of the excise duties granted to Charles II. in 1660 was one of 8d. per gallon on infused tea. In 1698 the duty became 5s. per lb., and in 1745 was lowered further. The tea duty, a customs duty since 1834 and levied specifically since 1836, has been gradually lowered from 2s. 1d. (+ 5 per cent.) per lb. in 1840 to 4d. (general rate, 1924), although it was raised to 1s. during the Great War. Great Britain easily holds the first place among the tea-consuming nations of the world. It is followed at a long distance by the United States, Australia, Canada, Irish Free State, Holland, Russia, New Zealand, South Africa, and Germany, all these being in order of the amount of imports. London was for long the great entrepôt of the tea trade, and although much is now done by direct shipment from tea-growing to tea-consuming countries, London, with its famous Mincing Lane auctions, is still the principal tea-mart of the world.

China has always been the foremost tea-producing country; its yearly output, estimated roughly, is from 700 to 900 million lb. The Chinese established a tea staple at Canton early in the 18th century. All foreign trade in tea was done here through the native Hong or Merchant Guild, but trade became freer after the Opium Wars (see CHINA). Shanghai and Foo Chow are now also centres of export. But the greatly increased demand for the stronger Indian tea has reduced the export tea trade of China to relative unimportance. Tea is said to have been introduced into Japan from China in the 9th century A.D. The use of machinery is making but slow headway in the industry, so that Japanese tea is expensive. The present acreage is about 110,000, and yearly output about 80,000,000 lb., nearly all green tea. About one-third is exported, mostly to the United States and Canada. Oolong tea, which looks like

black tea and tastes like green, comes largely from the island of Formosa.

About 1820 the plant was discovered wild in Assam, and was again noticed in 1823. The attention of the East India Company having been called to the expediency of introducing tea into India, a commission was sent to China in 1834 for this purpose. It was, however, recalled when Dr Griffith and Dr Wallish proved tea to be growing wild in Upper Assam between the Naga and Mishini mountains on the upper part of the Brahmaputra River. The same year the Company commenced the industry at Kinnamon with plants brought from China. In 1835 the first garden in Assam was opened at Luckimpore. The first pound of Indian-grown tea was sent to London in 1836; in 1839 280 lb. were for sale there, the prices ranging from 16s. to 34s. per lb. In 1840 the Assam Tea Company was started, and the first garden of indigenous tea was planted in 1840. The value of the variety was gradually recognised; though large quantities of China plants and seed were imported in 1848 and 1851. The industry in its early days passed through many vicissitudes, but the perseverance of those engaged in the cultivation was attended by success, Indian tea now constituting 60 per cent. of the English consumption, and China tea only 3 per cent. There were in 1924 about 710,300 acres under tea cultivation in India, the leading districts being Assam (397,000), Bengal (175,500), Bihar and Orissa (2100), United Provinces (6000), Punjab (9700), Madras (41,600), Tripura (2800), Travancore (46,700). The export of tea from India in 1924-25 was 355,652,000 lb., of which about six-sevenths went to the United Kingdom.

Tea was introduced into Ceylon in 1839, but it was not till 1874-75 that the cultivation became common. On the failure of coffee from the 'leaf disease' fungus about 1881 and onwards there was a rush into tea, and the staple cultivation of the colony was changed. In 1867, 10 acres were under tea; in 1877, 2720 acres; in 1891, 223,000 acres; in 1924, 418,000 acres. The exports were (1873) 23 lb.; (1877) 2105 lb.; (1880) 162,575 lb.; (1884) 2,392,973 lb.; (1888) 23,820,723 lb.; (1890) 45,390,000 lb.; (1924) 205,000,000 lb. As in Southern India, there is no winter in Ceylon and vegetation receives no check, hence tea is made more or less in every month of the year. (See CEYLON.) The Dutch introduced tea into Java about 1827 and the industry is now of considerable importance, especially since the substitution of India for China seed. In 1924 220,000 acres were under tea, and 105,000,000 lb. were produced. Tea growing in Sumatra dates only from 1910, nevertheless there is now an annual production of 18,000,000 lb. The industry was started in Natal in 1877 and, after initial set-backs, gave great promise at the beginning of the present century. But the supply of labour has proved an obstacle, and attentions are being turned rather to sugar than tea.

China teas were formerly much adulterated with foreign leaves, various mineral substances, sand, quartz, Prussian blue, gypsum, magnetic oxide of iron, soapstone, &c. These were cleverly made up with starch so as to resemble the various kinds of tea, and were known as 'lie tea.' Infused tea-leaves, redried, were also commonly used. Thanks to the care taken in the laboratory at the London Custom House, adulteration may be said to be a thing of the past to the English consumer (see ADULTERATION).

Chemistry.—As a beverage, the refreshing qualities of tea are well known. It exhilarates the system, dispels fatigue and sleepiness, and stimulates the mental powers. These properties are

generally believed to be due chiefly to the active principle theine. Tea is also held to be rich in the water-soluble vitamin B (see VITAMINS). As a beverage it is in great favour with weak and old persons, also among the poor, who find that by using tea they consume less solid food. But if tea is used to excess it produces flatulent indigestion, increased pulsations of the heart, and nervousness; the imagination is excited, and sleeplessness follows. These conditions cause a certain degree of fatigue, which induces the patient to have recourse to tea again to brace up the system, as drunkards resort to spirits in the morning for a similar purpose. It is difficult to determine how much tea can be safely drunk daily, the effects on different constitutions being unlike. Theine (see CAFFEINE) occurs very irregularly in tea, but is found to a greater degree in Indian and Ceylon than in China and Java teas, as is shown in analyses by Dr Paul and Mr Cowley (*Pharmaceutical Journal*, November 19, 1887, and July 26, 1890). From these analyses it appeared that the theine in different kinds of dry Ceylon tea varied from 4.89 to 2.57 per cent., in Indian tea from 4.89 to 3.86, and in Chinese tea it ranged from 3.78 to 2.42.

Tannin is an important constituent of tea, which gives the astringent properties to the infusion. It is generally admitted by chemists that tannin to a great extent regulates the commercial value of tea. Those teas which are rich in tannin give a stronger and darker liquor, and are consequently in greater demand. Tannin precipitates both albumen and peptone, and in this way doubtless hinders digestion. It also stops secretion from the mucous membrane, and so retards the pouring out of the digestive products; otherwise it probably has no effect, when given in small doses as in infusions of tea, on normal persons. When tea is allowed to stand five minutes before pouring off the infusion, which is the time allowed by tea-tasters, probably only one-fifth of the tannin is extracted. But when allowed to stew a long time, as is too often the case in poor households, a much larger percentage of tannin is extracted. Though Indian and Ceylon teas contain more tannin than China teas, it does not follow that the drinker of the former absorbs more tannin into his system than the drinker of the latter, as much less Indian tea is required to make a cup of tea. The percentage of gluten in tea is of little importance. Sometimes the results of analysis are stated for gluten and at other times for albumen, of which it is a form. Albumen (and gluten) is, however, rendered insoluble by boiling water, and so probably remains entirely in the tea leaves. If any were dissolved in the infusion it would probably become a food, like white of egg, fibrin, and other albumens. The following plan of tea-making for household use is worth attention. Bring the water to the boil, but do not let it boil longer or the water hardens. Use a liberal quantity of tea, and pour over it as much water as you consider will make all the tea you require. Let it stand for three minutes and pour into a fresh (warmed) teapot. Five minutes is the longest time the water should remain on the tea (see FOOD).

An important by-product of tea in China and Japan is the oil expressed from the seeds. The oil is used in toilet preparations, for burning, and other things. Hankow is the centre of the Chinese trade.

The name tea is extended to infusions of the leaves of many other plants throughout the world. By far the most important is Paraguay tea (see MATÉ) made from the leaves of *Ilex paraguayensis*; from *Ilex Cassine* (see HOLLY) the North-American Indians used to make a drink called Youpon, and in India Lemon Grass (q.v.) is sometimes used.

Bourbon tea is distilled from the leaves of the *Angræcum fragrans* (see ORCHIDS), and the South African Bushman tea from *Cutha* (q.v.) *edulis*. See also CAJUPUT, LEPTOSPERMUM, SAGE.

Mennell, *Tea: An Historical Sketch* (1926).

Teak (*Tectona grandis*), one of the most valuable timbers known, is the wood of a large deciduous tree (family Verbenaceæ) with leaves from 10 to 20 inches in length, and from 8 to 15 inches in breadth. The tree, which grows best in a dry tropical climate, has small white flowers in panicles. It is found in Central and Southern India, except on the east coast, and there are extensive forests of it in Burma and Siam. It extends also into Java and some neighbouring islands. The annual output at present is about 260,000 tons, of which 225,000 tons come from Burma. In India growing teak is placed under the management of a conservator of forests, and very little is now exported from that country, the demand for the wood being greater than the supply. The wood, highly prized for its great durability, is of a quiet yellow colour, tending to brown, and like many other kinds of timber has a characteristic odour. It is classed as a hardwood, though it is only of medium hardness, taking, however, a good polish; and it is straight grained and strong. Although easily worked when not long cut down, it readily blunts tools after being kept some length of time. Its average specific gravity when dry is about .585. Teak does not shrink much in seasoning, and it is believed to expand and contract less by differences of temperature than most woods. Unless very thoroughly seasoned it has some tendency to split, and this is perhaps its chief defect. It is much less resinous than some other well-known hardwoods, such as mahogany and rosewood, but it is usually said to contain an aromatic essential oil which prevents iron in contact with it from becoming rusted, and for this reason it has been used for the backing to the armour-plates of ships of war. A sticky elastic extract, to some extent resembling india-rubber, is obtained from teak by treating the wood with naphtha or ether. It is probably this which is the real cause of the wood preventing iron from rusting. The pores of the wood are sometimes filled with a white substance, calcium phosphate. There is a high percentage both of this and of silica in the ash of teak, and this no doubt explains why carpenters and other tradesmen consider it gritty. White ants rarely attack the wood if it is sound, but nevertheless logs of it are often badly eaten by the teredo. Teak wood varies considerably in quality even when perfectly sound.

In India teak is used for all kinds of work where strength and durability are required, such as for building ships, houses, and bridges; also for the construction of railway carriages and furniture. In England it is employed in shipbuilding, and to some extent for architectural purposes, such as shop fronts, as well as for furniture. It has numerous minor applications. The leaves of the tree yield a red dye. Being of large size they are used in India for plates and for thatching. The import of teak into Great Britain has decreased very much

during the present century. In 1900 the imports into Great Britain were 63,080 loads, while in 1922 they only amounted to 19,963 loads.

African teak (*Oldfieldia africana*) is imported from the west coast of Africa; it is also a valuable timber, but less so than true teak.

Teal (*Nettion*), a genus of small, widely distributed, fresh-water Ducks, rather silent, and chiefly nocturnal, feeding on water-plants, seeds, insect-larvæ, worms, and the like. The down-lined nest is usually at some distance from water, among herbage or heather; there are eight to ten usually greenish eggs. The Common Teal (*Nettion crecca*),

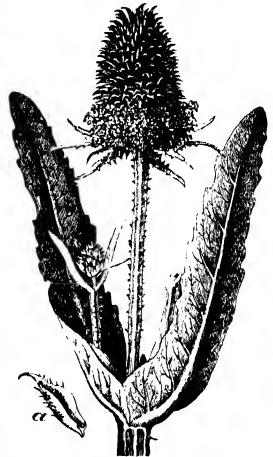

Common Teal (*Nettion crecca*), male and female.

a beautiful bird, breeds abundantly throughout the British Islands and Europe, and ranges from the Azores, over Asia, to Alaska. The affection of the mother for the brood reaches a high level. In America it occurs as a wanderer, the common representative of the genus being the closely allied Green-winged Teal (*Nettion carolinense*), which has occurred twice or thrice in Britain. There are many other species, and nearly allied is the Garganey (*Querquedula ciria*) of local occurrence in Britain.

Tears usually consist of pure water, with saline traces; but in cases of poisoning may show the poison, and in diabetes become saccharine like the other secretions. The lachrymal apparatus is described at EYE. Serving normally to moisten eyeballs, eyelids, and inside of the nose, they are regularly secreted in normal quantities, and disappear by the duct into the nose. Where there is spasmodic contraction of the muscles about the eye, as in fits of coughing, yawning, or immoderate laughter, the tears are squeezed out from the eyelids and run down the cheeks. In man they are also the natural outcome of strong emotion, and are secreted in greatly increased quantity; they much more constantly accompany crises of fear, anxiety, grief, affection, and keen joy than physical pain. Old age is comparatively tearless. Some animals, especially deer, are credited with weeping tears of grief. Darwin says few animals shed tears at all; he failed to notice weeping in monkeys, but records Emerson Tennent's opinion that elephants weep with sorrow, as supported by the keepers of tame elephants. See Darwin's *Expression of the Emotions* (1873).

Teasel (*Dipsacus*), a genus of plants of the family Dipsacaceæ. This family consists of herbaceous and half-shrubby dicotyledons, with opposite or whorled leaves, and flowers in heads or whorls, surrounded by a many-leaved involucre. There are about five genera and 150 species comprised in the family, all natives of the temperate parts of the Old World. In the genus *Dipsacus* the flowers are separated from each other by long, stiff, prickly-pointed bracts. The only valuable species of the family is the

Fuller's Teasel, or Clothier's Teasel (*D. fullonum*), a native of the south of Europe, naturalised in some parts of England. It is a biennial, several feet high, with sessile serrated leaves, the stem and leaves prickly; and with cylindrical heads of pale or white flowers, between which are oblong,

Fuller's Teasel (*Dipsacus fullonum*):
a, a bract.

acuminated, rigid bracts, hooked at the point. The heads are cut off when the plant is in flower, and are used in woollen factories, and by fullers and stocking-makers, for raising the nap on cloth. No mechanical contrivance has yet been found to equal teasel for this purpose, to which the hooked points, the rigidity, and the elasticity of the bracts are admirably adapted. The heads of teasel are fixed on the circumference of a wheel or cylinder, which is made to revolve against the surface of the cloth. Teasel is cultivated in many parts of Europe, and is imported into Britain, but is cultivated to some extent in England, particularly in Somersetshire and Yorkshire. The seed is sown in March, on well-prepared, strong, rich land, and the plants thinned out to a foot apart; in August of the second year the heads are ready to be cut. The flowers of teasel abound in honey, and the seeds are used for feeding poultry. The root was formerly in use as a diuretic and sudorific.

Teb. EL, 50 miles SSE. of Smakin, was the scene, on 29th February 1884, of General Graham's defeat of Osman Digna's forces, that victory being preceded by Baker Pasha's defeat near Tokar (4th February), and succeeded by the second British victory of Tamaniab (13th March).

Technical Education, of such a kind as best to fit the youth of the country for their work in after life, is especially necessary in the case of those on whose work depends the material welfare of the nation—artisans, foremen or employers, farmers or merchants or commercial travellers. The public interest in the subject was aroused by the fact that in 1881, when a Royal Commission was appointed to consider the question, education in Britain was in this respect very much behind that provided in such countries as France, Germany, and the United States of America.

The methods of technical education are necessarily different in different countries. On the Continent the growth of the industrial system has accompanied or rather followed that of the technical schools. These have thus been able to render very great direct assistance to the industries; while even the injurious effect of compulsory military service has been much diminished by the inducement to higher technical study involved in the offer of a shortened period of service to students who have passed successfully through a technical

school. In Britain long-continued industrial supremacy has led to a well-developed industrial organisation in which the old opportunities for the trade education of apprentices in the workshops have largely disappeared, and their place is only now being filled by outside teaching. In Britain, moreover, the difficulty of reorganisation is increased by the power of trade societies, which insist upon the letter of the apprenticeship period although its spirit is gone.

In the earlier stages of education the aims and the conditions are practically the same in all countries. The subjects of instruction and the methods of teaching must be such as will best train the intelligence, the observing and reasoning powers, and pave the way for manual dexterity. In the teaching of arithmetic every opportunity must be taken to connect figures with facts, and pupils must be accustomed to solve the simple problems of price and measurement that are of constant occurrence in daily life. English language and composition is not only valuable as a medium for literary culture, but it is technical in so far as it leads to the accurate description of an object, a process, or an event, or to the full understanding of such a description. Drawing offers a ready means of training the hand and eye; while modelling and the use of tools are valuable aids in this important relation. The accurate study of common things ought to form an essential part of the training of the pupils who have to acquire habits of inquiry; it is also the foundation of that familiarity with properties of materials which is the basis of good work in the industries. It is this study of common things which is known as 'Elementary Science' in school programmes. Throughout the elementary stage of education it is the method as much as the matter that constitutes the claim of the work to be described as technical.

In Britain the higher stages run along two parallel lines—the one for pupils who devote their time to systematic study, and for these the teaching is carried on in day classes; the other for pupils who spend the day in work in a trade workshop, in an office, or in the field, and for whom only the evenings are available for instruction in sciences—in the principles underlying their daily work and in languages. Considering day classes first, we find in every town of considerable size secondary schools adapted to the needs of boys from thirteen to sixteen years of age. In most of these adequate instruction is given in technical and commercial arithmetic, in mathematics, and in modern languages. In many towns there are also technical schools in which the training includes moreover free-hand and mechanical drawing, handicraft, and the branches of science that are likely to be of most advantage to the pupils—applied mechanics, steam, electricity for engineering students; chemistry and agriculture for agricultural students, and so on. The great majority of the pupils attending these schools pass from them directly to work, and continue their education by attendance at advanced evening classes, or by attending advanced day classes for a year or two after completing an apprenticeship. Some, however, give up a year or more, when they are from sixteen to eighteen years of age, entirely to study before taking up practical work. This course is followed mainly in industries such as engineering, mechanical or electrical, chemical or textile manufactures, or agriculture, where the processes involve applications of principles which can be fully understood only by those who have studied a fairly wide range of science. The advanced classes for the instruction of such students are to a large extent of a practical kind; much of the work is done in laboratories. All colleges for such work require fully equipped

chemical, physical, mechanical, and engineering laboratories, workshops for wood and iron, as well as a full complement of appliances for teaching art, the principles of agriculture, or such other departments of applied science as are required by the students in attendance. It is also desirable that the students should have facilities for continuing their language studies and for becoming familiar with book-keeping and commercial practice. After a course of study such as is provided in a technical college of this kind the students are in a position to benefit very readily by the experience they will have in the manufactory or office or on the farm. They will have thoroughly mastered the principles, and have learned something of the modes of their application, so that they enter upon their work with their eyes open alike to the possible causes of failure and to likely avenues of advance.

For the benefit of students who are unable to devote their entire energy to study up to the age of eighteen, or even up to sixteen, evening classes have been established throughout the country in which the work ranges through the standards described here as secondary and advanced. It is thus possible for a lad who leaves school for a trade at the age of thirteen or fourteen to continue his studies by attending evening classes, and he will find that by diligent work for four or five years he may complete the secondary stage of his education, while three or four more will enable him to become familiar with that theoretical knowledge whose applications he has been practising all these years. This prolonged course is required only for those who would fit themselves for any promotion that may be open to them; for the less ambitious a shorter course suffices. For all, however, it is now realised that what is first wanted is a thorough grasp of elementary principles such as will enable a man to make the most of the experience and deftness he acquires in the course of his practical work.

The scope of the technical education required for each of the thousand-and-one occupations of the day is, according to the British view, limited by the accepted conclusion that the best place for a young man to learn the practice of his trade or business is in the workshop or office, as the case may be. But while this is so it is also recognised that there are many matters of general knowledge essential to the due understanding of this practice, many questions of materials, design, principles, and methods which it is nowadays quite impossible for a beginner to be instructed in during business hours, and which can be both more economically and more efficiently taken in hand by an organisation specially charged with such work. A technical school may thus be complete without any teaching of a trade. In fact, in Britain, trade teaching in schools or colleges has been suggested only in the case of a few special industries, and to a certain extent in others for youths in exceptional circumstances.

On the continent of Europe and in America the provision for the technical education of workmen and foremen is not in most respects in advance of that now made in Britain. For masters and managers, however, there have been in active operation for many years numerous technical schools, supported almost entirely by the several states, housed in palatial buildings, equipped with costly and extensive laboratories and museums, and conducted by staffs of professors and teachers so numerous as to admit of the utmost subdivision of the subjects taught. Of the Continental schools, perhaps the best known is that of Charlottenburg, near Berlin.

The evening classes held under the auspices of the old Science and Art Department had done

something in the way of providing technical education in Britain; the system of examinations inaugurated by the City and Guilds of London Institute, and the technical colleges founded by it in the metropolis, had an even more direct and practical bearing on the solution of the problem. In 1889 came help from the legislature. In that year was passed the Technical Instruction Act, which empowered county and borough councils and urban sanitary authorities to levy a rate not exceeding 1d. in the £ to supply, or aid in supplying, technical education within their bounds; and a further stimulus was given to local authorities in the following year by permitting them to use for this purpose the residue of the beer and spirit duties which devolved upon them by the Local Taxation Act. This encouraged, many of the larger authorities undertook the work, and either built and equipped institutes for themselves (e.g. the large and handsome College of Technology at Manchester), or subsidised existing institutions. By the Education Acts of 1902 and 1903 the powers of these Technical Education Committees were transferred to the newly established Local Education Committees, which were made responsible for the supply and co-ordination of elementary, secondary, and technical education within their borders. In 1918 separate Education Acts for England and Scotland provided for the compulsory attendance of young persons (with certain exceptions) upon *day* continuation classes until they reached 18 years of age, thus greatly extending their opportunities for studies 'conducive to their efficiency in the employment in which they are engaged'; these powers, however, have been held in abeyance. Technical education of an advanced character is also provided in connection with most of the younger universities, such as those at Manchester, Liverpool, Birmingham, Leeds, Sheffield, &c., and at such institutions as the Imperial College of Science and Technology, London (arising from the fusion of the Central Technical College of the City and Guilds, the Royal College of Science, and the Royal School of Mines), the Royal Technical College, Glasgow, the Heriot-Watt College, Edinburgh, and the various Polytechnic Institutes in the metropolis.

As the outcome of the *Agriculture and Technical Instruction (Ireland) Act of 1899*, technical education in Ireland was administered by the specially constituted Department of Agriculture and Technical Education, but is now under the supervision of the governments of the Irish Free State and of Northern Ireland, the large and important Municipal College of Technology in Belfast being the most recent development; in Scotland, the work is carried on by the Local Education Authorities, by the universities, and in such institutions as those already alluded to.

See the Reports of the Commission above cited; the Reports of the U.S. Commissioner of Education, the *Proceedings of the International Conference (1884)*; the prospectuses of the several technical schools; Rutler, *Education in the United States (1900)*; Paulsen, *German Education* (with bibliography, 1908); Sir Philip Magnus, *Educational Aims and Efforts (1910)*; Board of Education, *Special Reports on Educational Subjects*; Reports of the Association of Technical Institutions and of the Association of Teachers in Technical Institutions; also the articles POLYTECHNIC, EDUCATION, ART (INSTRUCTION), SLOVOD.

Technology, the systematic knowledge of the industrial arts, represented by innumerable articles in this work, such as those on spinning, weaving, calico-printing; the manufactures of cotton, woollen goods, silk; the production of the several metals, gas, sulphuric acid, bread, beer, wine, &c.

Teck, an ancient principality named from a castle on 'the Teck,' a limestone peak in the Swabian Alb, 20 miles SE. of Stuttgart. Held by various families from the 11th century on, it passed in 1498 to the Dukes of Württemberg. In 1863 the king of Württemberg conferred the principality on Duke Albert of Württemberg's son (1837-1800), who in 1866 married the Princess Mary of Cambridge. Their daughter, Princess Mary, became Queen of the United Kingdom in 1910, while their youngest son, the Earl of Athlone, became Governor-general of South Africa in 1924. In 1917 the name of the house was changed to Cambridge. See L. Felberman, *The House of Teck* (1911).

Tecumseh (or *Tecumtha*; 1768-1813), chief of the Shawnees (q.v.), who headed the rising suppressed by Harrison in 1811, and passing into the English service, commanded the Indian allies in the war of 1812-13 with the rank of brigadier general. He was killed fighting bravely at the Thames in Canada. See Lives by Eggleston (1878), and Raymond (1915).

Teddington, a town of Middlesex, on the left bank of the Thames, 13½ miles SW. of London. Adjoining is Bushy Park, with the National Physical Laboratory (1902). Pop. 21,200.

Te Deum, a majestic Latin hymn of the Western Church, so called from its first words. By an unsupported tradition it is ascribed to St Ambrose and St Augustine, and often called the Ambrosian Hymn; and by another to Hilary of Arles. The first actual reference to it is in the rule of Caesarius, bishop of Arles in 502-540; it was certainly extant in the 5th century, and in its modern form was used by Hincmar of Rheims in the 9th century. The hymn in its current form consists of twenty-nine verses; the first twenty-one verses are uniform in the four oldest versions current, and it seems probable that verses 1-10 were a Greek hymn dating back to the 2d century. In the Anglican morning prayer it follows the first Lesson, except when the Benedicite is preferred as its alternative. It is frequently used also in the services of both Presbyterian and Congregationalist churches, and there are more than twenty metrical renderings of it in English hymnology.

See the Rev. John Julian's *Dictionary of Hymnology* (1892), and Prebendary Edgar C. S. Gibson in *Church Quarterly Review* for April 1884.

Tees, a river in the north of England, rising on Cross Fell, Cumberland, and flowing 70 miles eastward, mainly along the boundary between Durham and Yorkshire, till it falls into the North Sea, 4 miles below Stockton. Owing to works carried out since 1853 it is now navigable to that town for vessels of large burden, those works including the construction of two breakwaters at the mouth.

Teeth, hard bodies in the mouth, attached to the skeleton, but not forming part of it, and developed from the dermis or true skin. 'They present,' says Owen, 'many varieties as to number, size, form, structure, position, and mode of attachment, but are principally adapted for seizing, tearing, dividing, pounding, or grinding the food. In some species they are modified to serve as formidable weapons of offence and defence; in others, as aids in locomotion, means of anchorage, instruments for uprooting or cutting down trees, or for transport and working of building materials. They are characteristic of age and sex; and in man they have secondary relations, subservient to beauty and to speech. Teeth are always intimately related to the food and habits of the animal, and are therefore highly interesting to the physiologist; they form, for the same reason, important guides to the naturalist in the classification of animals.'

True teeth consist of one, two, or more tissues, differing in their chemical composition and in their microscopical appearances. 'Dentine,' which forms the body of the tooth, and 'cement,' which forms its outer crust, are always present; the third tissue, the 'enamel,' when present, being situated between the dentine and cement. The *dentine*, which is divided by Owen into hard or true dentine, vaso-dentine, and osteo-dentine, consists of an organised animal basis, disposed in the form of extremely minute tubes and cells, and of earthy particles.

Fig. 1.—Vertical Section through a Tooth lodged in its socket:

a, enamel; b, dentine; c, enamel prisms, or cement; d, lining of the cavity in the gum; e, bony socket in gum; f, pulp cavity.

The tubes and cells contain, besides the calcareous particles, a colourless fluid, which is probably transuded blood plasma, or *liquor sanguinis*, and contributes to the nutrition of the dentine. In hard or true dentine the *dental tubes* proceed from the hollow of the tooth known as the *pulp cavity*, in a slightly wavy course, nearly at right angles to the outer surface. 'The hard substance of the tooth is thus arranged in hollow columns, perpendicular to the plane of pressure, and a certain elasticity results from these curves; they are upright where the grinding surface of the crown receives the appulse of the opposing tooth, and are horizontal where they have to resist the pressure of contiguous teeth.

The tubuli also receive the plasma transuded from the remains of the vascular pulp, which circulates by anastomosing branches of the tubuli through the dentine, maintaining a sufficient though languid vitality of the system. The delicate nerve-branches on the pulp's surface convey sensations of impressions affecting the dentine—sensations of which every one has experienced the acuteness when decay has affected the dentine, or when mechanical or chemical stimuli have "set the tooth on edge." When a part of the primitive vascular pulp from which the dentine is developed remains permanently uncalcified, red blood is carried by 'vascular canals' into the substance of the tissue. Such dentine is called *vaso-dentine*, and is often combined with true dentine in the same tooth, as, for example, in the large incisors of certain rodents, the tusks of the elephant, and the molars of the extinct megatherium. When the cellular basis is arranged in concentric layers around the vascular canals, and contains 'radiated cells,' like those of bone, this is termed *osteo-dentine*, and resembles true bone very closely. The *cement* always corresponds in texture with the osseous tissue of the same animal, and wherever it occurs in sufficient thickness, as on the teeth of the horse or ox, it is traversed like bone by vascular canals. Moreover, when the osseous tissue contains minute radiated cells, precisely similar cells are likewise present in the canals, and constitute its most marked characteristic. The relative densities of dentine and cement vary according to the amount of earthy matter. In the complex grinders of the elephant and some other animals the cement, which forms nearly half the mass of the tooth, wears down sooner than the dentine. The *enamel* is the hardest of all the animal tissues, and contains no less than 96.4 per cent. of earthy matter

(mainly phosphate of lime), while dentine contains only 72 per cent., and cement and ordinary bone only 69 per cent. of earthy matter.

In a few fishes the teeth consist of a single tissue—a very hard kind of non-vascular dentine. Teeth consisting of dentine and vaso-dentine are very common in fishes. Dentine and cement constitute the grinding teeth of the dugong. In the teeth of the sloth the hard dentine is reduced to a thin layer. 'The human teeth and those of the carnivorous mammals appear at first sight to be composed of dentine and enamel only; but their crowns are originally, and their fangs are always covered by a thin coat of cement. There is also commonly a small central tract of osteo-dentine in old teeth. The teeth called compound or complex in mammalia differ as regards their composition from the preceding only by the different proportion and disposition of the constituent tissues. Fig. 2 is a longitudinal section of the incisor of a horse; *d* is the dentine, *e* the enamel, and *c* the cement, a layer of which is reflected into the deep central depression of the crown; *s* indicates the coloured mass of tartar and particles of food which fills up the cavity, forming the "mark" of the horse-dealer.' Far more complex forms of teeth than this may be produced by peculiar arrangements, chiefly inflections, of the tissues (see LABYRINTHODONTS). Another kind of complication is produced by an aggregation of many simple teeth into a single mass, as in some fishes and a few mammals. The teeth of the Aard-vark (q.v.) are of this kind, each tooth being composed of a congeries of long and slender prismatic denticles of dentine, which are cemented together. In the elephant the compound molars belong to this class, the denticles being in the form of plates vertical to the grinding surface, and transverse to the long diameter of the tooth.

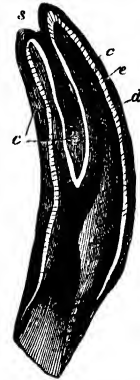

Fig. 2.—Longitudinal Section of the Incisor of a Horse.

The teeth of *fishes*, in regard to their number, form, substance, structure, situation, or mode of attachment, offer a greater and more striking series of varieties than do those of any other class of animals. In all fishes the teeth are shed and renewed, not once only, as in mammals, but frequently during the whole course of their lives. Tortoises and turtles, toads, and certain extinct Saurians are toothless. Frogs have teeth in the upper, but not in the lower jaw. Newts and salamanders have teeth in both jaws and upon the palate; and teeth are found on the palate as well as on the jaws of most serpents. In reptiles, as a general rule, the base of the tooth is anchored to the bone which supports it. The completion of a tooth is soon followed by preparation for its removal and succession, the faculty of developing new tooth-germs being apparently unlimited in this class. The extinct Odontornithes (q.v.) are the only birds with teeth. Of mammals there are a few genera and species devoid of teeth. The true ant-eaters, the pangolins, and the echidna are strictly toothless. The ornithorhynchus has horny teeth, and the whales have transitory teeth, succeeded in the upper jaw by whalebone. The Narwhal (q.v.) has a peculiar development. The elephant has never more than one entire molar, or parts of two, in use on each side of the upper and lower jaws; to which are added two tusks, which are modified

incisors, more or less developed, in the upper jaw. The bear's tusks are large and powerful canines. Some rodents have two grinders on each side of both jaws, which, added to the four cutting-teeth in front, make twelve in all; but the common number of teeth in this order is twenty, although hares and rabbits have twenty-eight each. The number of teeth, thirty-two, which characterises man, the apes of the old world, and the true ruminants, is the average one of the mammals. The dentition is often summarised as to the number and position of incisors, canines, molars, and premolars, thus: the *dental formula* of the typical mammal is *inc.* $\frac{2}{2}$, *can.* $\frac{1}{1}$, *pm.* $\frac{1}{1}$, *m.* $\frac{3}{3}$ = 44; or more briefly $\frac{2}{2} \frac{1}{1} \frac{1}{1} \frac{3}{3}$. The absent teeth may be denoted by 0 or by a blank. The dentition is indicated in the articles on the several animals where it is of interest (especially at HORSE), and in the articles on the great groups of animals (see, for example, CARNIVORA). It is only in the mammals that we have a well-marked division of the teeth into the four kinds of incisors, canines, premolars, and molars, each of which claims a brief description.

The *incisors*, or cutting-teeth, are situated in front, and possess a single conical root or fang, and a vertical crown bevelled behind, so as to terminate in a sharp cutting edge. These teeth are specially fitted, as their name implies, for cutting the food. In man there are two of these incisors in each side of each jaw (in the pre-maxilla). The permanent incisors, molars, and premolars are preceded by a set of deciduous or *milk* teeth, which are lost before maturity, and replaced by the permanent ones. In herbivorous animals they crop the herbage; in rodents (the rabbit, hare, rat, beaver, &c.) these teeth are very much developed, and differ from any other teeth occurring in mammals in this respect, that their growth continues throughout life; and if their length does not constantly increase, it is because their free extremity or edge

The *premolars* (known also as *bicusps* and *false molars*) come next in order to the canines; they are smaller than the latter, and their crown presents two pyramidal eminences. In man there are two premolars in each half-jaw. Their function more nearly approaches to that of the true molars behind them than to that of the canines.

The *true molars* (or *multicusps*) are placed most posteriorly. They are remarkable for their comparatively great size, the square form of the upper surface, on which are from three to five elevations or cusps, and for roots, which may number from 2 to 5. They appear first in the permanent set. In man there are three molars in each half-jaw, which are specially employed for grinding the food under the action of the muscles of the lower jaw. The posterior one is termed the *wisdom tooth*, from its being cut the latest.

The teeth are so admirably adapted for the special purposes which they are called upon to fulfil that it is generally easy, from a careful examination of them, to say to what class of animals they belong, and to draw various conclusions regarding the habits and structure of the class generally. Thus, in carnivorous animals the molars are not grinding-teeth, but present sharp cutting edges, and those of the upper and lower jaw overlap each other, resembling a pair of scissors in their action. In insectivorous animals the molars have a tuberculated surface, with conical points and depressions, so arranged as to lock into each other. In frugivorous animals, living on soft fruits, these teeth are provided with rounded tubercles, while in herbivorous animals they have a broad, rough surface, resembling a millstone.

There is also a close connection between the articulation or joint of the lower jaw and the nature of the food used by the animal. Thus, in purely carnivorous animals, in which the teeth simply tear and cut the food, no grinding motion is required, and the jaw is capable only of a simple hinge-motion in the vertical plane; while in herbivorous animals the joint is so constructed as to allow of extensive sliding and lateral motion of the lower molar teeth upon the upper. In man both the form of this articulation and the general character of the teeth point to an intermediate position in relation to food, and form a physiological argument for the mixed diet which general custom has decided to be most natural to our species.

See the articles CARNIVORA, DOG, RODENTIA, SKULL, for illustrations of teeth *in situ*; and besides general works on anatomy, human and comparative, Owen's *Odontography* (1845) and other works, and Flower's *Osteology of the Mammalia* (1886).

DISEASES OF THE TEETH.—Decay (*Caries*) is by far the most common of the diseases which affect the teeth, and consists in a gradual and progressive disintegration of the tooth-substance. Among the chief predisposing causes are hereditary defects of quality; imperfect calcification; pits and grooves in the enamel; overcrowding of the teeth, facilitating the retention of particles of food between them; constitutional disorders, chiefly those affecting the digestive organs; and debilitating causes generally. The exciting cause of caries has been proved by Professor Miller of Berlin to be due to the action of micro-organisms. According to him, 'the first stage of dental caries consists in the decalcification of the tissues of the teeth by acids which are for the greater part generated in the mouth by fermentation,' the agents concerned in the process being micro-organisms and the acid they produce—lactic acid.

Decay is rarely met with on smooth surfaces exposed to the friction of food and the direct washings of the saliva. It usually begins in some pit or groove in the enamel or between the teeth.

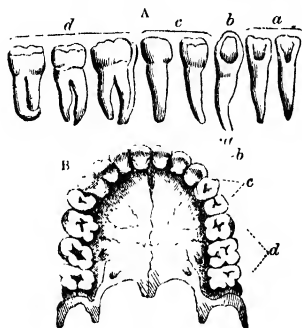

Fig. 3.

A, the separate human teeth as they occur in the half-jaw of the adult; B, the human teeth *in situ* in the upper jaw; a, a, incisors; b, b, canines; c, c, premolars; d, d, true molars.

is worn down by attrition as fast as they grow at the base from their roots.

The *canines* (so called from their prominence in the dog) come next to the incisors. Their crown is rather conical than wedge-shaped, and their fang sinks more deeply into the jaw than in the case of the incisors. In all carnivorous animals they are largely developed, being obviously formed for tearing the flesh of their prey. In man there is one canine tooth in each half-jaw; and there is never more than this number in any of the lower animals.

such points forming a lodgment for the development of the organisms. Once the enamel has been penetrated the decay proceeds more rapidly, spreading laterally beneath the as yet healthy enamel and towards the pulp. The more dense the structure of the tooth the more directly does the decay penetrate in the direction of the pulp, although its progress is not so rapid and its tendency to spread is less. Caries is most common in early life, by far the greater number of cavities making their appearance between the ages of six and eighteen. Its colour varies from pale brown to black, and generally the lighter the colour the more rapid is the decay. Pain may be felt soon after the enamel has been penetrated, or may be delayed until the nerve (pulp) has become almost or quite exposed; yet, strangely enough, it is sometimes altogether absent, particularly in very hard teeth. When the pulp has become nearly encroached upon, the patient's sensations will warn him against taking hot or cold, sweet or acid fluids. Ultimately the pulp becomes exposed, when the pain increases and may become very violent, especially if the nerve be pressed upon by food forced into the cavity by mastication. Should this take place the pulp becomes acutely inflamed and soon dies, when the pain may either cease or go on till an alveolar abscess is formed. The treatment of caries can only be undertaken by the dentist, and varies with the extent and character of the disease. See DENTISTRY.

Periostitis and Alveolar Abscess.—Periostitis is an inflammation of the membrane (periosteum) which covers the roots of the teeth and lines their sockets. It may be either general or local. When general the majority or all of the teeth are commonly involved. Periostitis of this type is usually due to constitutional causes (such as rheumatism), or the effects of some such agent in the system as mercury, or the presence of accumulated tartar about the necks of the teeth. When the disease is local—confined to one or two teeth—it may result from a blow or some such injury, or it may proceed from an inflamed pulp; but by far the most common cause is the presence of a dead nerve, the poisonous products of which are liable at any time to cause violent inflammation at the end of the root. Yet it is not uncommon to find that teeth whose pulp dies and whose substance gradually breaks down and decays away do not give rise to any trouble. When acute periostitis has fairly set in, it and its usual accompaniment, alveolar abscess, are perhaps the most painful affections to which the teeth are subject. The symptoms vary in intensity, though the characters remain the same. A dull aching pain is felt, and is relieved at first by pressure upon the affected tooth; as the inflammation increases in severity the tooth rises slightly in its socket, and becomes exquisitely painful when bitten upon; the gum around it becomes congested, and the throbbing pain is almost continuous.

Alveolar Abscess may be defined as a suppurating around the root or roots of a tooth. It is of two varieties, *acute* and *chronic*. Its causes are those of periostitis, which precedes it, the continuous and throbbing nature of the pain indicating the formation of matter (pus) within the surrounding bone. The face, with the glands about the neck, swell, and the glands exhibit tenderness on touch. The pent-up pus forces its way through the bone to reach the surface of the gum at the point of least resistance, which is most often opposite the end of the root or roots (this is popularly known as a 'gum-boil'). It occasionally finds its way along the side of the root, and discharges at the edge of the gum. Sometimes the discharge burrows downwards to find an exit on the face. This is almost peculiar to the lower teeth, and calls for removal of the

tooth affected. With the escape of pus by 'gum-boil' there is a marked abatement in the intensity of the pain, which generally disappears in a few hours and the swelling in a few days. If left to itself, however, the abscess soon assumes the chronic form, the tooth becoming almost if not quite comfortable. This condition may continue for an indefinite period, but there may also be a recurrence of the symptoms in a milder form. Not infrequently chronic abscesses occur without giving rise to any pain, the only evidence of their existence often being a small fistulous opening on the surface of the gum, from which from time to time pus discharges. Even this last may be wanting. If the abscess resist all treatment, the disease can be cut short by the extraction of the tooth, although many cases can be successfully treated and the tooth rendered permanently useful.

Exostosis is characterised by an increase in the thickness of the cementum, the external of the two hard tissues forming the roots of the teeth. Its forms vary from a small nodule or patch to a quantity sufficient to invest the entire root or roots of the same or adjoining teeth. It is most often caused by slight but continued irritation of the pericementum, or by rapid wearing of the masticating surfaces. Occurring as it sometimes does in teeth otherwise sound, its diagnosis is difficult; its presence may not be suspected till an attempt is made to extract the tooth, which, owing to the enlargement of the fangs, cannot even when loosened be removed without great difficulty. Exostosis may often cause neuralgic pains about the jaws.

Impaction and difficult Eruption of the Wisdom and other Teeth.—It is not uncommon to find certain of the temporary teeth firmly set in the adult jaw, and occupying the place of the permanent ones. In such cases the permanent tooth is usually present in the body of the jaw, but it has been retarded in eruption by being too deeply imbedded in the bone. Impaction may also be due to an abnormal direction of growth. Such teeth may appear late in life after all the others are lost, and the bone overlying them has been absorbed and so exposed them. When these cases do occur they are a terrible source for the popular but incorrect idea of a third set of teeth. An impacted tooth seldom gives rise to any trouble, unless it be an upper or lower wisdom, particularly the latter. The cutting of these teeth is sometimes accompanied by distressing symptoms which may be protracted for months or years, unless they are removed by extraction of the tooth. This condition is usually due to imperfect development of the jaw. The tooth usually takes its natural vertical direction, but, being wedged in between the tooth in front and the ascending portion of the jaw behind, only a small portion of the crown is visible. The overlying gum is apt to be bruised by the occlusion of the opposing tooth in the upper jaw; inflammation is thereupon set up, and being maintained by biting may extend to the surrounding parts. Swallowing becomes painful and the motion of the jaws restricted. When it is evident that there is insufficient accommodation in the jaw for the erupting tooth it should be removed.

Inflammation of the Gums, although not a disease of the teeth proper, is one of the most common causes of their premature loss. It may arise from constitutional causes—chronic dyspepsia, rheumatism or gout—or from the administration of such drugs as mercury or iodide of potassium. Most often, however, it results from the presence of tartar about the necks of the teeth, and lack of thorough cleansing. When due to constitutional causes, their appropriate remedies are called for; but when due to the presence of tartar, this deposit

should be carefully removed. See DENTISTRY (*Scaling*).

Absorption of the Alveoli.—The gradual wasting of the bone which surrounds and supports the roots of the teeth, accompanied by a simultaneous recession of the gums, is one of the changes which mark the approach of old age. This wasting may, however, occur in middle life without any visible cause, although the majority of such cases are due to chronic inflammation of the gums, with or without the deposition of tartar. Heredity, or the use of too hard a tooth-brush, may likewise be accountable. The teeth most affected are the front ones; but the reverse of this is not unusual. The gums, especially in front, gradually recede and lay bare the roots; the teeth now become loosened and finally drop out. The treatment consists in the removal of any obvious source of irritation.

Abrasion of the Teeth is a gradual loss of their substance from causes which are purely mechanical. The more common cause is a faulty occlusion of the jaws, but it is also produced by the improper use of the tooth-brush. When the result of mal-occlusion, it shows itself upon the grinding surfaces of the back teeth and the cutting edges of the incisors, which may become rapidly worn down almost to the gum, the rate of progress being frequently hastened by the common habit of grinding the teeth together. When caused by improper brushing it is seen on the front surfaces.

Diseases of the Antrum, while springing from other sources, are often caused by diseased teeth. The cavity in the bone of the upper jaw, known as the Antrum of Highmore, communicates by a small opening with the nose, and is sometimes the seat of inflammation set up by the presence of an abscess in connection with one of the back teeth, the roots of which project into it. The most common symptom of such a condition is an offensive discharge from the nostril of the affected side, increased in quantity when the patient lies down. The treatment is very tedious, much depending upon the age and general health of the patient; it consists in the removal of any diseased teeth from the affected side. This extraction may be followed by a discharge of pus; if not, an opening into the antrum should be made through the socket of one of the roots, and the cavity drained, suitable stimulating and disinfecting lotions being injected by means of a syringe till a healthy condition is established. Among the less common forms of disease which attack the teeth and gums are necrosis, dentigerous cysts, odontomes, epuloid and polypoid and other tumours of the jaws, and diseases of the tooth-pulp itself. These, however, are so comparatively rare as to be of no interest to the general reader.

The use of X-rays as an aid to diagnosis is one of the greatest advances in modern dentistry. Thus in a child the number and position of the permanent teeth can be determined before they are cut, and the treatment of irregularities of the teeth made much more certain. So, too, many diseased conditions can be recognised, such as caries, exostosis, absorption, abscesses, the extent to which pyorrhea has developed, cysts, impacted teeth, and fractured and decayed roots that may be buried under the gums.

Toothache is not so much a disease as a symptom. Its chief causes are mentioned under *Caries* and *Alveolar Abscess*. The pain, which varies greatly in degree, character, and duration, depends largely upon its cause, and the health of the patient at the time of the attack. Only a transient uneasiness may in some instances be felt, and, as often, in others almost insupportable agony. If neuralgic in character it most frequently occurs in paroxysms at more or less regular inter-

vals. When toothache is due to caries with or without simple exposure of the pulp, the attack is brought on by taking hot or cold, sweet or acid fluids, and is seldom of long duration. To afford relief in such cases as these, gently wash out the cavity with a solution of carbonate of soda; then, drying it carefully with a piece of cotton-wool, take a very small pellet of wool dipped in eucalyptus oil and place it in the bottom of the cavity; or over this place a piece of cotton-wool large enough to fill the cavity and saturated with the following solution: 1 drachm of mastic in 1½ ounce of Eau de Cologne. This should be changed daily. When the pain is caused by the forming of an alveolar abscess the tooth will be found insensitive to change of temperature but very susceptible to pressure. The patient now becomes feverish, and the pain, which is at first of a dull heavy character, becomes more intense, throbbing, and continuous, till pus has been formed and discharged through the gum. Provided the tooth is likely to prove useful and the patient cannot consult a dentist, the gum should be carefully painted with tincture of iodine, or the old-fashioned plan of placing a roasted fig over the root may be resorted to; at the same time it is well to give an aperient such as Epsom salts, followed by a full dose of quinine—6 to 8 grains for an adult. Great relief follows this treatment, which is, of course, only temporary. If an abscess shows signs of pointing upon the gums it may with advantage be lanced. Poulices *must never* be applied to the face, for heat tends to draw the pus outwards. Abscesses in connection with the lower wisdoms often assume a very serious character unless cut short by extraction of the tooth.

Hygienic Care of the Teeth.—Many of the diseases of the teeth and gums might be prevented or greatly retarded by proper attention to the cleansing of these organs. The implements best fitted for this purpose comprise the quill toothpick, waxed silk thread and brushes, with suitable powders. The toothpick ought to be used after every meal, but it should be supplemented by the use, between the teeth, of floss silk, which will remove deposits accumulating where contiguous teeth touch. The brush is used to remove all deposits solid and mucous, and it gives the teeth a bright and polished appearance, especially if a good tooth-paste or powder is used at the same time. The mechanical friction also stimulates the gums to more healthful action. The teeth should be brushed twice daily, in the morning and in the evening. The manner of using the brush is more important than many people suppose. The general method is to brush horizontally, but a moment's reflection will show that this leaves untouched the very situations most in need of cleansing. The brush, used properly, should be pressed against the teeth and the handle rotated so as to make the bristles sweep vertically between and over them: this, coupled with an up-and-down motion, will thoroughly cleanse the interspaces; the inner surfaces of the back teeth are best cleaned in a like manner, while the corresponding parts of the upper and lower incisors are effectually reached by a vertical drawing movement. The brush should be of medium texture, and the bristles of unequal length, and not too closely placed. Over-brushing must be guarded against as carefully as under-brushing, lest the gums and the necks of the teeth be injured. During an illness these precautions are doubly necessary, as the corrosive effects of many medicines are then added to the evil results of a weakened vitality. The use of a glass tube in taking medicines that contain mineral acids and iron is usually supposed to be a sufficient precaution against the action of such

drugs upon the teeth, but this is quite erroneous; the only sure preventive being a weak solution of ordinary baking soda, with which the mouth should be rinsed after every dose. The choice of a tooth-powder should be left to the dentist, for many dentifrices which, no doubt, whiten the teeth do so by the action of some agent which is as deadly to the tooth-substance as to the impurities it is meant to remove. Charcoal (so much used) is quite unsuitable because of its gritty nature. As far as the ordinary individual is concerned, the use of brush and toothpick is the limit up to which one can take care of one's own teeth, so that a thorough examination of the mouth once or twice a year by a trustworthy professional man is necessary to check the diseases of the teeth before they have gone so far as to be irreparable. Especially should this be attended to in children. It is almost impossible to overrate the importance of following, at least in the main if not in detail, the hints given above, for when we consider that the teeth are placed at the very gateway of life, it is not surprising that their neglect should be answerable for many of the disorders of the system. And surely precaution is better than cure.

For a more detailed description of the diseases of the teeth, see the works of Tomes and Colyer.

Teething, the acquirement of teeth, especially of their first teeth, by children from about their seventh month onwards, may take place in strong children without any constitutional disturbance or ailment other than some local irritation or inflammation; many of the infantile diseases once credited to teething are really due to improper feeding (see INFANTS, FEEDING OF) and neglect of hygiene. But the time of teething is more or less a critical period, especially for the nervous system of the child, and is apt to be associated, especially in sensitive children or such as suffer from rickets, with restlessness, disturbed sleep, and even in some cases with Convulsions (q.v.), diarrhoea, and eruptions. Close attention to the general health is always necessary.

Teetotalism. See TEMPERANCE.

Tegern-See, a beautiful mountain lake, 3½ miles long, in the extreme south of Bavaria, 30 miles SE. of Munich; it is a much esteemed summer-resort.

Tegethoff, WILHELM, BARON VON, Austrian admiral (1827-71). See TACTICS.

Tegnér, ESAIAS, one of the most prominent of Swedish poets, was born at Kyrkerud, in the province of Vermland, on 13th November 1782, the son of a country pastor of peasant descent. The boy lost his father when only ten years of age, and owed his education as well as his support to the good-will of kind patrons. At seventeen he enrolled himself a student at Lund University, and graduated, as first student of his year, in 1802; a few months later he was appointed a lecturer in the faculty of philosophy. It was not until 1808 that he attracted any attention as a poet; but the stirring *War-song for the Militia of Scania* made his name known, and the patriotic appeal, *Svea* (1811), made it famous. In the following year he was chosen professor of Greek. The best creations of his poetic genius all belong to a comparatively short period of time (1817-25)—*Song to the Sun* (1817), *Epilogue on the Degree Day at Lund* (1820), *The Candidate for Confirmation* (1820), *Azel* (1821), and *Frithiof's Saga* (1825). After this he only wrote occasional pieces and a couple of incomplete poems of a more ambitious cast. In 1824, however, he had been called to undertake the onerous duties of the bishopric of Vexjö, and to those

duties he gave his strength, until symptoms of mental disease showed themselves (1840); he died 2d November 1846 (see SWEDEN). His work is distinguished by much of the transparent clearness, tranquil ease, and artistic finish that he admired so greatly in the ancient Greeks. At the same time he writes with the warm enthusiasm, the quick poetic feeling, the freshness and vigour of a modern over whom the inspirations of romanticism had passed. And, what has contributed not the least to make him a favourite, his verse is full of melody, rich in imagery, and moves with stately grace and dignity. *Frithiof's Saga*, a cycle of epics treating of old Scandinavian days, is his masterpiece; and notwithstanding certain obvious faults, it is a noble production, one of the most popular poems in Swedish, and a welcome addition to the translated poetry of every literature in Europe. *Azel*, a romance in verse of the time of Charles XII., is more unequal in execution; the other three poems mentioned rank higher than *Azel* in technique, but do not surpass its best passages in poetic insight and inspiration. Tegnér's collected works were published in 1847-50 (7 vols. Stockholm), and again in 1882-85 (8 vols.). The best life is that by his son-in-law, Böttiger, prefixed to the first edition of his collected works. See also monographs by Georg Brandes (1878), Kippenberg (1884), Christensen (1890), and Erdmann (1896). There are many translations. A selection of the best appeared in 1915 with an introduction by P. R. Lieder.

Tegucigalpa, the capital of Honduras, is situated in a fertile valley 3200 feet above the sea, on the river Choluteca, with mountains rising round about. The town has fine parks and buildings, and gold, silver, and mica are mined. Pop. 40,000.

Téhâma. See ARABIA.

Teheran, or TEHRAN, capital of Persia, 70 miles S. of the shore of the Caspian Sea. It stands on a wide plain, dotted here and there with mud-built villages, and pierced with many circular pits, which reach down to the great subterranean watercourses, on which, in this region, the life of animal and plant is altogether dependent. To the north runs in a general east and west direction the lofty range of the Elburz Mountains, rising in Demavend to the height of nearly 20,000 feet above sea-level. The old wall and ditch (4 miles long) were levelled in 1868, and the space thus gained made into a much needed circular road or boulevard. Fortifications, consisting of a bastioned rampart and ditch, were at the same time commenced on a much more extended scale. This enceinte, with its twelve gates and enclosing an area about 10 miles in circumference, was completed in 1873. The town rapidly extended beyond its old limits, more especially on the north side, where many fine streets, gardens, and buildings soon made their appearance, including several government buildings and those of the British Legation. The Shah's palace, entirely reconstructed since 1866, occupies the Citadel, and is both spacious and cheerful, its large courtyards being laid out with gardens and numerous fountains. Besides his town palace, the Shah has several others in the immediate neighbourhood, which he occupies at different seasons of the year. The foreign legations and rich natives are also in the habit of resorting in summer to the cool slopes at the foot of the Elburz, where many of them have commodious houses and fine gardens. Teheran is the commercial centre of Persia, although its manufactures are of little importance. The bazaars, some of which are very handsome structures, are filled with every kind of native and foreign mer-

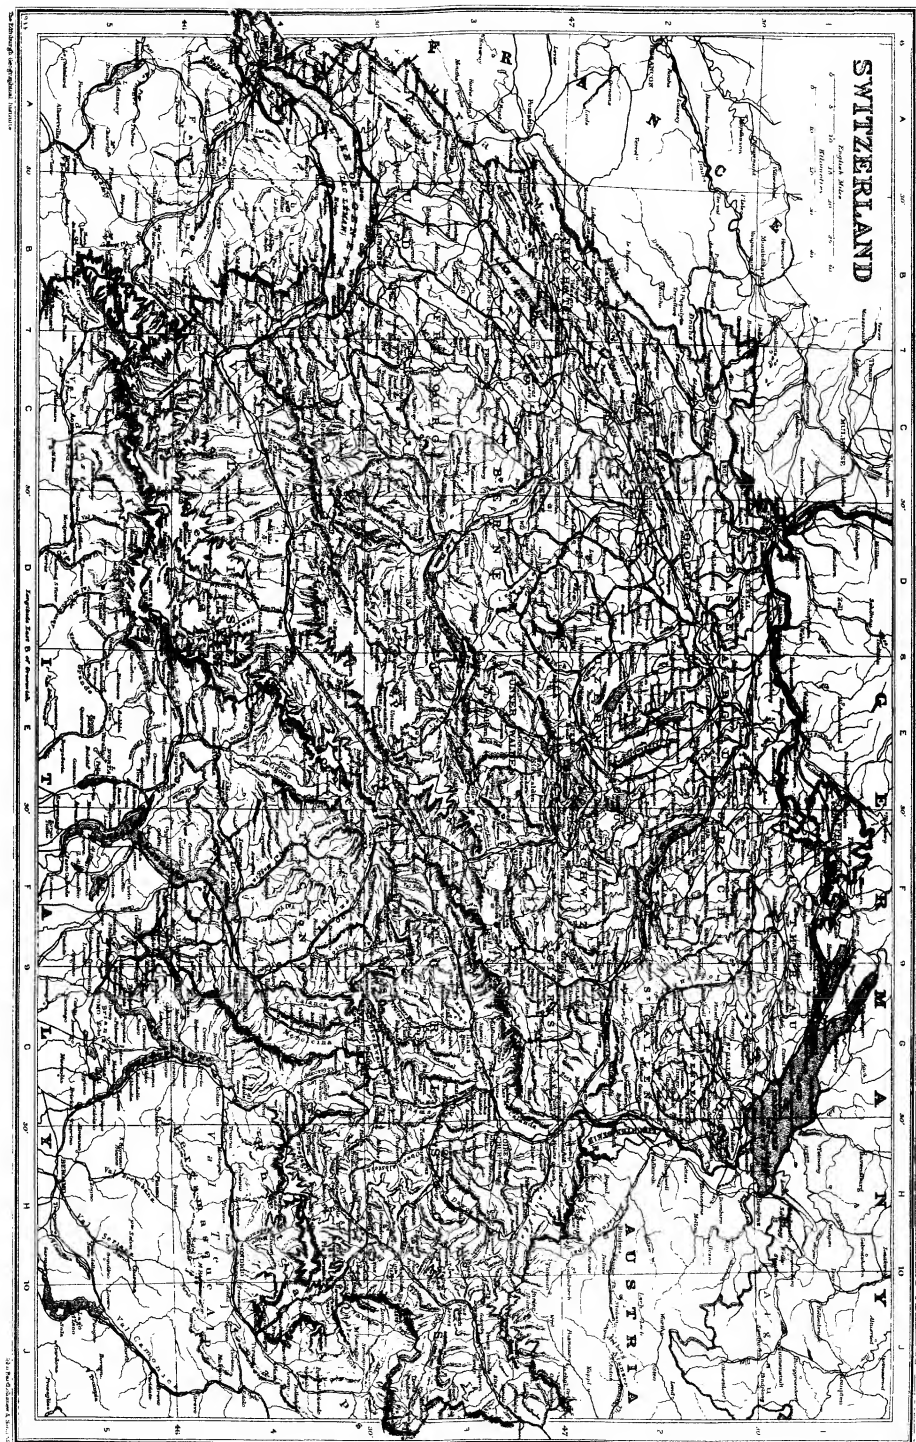

chandise. From Teheran lines of telegraph radiate in almost every direction to the extremities of the kingdom, by far the most important being the lines of the Indo-European Telegraph Department and those of the Central Persia Telegraphs. In 1886 a short line of railway was constructed from Teheran to Shah Abdul Azim, a shrine and place of pilgrimage about 6 miles to the southward of the town. Tramways were also laid down in different parts of the city; and gas and electric lighting have been introduced. The population is about 350,000. In the vicinity of Teheran are the ruins of Rci, the *Rhages* of the Book of Tobit, known in the time of Alexander the Great under the name of *Ragen* and the birthplace of Harûn-al-Raschid. See PERSIA, and works there cited.

Tehuantepec, a picturesque town of Oaxaca, Mexico, 10 miles above the mouth of the river Tehuantepec, with 10,000 inhabitants (mostly Indians) within its municipality. The isthmus on which it stands is only 120 miles wide, and a

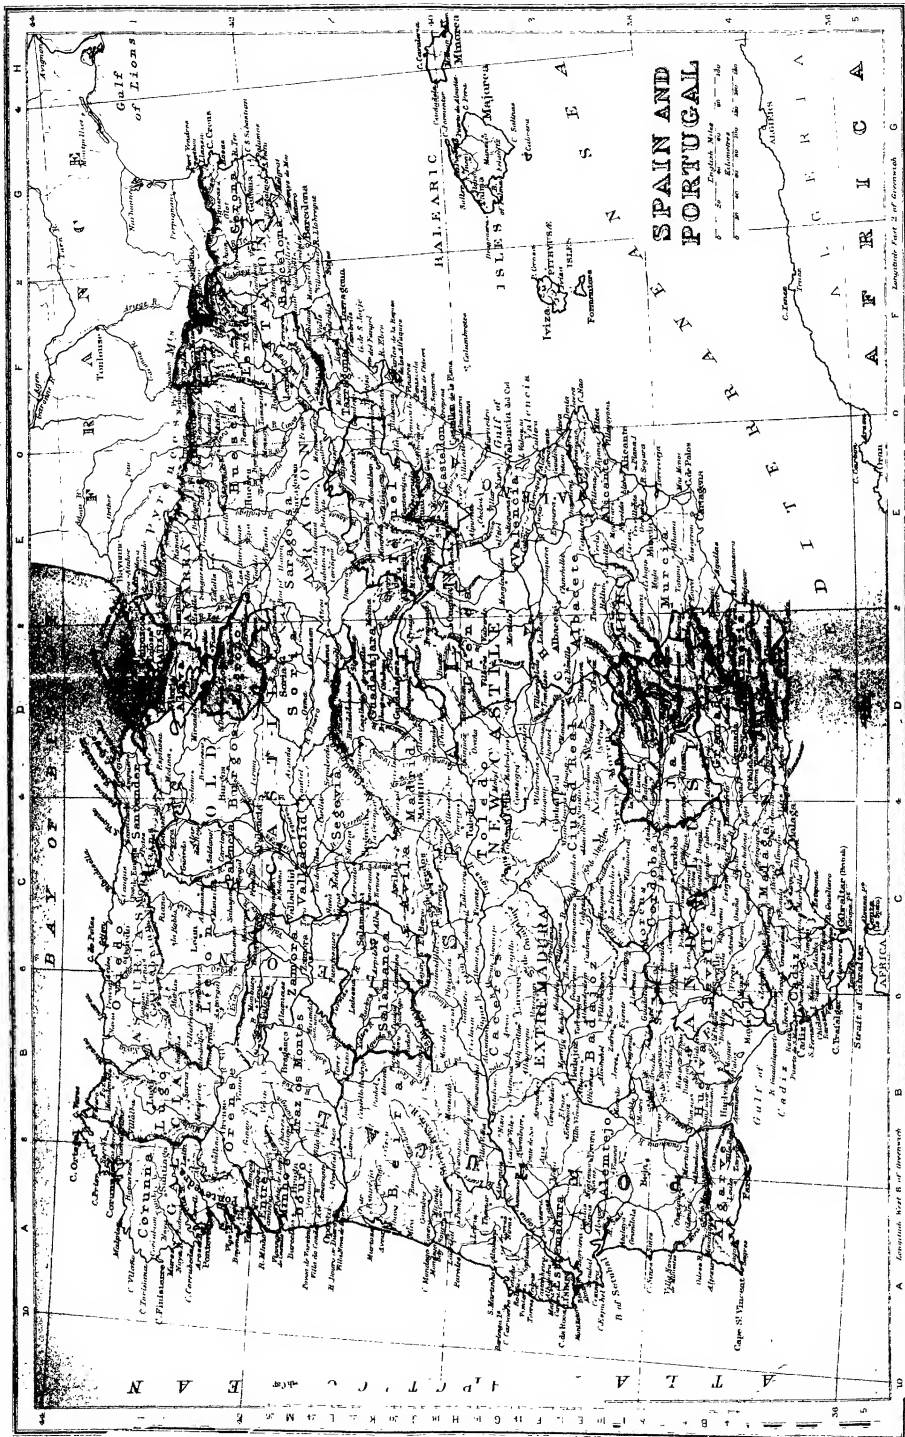

canal here between the two oceans has been dreamt of ever since Cortes's day. A concession was granted and an Anglo-American company formed in 1860, but the political insecurity of the country and the construction of the Panamá railway combined to bring it to an end. An interoceanic railway company founded in 1879 also allowed its concession to lapse; Captain Eads's ship-railway remained a project only; but an ordinary railway was opened in 1894, and again (after rebuilding) in 1907.

Teignmouth (pron. *Tinnmouth*), a seaport and watering-place of Devonshire, 12 miles (by rail 14) S. of Exeter, stands on the north side of the pretty estuary of the Teign, which is spanned by a wooden bridge (1827), 557 yards long. Burned by the Danes in 970, by the French in 1338 and 1690, it has a grassy promenade, the Den or *Dene*, a pier, a public market, baths, St Scholastica's Abbey for Benedictine nuns (1865), &c. *Potters'* clay is dug locally. Pop. 11,000.
